[const]	bool	**include_floating_subc**		Gets a flag indicating whether to include floating subcircuits in the netlist.
	void	**include_floating_subcircuits=**	(bool flag)	Sets a flag indicating whether to include floating subcircuits in the netlist.
	Layout ptr	**internal_layout**		Gets the internal layout
	Cell ptr	**internal_top_cell**		Gets the internal top cell

[const]	bool	**is_extracted?**		Gets a value indicating whether the netlist has been extracted
[const]	bool	**is_persisted?**	(const Region layer)	Returns true, if the given layer is a persisted region.
[const]	bool	**is_persisted?**	(const Texts layer)	Returns true, if the given layer is a persisted texts collection.
	void	**join_net_names**	(string pattern)	Specifies another pattern for implicit joining of nets for the top level cell.
	void	**join_net_names**	(string cell_pattern, string pattern)	Specifies another pattern for implicit joining of nets for the cells from the given cell pattern.
	void	**join_nets**	(string[] net_names)	Specifies another name list for explicit joining of nets for the top level cell.
	void	**join_nets**	(string cell_pattern, string[] net_names)	Specifies another name list for explicit joining of nets for the cells from the given cell pattern.
	void	**keep_dss**		Resumes ownership over the DSS object if created with an external one.
	new Region ptr	**layer_by_index**	(unsigned int index)	Gets a layer object for the given index.
	new Region ptr	**layer_by_name**	(string name)	Gets a layer object for the given name.
[const]	string	**layer_name**	(const ShapeCollection l)	Gets the name of the given layer
[const]	string	**layer_name**	(unsigned int l)	Gets the name of the given layer (by index)
[const]	string[]	**layer_names**		Returns a list of names of the layer kept inside the LayoutToNetlist object.
[const]	unsigned int	**layer_of**	(const Region l)	Gets the internal layer for a given extraction layer
[const]	unsigned int	**layer_of**	(const Texts l)	Gets the internal layer for a given text collection
	new Region ptr	**make_layer**	(string name =)	Creates a new, empty hierarchical region
	new Region ptr	**make_layer**	(unsigned int layer_index, string name =)	Creates a new hierarchical region representing an original layer
	new Region ptr	**make_polygon_layer**	(unsigned int layer_index, string name =)	Creates a new region representing an original layer taking polygons and texts
	new Texts ptr	**make_text_layer**	(unsigned int layer_index, string name =)	Creates a new region representing an original layer taking texts only
[const]	unsigned long	**max_vertex_count**		
	void	**max_vertex_count=**	(unsigned long n)	Sets the max_vertex_count parameter for the hierarchical network processor

[const]	string	**name**		Gets the name of the database
	void	**name=**	(string name)	Sets the name of the database
[const]	Netlist ptr	**netlist**		gets the netlist extracted (0 if no extraction happened yet)
[const]	string	**original_file**		Gets the original file name of the database
	void	**original_file=**	(string path)	Sets the original file name of the database
	Net ptr	**probe_net**	(const Region of_layer, const DPoint point, SubCircuit ptr[] ptr sc_path_out = nil, Circuit ptr initial_circuit = nil)	Finds the net by probing a specific location on the given layer
	Net ptr	**probe_net**	(const Region of_layer, const Point point, SubCircuit ptr[] ptr sc_path_out = nil, Circuit ptr initial_circuit = nil)	Finds the net by probing a specific location on the given layer
	void	**read**	(string path)	Reads the extracted netlist from the file.
	void	**read_l2n**	(string path)	Reads the extracted netlist from the file.
	void	**register**	(const ShapeCollection l, string n =)	Names the given layer
	void	**reset_extracted**		Resets the extracted netlist and enables re-extraction
[const]	new Region ptr	**shapes_of_net**	(const Net net, const Region of_layer, bool recursive = true, const ICplxTrans trans = unity)	Returns all shapes of a specific net and layer.
[const]	void	**shapes_of_net**	(const Net net, const Region of_layer, bool recursive, Shapes to, unsigned long propid = 0, const ICplxTrans trans = unity)	Sends all shapes of a specific net and layer to the given Shapes container.
	void	**soft_connect**	(const Region a, const Region b)	Defines an inter-layer connection for the given layers in soft mode.
	void	**soft_connect**	(const Region a, const Texts b)	Defines an inter-layer connection for the given layers in soft mode.
	void	**soft_connect**	(const Texts a, const Region b)	Defines an inter-layer connection for the given layers in soft mode.

	unsigned long	**soft_connect_global**	(const Region l, string global_net_name)	Defines a connection of the given layer with a global net in soft mode.
	unsigned long	**soft_connect_global**	(const Texts l, string global_net_name)	Defines a connection of the given text layer with a global net in soft mode.
[const]	int	**threads**		Gets the number of threads to use for operations which support multiple threads
	void	**threads=**	(int n)	Sets the number of threads to use for operations which support multiple threads
[const]	bool	**top_level_mode**		Gets a flag indicating whether top level mode is enabled.
	void	**top_level_mode=**	(bool flag)	Sets a flag indicating whether top level mode is enabled.
	void	**write**	(string path, bool short_format = false)	Writes the extracted netlist to a file.
	void	**write_l2n**	(string path, bool short_format = false)	Writes the extracted netlist to a file.

Public static methods and constants

[static,const]	LayoutToNetlist::BuildNetHiera	**BNH_Disconnected**	This constant tells build_net and build_all_nets to produce local nets without connections to subcircuits (used for the "hier_mode" parameter).
[static,const]	LayoutToNetlist::BuildNetHierarchyMode	**BNH_Flatten**	This constant tells build_net and build_all_nets to flatten the nets (used for the "hier_mode" parameter).
[static,const]	LayoutToNetlist::BuildNetHiera	**BNH_SubcircuitCell**	This constant tells build_net and build_all_nets to produce a hierarchy of subcircuit cells per net (used for the "hier_mode" parameter).

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const,iter]	LogEntryData	**each_error**	Use of this method is deprecated. Use each_log_entry instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

BNH_Disconnected

Signature: *[static,const]* LayoutToNetlist::BuildNetHierarchyMode **BNH_Disconnected**

Description: This constant tells build_net and build_all_nets to produce local nets without connections to subcircuits (used for the "hier_mode" parameter).

Python specific notes:
The object exposes a readable attribute 'BNH_Disconnected'. This is the getter.

BNH_Flatten

Signature: *[static,const]* LayoutToNetlist::BuildNetHierarchyMode **BNH_Flatten**

Description: This constant tells build_net and build_all_nets to flatten the nets (used for the "hier_mode" parameter).

Python specific notes:
The object exposes a readable attribute 'BNH_Flatten'. This is the getter.

BNH_SubcircuitCells

Signature: *[static,const]* LayoutToNetlist::BuildNetHierarchyMode **BNH_SubcircuitCells**

Description: This constant tells build_net and build_all_nets to produce a hierarchy of subcircuit cells per net (used for the "hier_mode" parameter).

Python specific notes:
The object exposes a readable attribute 'BNH_SubcircuitCells'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is

known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void _**unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

antenna_check

(1) Signature: Region **antenna_check** (const Region gate, const Region metal, double ratio, variant[] diodes = [], Texts ptr texts = nil)

Description: Runs an antenna check on the extracted clusters

The antenna check will traverse all clusters and run an antenna check for all root clusters. The antenna ratio is defined by the total area of all "metal" shapes divided by the total area of all "gate" shapes on the cluster. Of all clusters where the antenna ratio is larger than the limit ratio all metal shapes are copied to the output region as error markers.

The simple call is:

```
l2n = ... # a LayoutToNetlist object
l2n.extract_netlist
# check for antenna ratio 10.0 of metal vs. poly:
errors = l2n.antenna(poly, metal, 10.0)
```

You can include diodes which rectify the antenna effect. Provide recognition layers for theses diodes and include them in the connections. Then specify the diode layers in the antenna call:

```
...
# include diode_layer1:
errors = l2n.antenna(poly, metal, 10.0, [ diode_layer1 ])
# include diode_layer1 and diode_layer2:errors = l2n.antenna(poly, metal,
 10.0, [ diode_layer1, diode_layer2 ])
```

Diodes can be configured to partially reduce the antenna effect depending on their area. This will make the diode_layer1 increase the ratio by 50.0 per square micrometer area of the diode:

```
...
# diode_layer1 increases the ratio by 50 per square micrometer area:
errors = l2n.antenna(poly, metal, 10.0 [ [ diode_layer, 50.0 ] ])
```

If 'texts' is non-nil, this text collection will receive labels explaining the error in terms of area values and relevant ratio.

The 'texts' parameter has been added in version 0.27.11.

(2) Signature: Region **antenna_check** (const Region gate, double gate_perimeter_factor, const Region metal, double metal_perimeter_factor, double ratio, variant[] diodes = [], Texts ptr texts = nil)

Description: Runs an antenna check on the extracted clusters taking the perimeter into account

This version of the antenna_check method allows taking the perimeter of gate or metal into account. The effective area is computed using:

```
Aeff = A + P * t
```

Here Aeff is the area used in the check, A is the polygon area, P the perimeter and t the perimeter factor. This formula applies to gate polygon area/perimeter with 'gate_perimeter_factor' for t and metal polygon area/perimeter with 'metal_perimeter_factor'. The perimeter_factor has the dimension of micrometers and can be thought of as the width of the material. Essentially the side walls of the material are taking into account for the surface area as well.

This variant has been introduced in version 0.26.6.

(3) Signature: Region **antenna_check** (const Region gate, double gate_area_factor, double gate_perimeter_factor, const Region metal, double metal_area_factor, double metal_perimeter_factor, double ratio, variant[] diodes = [], Texts ptr texts = nil)

Description: Runs an antenna check on the extracted clusters taking the perimeter into account and providing an area factor

This (most generic) version of the antenna_check method allows taking the perimeter of gate or metal into account and also provides a scaling factor for the area part. The effective area is computed using:

```
Aeff = A * f + P * t
```

Here f is the area factor and t the perimeter factor. A is the polygon area and P the polygon perimeter. A use case for this variant is to set the area factor to zero. This way, only perimeter contributions are considered.

This variant has been introduced in version 0.26.6.

area_ratio

Signature: *[const]* double **area_ratio**

Description: Gets the area_ratio parameter for the hierarchical network processor

See area_ratio= for details about this attribute.

Python specific notes:
The object exposes a readable attribute 'area_ratio'. This is the getter.

area_ratio=

Signature: void **area_ratio=** (double r)

Description: Sets the area_ratio parameter for the hierarchical network processor

This parameter controls splitting of large polygons in order to reduce the error made by the bounding box approximation.

Python specific notes:
The object exposes a writable attribute 'area_ratio'. This is the setter.

build_all_nets

Signature: *[const]* void **build_all_nets** (const CellMapping cmap, Layout target, map<unsigned int,const Region ptr> lmap, variant net_cell_name_prefix = nil, variant netname_prop = nil, LayoutToNetlist::BuildNetHierarchyMode hier_mode = BNH_Flatten, variant circuit_cell_name_prefix = nil, variant device_cell_name_prefix = nil)

Description: Builds a full hierarchical representation of the nets

cmap:	The mapping of internal layout to target layout for the circuit mapping
target:	The target layout
lmap:	Target layer indexes (keys) and net regions (values)
hier_mode:	See description of this method
netname_prop:	An (optional) property name to which to attach the net name
circuit_cell_name_prefix:	See method description
net_cell_name_prefix:	See method description
device_cell_name_prefix:	See above

This method copies all nets into cells corresponding to the circuits. It uses the 'cmap' object to determine the target cell (create it with "cell_mapping_into" or "const_cell_mapping_into"). If no mapping is provided for a specific circuit cell, the nets are copied into the next mapped parent as many times as the circuit cell appears there (circuit flattening).

The method has three net annotation modes:

- No annotation (net_cell_name_prefix == nil and netname_prop == nil): the shapes will be put into the target cell simply.
- Net name property (net_cell_name_prefix == nil and netname_prop != nil): the shapes will be annotated with a property named with netname_prop and containing the net name string.
- Individual subcells per net (net_cell_name_prefix != 0): for each net, a subcell is created and the net shapes will be put there (name of the subcell = net_cell_name_prefix + net name). (this mode can be combined with netname_prop too).

In addition, net hierarchy is covered in three ways:

- No connection indicated (hier_mode == BNH_Disconnected: the net shapes are simply put into their respective circuits. The connections are not indicated.
- Subnet hierarchy (hier_mode == BNH_SubcircuitCells): for each root net, a full hierarchy is built to accommodate the subnets (see build_net in recursive mode).
- Flat (hier_mode == BNH_Flatten): each net is flattened and put into the circuit it belongs to.

If a device cell name prefix is given, cells will be produced for each device abstract using a name like device_cell_name_prefix + device name. Otherwise the device shapes are treated as part of the net.

build_net

Signature: *[const]* void **build_net** (const Net net, Layout target, Cell target_cell, map<unsigned int,const Region ptr> lmap, variant netname_prop = nil, LayoutToNetlist::BuildNetHierarchyMode hier_mode = BNH_Flatten, variant circuit_cell_name_prefix = nil, variant device_cell_name_prefix = nil)

Description: Builds a net representation in the given layout and cell

target:	The target layout
target_cell:	The target cell
lmap:	Target layer indexes (keys) and net regions (values)
hier_mode:	See description of this method
netname_prop:	An (optional) property name to which to attach the net name
cell_name_prefix:	Chooses recursive mode if non-null
device_cell_name_prefix:	See above

This method puts the shapes of a net into the given target cell using a variety of options to represent the net name and the hierarchy of the net.

If the netname_prop name is not nil, a property with the given name is created and assigned the net name.

Net hierarchy is covered in three ways:

- No connection indicated (hier_mode == BNH_Disconnected: the net shapes are simply put into their respective circuits. The connections are not indicated.
- Subnet hierarchy (hier_mode == BNH_SubcircuitCells): for each root net, a full hierarchy is built to accommodate the subnets (see build_net in recursive mode).
- Flat (hier_mode == BNH_Flatten): each net is flattened and put into the circuit it belongs to.

If a device cell name prefix is given, cells will be produced for each device abstract using a name like device_cell_name_prefix + device name. Otherwise the device shapes are treated as part of the net.

build_nets

Signature: *[const]* void **build_nets** (const Net ptr[] nets, const CellMapping cmap, Layout target, map<unsigned int,const Region ptr> lmap, variant net_cell_name_prefix = nil, variant netname_prop = nil, LayoutToNetlist::BuildNetHierarchyMode hier_mode = BNH_Flatten, variant circuit_cell_name_prefix = nil, variant device_cell_name_prefix = nil)

Description: Like build_all_nets, but with the ability to select some nets.

cell_mapping_into

(1) Signature: CellMapping **cell_mapping_into** (Layout layout, Cell cell, bool with_device_cells = false)

Description: Creates a cell mapping for copying shapes from the internal layout to the given target layout.

If 'with_device_cells' is true, cells will be produced for devices. These are cells not corresponding to circuits, so they are disabled normally. Use this option, if you want to access device terminal shapes per device.

CAUTION: this function may create new cells in 'layout'. Use const_cell_mapping_into if you want to use the target layout's hierarchy and not modify it.

(2) Signature: CellMapping **cell_mapping_into** (Layout layout, Cell cell, const Net ptr[] nets, bool with_device_cells = false)

Description: Creates a cell mapping for copying shapes from the internal layout to the given target layout.

This version will only create cells which are required to represent the nets from the 'nets' argument.

If 'with_device_cells' is true, cells will be produced for devices. These are cells not corresponding to circuits, so they are disabled normally. Use this option, if you want to access device terminal shapes per device.

CAUTION: this function may create new cells in 'layout'. Use const_cell_mapping_into if you want to use the target layout's hierarchy and not modify it.

check_extraction_errors

Signature: void **check_extraction_errors**

Description: Raises an exception if extraction errors are present

This method has been introduced in version 0.28.13.

clear_join_net_names

Signature: void **clear_join_net_names**

Description: Clears all implicit net joining expressions.

See extract_netlist for more details about this feature.

This method has been introduced in version 0.27 and replaces the arguments of extract_netlist.

clear_join_nets

Signature: void **clear_join_nets**

Description: Clears all explicit net joining expressions.

See extract_netlist for more details about this feature.

Explicit net joining has been introduced in version 0.27.

connect

(1) Signature: void **connect** (const Region l)

Description: Defines an intra-layer connection for the given layer.

The layer is either an original layer created with make_includelayer and its variants or a derived layer. Certain limitations apply. It's safe to use boolean operations for deriving layers. Other operations are applicable as long as they are capable of delivering hierarchical layers.

(2) Signature: void **connect** (const Region a, const Region b)

Description: Defines an inter-layer connection for the given layers.

The conditions mentioned with intra-layer connect apply for this method too.

(3) Signature: void **connect** (const Region a, const Texts b)

Description: Defines an inter-layer connection for the given layers.

The conditions mentioned with intra-layer connect apply for this method too. As one argument is a (hierarchical) text collection, this method is used to attach net labels to polygons.

This variant has been introduced in version 0.27.

(4) Signature: void **connect** (const Texts a, const Region b)

Description: Defines an inter-layer connection for the given layers.

The conditions mentioned with intra-layer connect apply for this method too. As one argument is a (hierarchical) text collection, this method is used to attach net labels to polygons.

This variant has been introduced in version 0.27.

connect_global

(1) Signature: unsigned long **connect_global** (const Region l, string global_net_name)

Description: Defines a connection of the given layer with a global net.

This method returns the ID of the global net. Use global_net_name to get the name back from the ID.

(2) Signature: unsigned long **connect_global** (const Texts l, string global_net_name)

Description: Defines a connection of the given text layer with a global net.

This method returns the ID of the global net. Use global_net_name to get the name back from the ID.

This variant has been introduced in version 0.27.

const_cell_mapping_into

Signature: CellMapping **const_cell_mapping_into** (const Layout layout, const Cell cell)

Description: Creates a cell mapping for copying shapes from the internal layout to the given target layout.

This version will not create new cells in the target layout. If the required cells do not exist there yet, flatting will happen.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

description

Signature: *[const]* string **description**

Description: Gets the description of the database

Python specific notes:
The object exposes a readable attribute 'description'. This is the getter.

description=

Signature: void **description=** (string description)

Description: Sets the description of the database

Python specific notes:
The object exposes a writable attribute 'description'. This is the setter.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

device_scaling

Signature: *[const]* double **device_scaling**

Description: Gets the device scaling factor

See device_scaling= for details about this attribute.

Python specific notes:
The object exposes a readable attribute 'device_scaling'. This is the getter.

device_scaling=

Signature: void **device_scaling=** (double f)

Description: Sets the device scaling factor

This factor will scale the physical properties of the extracted devices accordingly. The scale factor applies an isotropic shrink (<1) or expansion (>1).

Python specific notes:
The object exposes a writable attribute 'device_scaling'. This is the setter.

dss

Signature: DeepShapeStore **dss**

Description: Gets a reference to the internal DSS object.

each_error

Signature: *[const,iter]* LogEntryData **each_error**

Description: Iterates over all log entries collected during device and netlist extraction.

Use of this method is deprecated. Use each_log_entry instead

This method has been introduced in version 0.28.13.

each_log_entry

Signature: *[const,iter]* LogEntryData **each_log_entry**

Description: Iterates over all log entries collected during device and netlist extraction.

This method has been introduced in version 0.28.13.

extract_devices

Signature: void **extract_devices** (DeviceExtractorBase extractor, map<string,ShapeCollection ptr> layers)

Description: Extracts devices

See the class description for more details. This method will run device extraction for the given extractor. The layer map is specific for the extractor and uses the region objects derived with make_layer and its variants.

In addition, derived regions can be passed too. Certain limitations apply. It's safe to use boolean operations for deriving layers. Other operations are applicable as long as they are capable of delivering hierarchical layers.

If errors occur, the device extractor will contain theses errors.

extract_netlist

Signature: void **extract_netlist**

Description: Runs the netlist extraction

See the class description for more details.

This method has been made parameter-less in version 0.27. Use include_floating_subcircuits= and join_net_names as substitutes for the arguments of previous versions.

filename

Signature: *[const]* string **filename**

Description: Gets the file name of the database

The filename is the name under which the database is stored or empty if it is not associated with a file.

generator

Signature: *[const]* string **generator**

Description: Gets the generator string.

The generator is the script that created this database.

Python specific notes:
The object exposes a readable attribute 'generator'. This is the getter.

generator=

Signature: void **generator=** (string generator)

Description: Sets the generator string.

Python specific notes:
The object exposes a writable attribute 'generator'. This is the setter.

global_net_name

Signature: *[const]* string **global_net_name** (unsigned long global_net_id)

Description: Gets the global net name for the given global net ID.

include_floating_subcircuits

Signature: *[const]* bool **include_floating_subcircuits**

Description: Gets a flag indicating whether to include floating subcircuits in the netlist.

See include_floating_subcircuits= for details.

This attribute has been introduced in version 0.27.

Python specific notes:
The object exposes a readable attribute 'include_floating_subcircuits'. This is the getter.

include_floating_subcircuits=

Signature: void **include_floating_subcircuits=** (bool flag)

Description: Sets a flag indicating whether to include floating subcircuits in the netlist.

With 'include_floating_subcircuits' set to true, subcircuits with no connection to their parent circuit are still included in the circuit as floating subcircuits. Specifically on flattening this means that these subcircuits are properly propagated to their parent instead of appearing as additional top circuits.

This attribute has been introduced in version 0.27 and replaces the arguments of extract_netlist.

Python specific notes:
The object exposes a writable attribute 'include_floating_subcircuits'. This is the setter.

internal_layout

Signature: Layout ptr **internal_layout**

Description: Gets the internal layout

Usually it should not be required to obtain the internal layout. If you need to do so, make sure not to modify the layout as the functionality of the netlist extractor depends on it.

internal_top_cell

Signature: Cell ptr **internal_top_cell**

Description: Gets the internal top cell

Usually it should not be required to obtain the internal cell. If you need to do so, make sure not to modify the cell as the functionality of the netlist extractor depends on it.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_extracted?

Signature: *[const]* bool **is_extracted?**

Description: Gets a value indicating whether the netlist has been extracted

This method has been introduced in version 0.27.1.

is_persisted?

(1) Signature: *[const]* bool **is_persisted?** (const Region layer)

Description: Returns true, if the given layer is a persisted region.

Persisted layers are kept inside the LayoutToNetlist object and are not released if their object is destroyed. Named layers are persisted, unnamed layers are not. Only persisted, named layers can be put into connect.

(2) Signature: *[const]* bool **is_persisted?** (const Texts layer)

Description: Returns true, if the given layer is a persisted texts collection.

Persisted layers are kept inside the LayoutToNetlist object and are not released if their object is destroyed. Named layers are persisted, unnamed layers are not. Only persisted, named layers can be put into connect.

The variant for Texts collections has been added in version 0.27.

join_net_names

(1) Signature: void **join_net_names** (string pattern)

Description: Specifies another pattern for implicit joining of nets for the top level cell.

Use this method to register a pattern for net labels considered in implicit net joining. Implicit net joining allows connecting multiple parts of the same nets (e.g. supply rails) without need for a physical connection. The pattern specifies labels to look for. When parts are labelled with a name matching the expression, the parts carrying the same name are joined.

This method adds a new pattern. Use clear_join_net_names to clear the registered pattern.

Each pattern is a glob expression. Valid glob expressions are:

- "" no implicit connections.
- "*" to make all labels candidates for implicit connections.
- "VDD" to make all 'VDD" nets candidates for implicit connections.
- "VDD" to make all 'VDD'+suffix nets candidates for implicit connections.
- "{VDD,VSS}" to all VDD and VSS nets candidates for implicit connections.

Label matching is case sensitive.

This method has been introduced in version 0.27 and replaces the arguments of extract_netlist.

(2) Signature: void **join_net_names** (string cell_pattern, string pattern)

Description: Specifies another pattern for implicit joining of nets for the cells from the given cell pattern.

This method allows applying implicit net joining for specific cells, not only for the top cell.

This method adds a new pattern. Use clear_join_net_names to clear the registered pattern.

This method has been introduced in version 0.27 and replaces the arguments of extract_netlist.

join_nets

(1) Signature: void **join_nets** (string[] net_names)

Description: Specifies another name list for explicit joining of nets for the top level cell.

Use this method to join nets from the set of net names. All these nets will be connected together forming a single net. Explicit joining will imply implicit joining for the involved nets - partial nets involved will be connected too (intra-net joining).

This method adds a new name list. Use clear_join_nets to clear the registered pattern.

Explicit net joining has been introduced in version 0.27.

(2) Signature: void **join_nets** (string cell_pattern, string[] net_names)

Description: Specifies another name list for explicit joining of nets for the cells from the given cell pattern.

This method allows applying explicit net joining for specific cells, not only for the top cell.

This method adds a new name list. Use clear_join_nets to clear the registered pattern.

	Explicit net joining has been introduced in version 0.27.
keep_dss	**Signature**: void **keep_dss** **Description**: Resumes ownership over the DSS object if created with an external one.
layer_by_index	**Signature**: new Region ptr **layer_by_index** (unsigned int index) **Description**: Gets a layer object for the given index. Only named layers can be retrieved with this method. The returned object is a copy which represents the named layer.
layer_by_name	**Signature**: new Region ptr **layer_by_name** (string name) **Description**: Gets a layer object for the given name. The returned object is a copy which represents the named layer.
layer_name	**(1) Signature**: *[const]* string **layer_name** (const ShapeCollection l) **Description**: Gets the name of the given layer **(2) Signature**: *[const]* string **layer_name** (unsigned int l) **Description**: Gets the name of the given layer (by index)
layer_names	**Signature**: *[const]* string[] **layer_names** **Description**: Returns a list of names of the layer kept inside the LayoutToNetlist object.
layer_of	**(1) Signature**: *[const]* unsigned int **layer_of** (const Region l) **Description**: Gets the internal layer for a given extraction layer This method is required to derive the internal layer index - for example for investigating the cluster tree. **(2) Signature**: *[const]* unsigned int **layer_of** (const Texts l) **Description**: Gets the internal layer for a given text collection This method is required to derive the internal layer index - for example for investigating the cluster tree. The variant for Texts collections has been added in version 0.27.
make_layer	**(1) Signature**: new Region ptr **make_layer** (string name =) **Description**: Creates a new, empty hierarchical region The name is optional. If given, the layer will already be named accordingly (see register). **(2) Signature**: new Region ptr **make_layer** (unsigned int layer_index, string name =) **Description**: Creates a new hierarchical region representing an original layer 'layer_index' is the layer index of the desired layer in the original layout. This variant produces polygons and takes texts for net name annotation. A variant not taking texts is make_polygon_layer. A Variant only taking texts is make_text_layer. The name is optional. If given, the layer will already be named accordingly (see register).

make_polygon_layer

Signature: new Region ptr **make_polygon_layer** (unsigned int layer_index, string name =)

Description: Creates a new region representing an original layer taking polygons and texts

See make_layer for details.

The name is optional. If given, the layer will already be named accordingly (see register).

make_text_layer

Signature: new Texts ptr **make_text_layer** (unsigned int layer_index, string name =)

Description: Creates a new region representing an original layer taking texts only

See make_layer for details.

The name is optional. If given, the layer will already be named accordingly (see register).

Starting with version 0.27, this method returns a Texts object.

max_vertex_count

Signature: *[const]* unsigned long **max_vertex_count**

Description:

See max_vertex_count= for details about this attribute.

Python specific notes:
The object exposes a readable attribute 'max_vertex_count'. This is the getter.

max_vertex_count=

Signature: void **max_vertex_count=** (unsigned long n)

Description: Sets the max_vertex_count parameter for the hierarchical network processor

This parameter controls splitting of large polygons in order to enhance performance for very big polygons.

Python specific notes:
The object exposes a writable attribute 'max_vertex_count'. This is the setter.

name

Signature: *[const]* string **name**

Description: Gets the name of the database

Python specific notes:
The object exposes a readable attribute 'name'. This is the getter.

name=

Signature: void **name=** (string name)

Description: Sets the name of the database

Python specific notes:
The object exposes a writable attribute 'name'. This is the setter.

netlist

Signature: *[const]* Netlist ptr **netlist**

Description: gets the netlist extracted (0 if no extraction happened yet)

new

(1) Signature: *[static]* new LayoutToNetlist ptr **new** (const RecursiveShapeIterator iter)

Description: Creates a new extractor connected to an original layout

This constructor will attach the extractor to an original layout through the shape iterator.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new LayoutToNetlist ptr **new**

Description: Creates a new and empty extractor object

The main objective for this constructor is to create an object suitable for reading an annotated netlist.

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new LayoutToNetlist ptr **new** (DeepShapeStore ptr dss)

Description: Creates a new extractor object reusing an existing DeepShapeStore object

This constructor can be used if there is a DSS object already from which the shapes can be taken. This version can only be used with register to add layers (regions) inside the 'dss' object.

The make_... methods will not create new layers as there is no particular place defined where to create the layers.

The extractor will not take ownership of the dss object unless you call keep_dss.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new LayoutToNetlist ptr **new** (DeepShapeStore ptr dss, unsigned int layout_index)

Description: Creates a new extractor object reusing an existing DeepShapeStore object

This constructor can be used if there is a DSS object already from which the shapes can be taken. NOTE: in this case, the make_... functions will create new layers inside this DSS. To register existing layers (regions) use register.

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new LayoutToNetlist ptr **new** (string topcell_name, double dbu)

Description: Creates a new extractor object with a flat DSS

topcell_name:	The name of the top cell of the internal flat layout
dbu:	The database unit to use for the internal flat layout

This constructor will create an extractor for flat extraction. Layers registered with register will be flattened. New layers created with make_... will be flat layers.

The database unit is mandatory because the physical parameter extraction for devices requires this unit for translation of layout to physical dimensions.

Python specific notes:
This method is the default initializer of the object.

original_file

Signature: *[const]* string **original_file**

Description: Gets the original file name of the database

The original filename is the layout file from which the netlist DB was created.

Python specific notes:
The object exposes a readable attribute 'original_file'. This is the getter.

original_file=

Signature: void **original_file=** (string path)

Description: Sets the original file name of the database

Python specific notes:
The object exposes a writable attribute 'original_file'. This is the setter.

probe_net

(1) Signature: Net ptr **probe_net** (const Region of_layer, const DPoint point, SubCircuit ptr[] ptr sc_path_out = nil, Circuit ptr initial_circuit = nil)

Description: Finds the net by probing a specific location on the given layer

This method will find a net looking at the given layer at the specific position. It will traverse the hierarchy below if no shape in the requested layer is found in the specified location. The function will report the topmost net from far above the hierarchy of circuits as possible.

If initial_circuit is given, the probing will start from this circuit and from the cell this circuit represents. By default, the probing will start from the top circuit.

If no net is found at all, 0 is returned.

It is recommended to use probe_net on the netlist right after extraction. Optimization functions such as Netlist#purge will remove parts of the net which means shape to net probing may no longer work for these nets.

If non-null and an array, 'sc_path_out' will receive a list of SubCircuits objects which lead to the net from the top circuit of the database.

This variant accepts a micrometer-unit location. The location is given in the coordinate space of the initial cell.

The sc_path_out and initial_circuit parameters have been added in version 0.27.

(2) Signature: Net ptr **probe_net** (const Region of_layer, const Point point, SubCircuit ptr[] ptr sc_path_out = nil, Circuit ptr initial_circuit = nil)

Description: Finds the net by probing a specific location on the given layer

See the description of the other probe_net variant. This variant accepts a database-unit location. The location is given in the coordinate space of the initial cell.

The sc_path_out and initial_circuit parameters have been added in version 0.27.

read

Signature: void **read** (string path)

Description: Reads the extracted netlist from the file.

This method employs the native format of KLayout.

read_l2n

Signature: void **read_l2n** (string path)

Description: Reads the extracted netlist from the file.

This method employs the native format of KLayout.

register

Signature: void **register** (const ShapeCollection l, string n =)

Description: Names the given layer

'l' must be a Region or Texts object. Flat regions or text collections must be registered with this function, before they can be used in connect. Registering will copy the shapes into the LayoutToNetlist object in this step to enable netlist extraction.

Naming a layer allows the system to indicate the layer in various contexts, i.e. when writing the data to a file. Named layers are also persisted inside the LayoutToNetlist object. They are not discarded when the Region object is destroyed.

If required, the system will assign a name automatically. This method has been generalized in version 0.27.

reset_extracted

Signature: void **reset_extracted**

Description: Resets the extracted netlist and enables re-extraction

This method is implicitly called when using connect or connect_global after a netlist has been extracted. This enables incremental connect with re-extraction.

This method has been introduced in version 0.27.1.

shapes_of_net

(1) Signature: *[const]* new Region ptr **shapes_of_net** (const Net net, const Region of_layer, bool recursive = true, const ICplxTrans trans = unity)

Description: Returns all shapes of a specific net and layer.

If 'recursive" is true, the returned region will contain the shapes of all subcircuits too.

The optional 'trans' parameter allows applying a transformation to all shapes. It has been introduced in version 0.28.4.

(2) Signature: *[const]* void **shapes_of_net** (const Net net, const Region of_layer, bool recursive, Shapes to, unsigned long propid = 0, const ICplxTrans trans = unity)

Description: Sends all shapes of a specific net and layer to the given Shapes container.

If 'recursive" is true, the returned region will contain the shapes of all subcircuits too. "prop_id" is an optional properties ID. If given, this property set will be attached to the shapes. The optional 'trans' parameter allows applying a transformation to all shapes. It has been introduced in version 0.28.4.

soft_connect

(1) Signature: void **soft_connect** (const Region a, const Region b)

Description: Defines an inter-layer connection for the given layers in soft mode.

Connects two layers through a soft connection. Soft connections cannot make connections between two different nets. These are directional connections where 'b' is the 'lower' layer (typically high-ohmic substrate or diffusion).

Soft connections have been introduced in version 0.29.

(2) Signature: void **soft_connect** (const Region a, const Texts b)

Description: Defines an inter-layer connection for the given layers in soft mode.

Connects two layers through a soft connection. Soft connections cannot make connections between two different nets. These are directional connections where 'b' is the 'lower' layer (typically high-ohmic substrate or diffusion). As one argument is a (hierarchical) text collection, this method is used to attach net labels to polygons.

Soft connections have been introduced in version 0.29.

(3) Signature: void **soft_connect** (const Texts a, const Region b)

Description: Defines an inter-layer connection for the given layers in soft mode.

Connects two layers through a soft connection. Soft connections cannot make connections between two different nets. These are directional connections where 'b' is the 'lower' layer (typically high-ohmic substrate or diffusion). As one argument is a (hierarchical) text collection, this method is used to attach net labels to polygons.

Soft connections have been introduced in version 0.29.

soft_connect_global

(1) Signature: unsigned long **soft_connect_global** (const Region l, string global_net_name)

Description: Defines a connection of the given layer with a global net in soft mode.

This method returns the ID of the global net. Use global_net_name to get the name back from the ID. Soft connections are directional, where the global net is the 'lower' layer (typically high-ohmic substrate or diffusion).

Soft connections have been introduced in version 0.29.

(2) Signature: unsigned long **soft_connect_global** (const Texts l, string global_net_name)

Description: Defines a connection of the given text layer with a global net in soft mode.

This method returns the ID of the global net. Use global_net_name to get the name back from the ID. Soft connections are directional, where the global net is the 'lower' layer (typically high-ohmic substrate or diffusion).

Soft connections have been introduced in version 0.29.

threads

Signature: *[const]* int **threads**

Description: Gets the number of threads to use for operations which support multiple threads

Python specific notes:
The object exposes a readable attribute 'threads'. This is the getter.

threads=

Signature: void **threads=** (int n)

Description: Sets the number of threads to use for operations which support multiple threads

Python specific notes:
The object exposes a writable attribute 'threads'. This is the setter.

top_level_mode

Signature: *[const]* bool **top_level_mode**

Description: Gets a flag indicating whether top level mode is enabled.

See top_level_mode= for details.

This attribute has been introduced in version 0.28.13.

Python specific notes:
The object exposes a readable attribute 'top_level_mode'. This is the getter.

top_level_mode=

Signature: void **top_level_mode=** (bool flag)

Description: Sets a flag indicating whether top level mode is enabled.

In top level mode, must-connect warnings are turned into errors for example. To enable top level mode, set this attribute to true. By default, top-level mode is turned off.

This attribute has been introduced in version 0.28.13.

Python specific notes:
The object exposes a writable attribute 'top_level_mode'. This is the setter.

write

Signature: void **write** (string path, bool short_format = false)

Description: Writes the extracted netlist to a file.

This method employs the native format of KLayout.

write_l2n

Signature: void **write_l2n** (string path, bool short_format = false)

Description: Writes the extracted netlist to a file.

This method employs the native format of KLayout.

4.168. API reference - Class LayoutToNetlist::BuildNetHierarchyMode

Notation used in Ruby API documentation

Module: db

Description: This class represents the LayoutToNetlist::BuildNetHierarchyMode enum

This class is equivalent to the class LayoutToNetlist::BuildNetHierarchyMode

This enum is used for LayoutToNetlist#build_all_nets and LayoutToNetlist#build_net.

Public constructors

new LayoutToNetlist::BuildNetHierarchyMode ptr	**new**	(int i)	Creates an enum from an integer value
new LayoutToNetlist::BuildNetHierarchyMode ptr	**new**	(string s)	Creates an enum from a string value

Public methods

[const]	bool	**!=**	(const LayoutToNetlist::BuildNetH other)	Compares two enums for inequality
[const]	bool	**!=**	(int other)	Compares an enum with an integer for inequality
[const]	bool	**<**	(const LayoutToNetlist::BuildNetH other)	Returns true if the first enum is less (in the enum symbol order) than the second
[const]	bool	**<**	(int other)	Returns true if the enum is less (in the enum symbol order) than the integer value
[const]	bool	**==**	(const LayoutToNetlist::BuildNetH other)	Compares two enums
[const]	bool	**==**	(int other)	Compares an enum with an integer value
[const]	int	**hash**		Gets the hash value from the enum
[const]	string	**inspect**		Converts an enum to a visual string
[const]	int	**to_i**		Gets the integer value from the enum
[const]	string	**to_s**		Gets the symbolic string from an enum

Public static methods and constants

[static,const]	LayoutToNetlist::BuildNetHiera	**BNH_Disconnected**	This constant tells build_net and build_all_nets to produce local nets without connections to subcircuits (used for the "hier_mode" parameter).

[static,const]	LayoutToNetlist::BuildNetHierarchyMode **BNH_Flatten**	This constant tells build_net and build_all_nets to flatten the nets (used for the "hier_mode" parameter).
[static,const]	LayoutToNetlist::BuildNetHierarchyMode **BNH_SubcircuitCell**	This constant tells build_net and build_all_nets to produce a hierarchy of subcircuit cells per net (used for the "hier_mode" parameter).

Detailed description

!=

(1) Signature: *[const]* bool **!=** (const LayoutToNetlist::BuildNetHierarchyMode other)

Description: Compares two enums for inequality

(2) Signature: *[const]* bool **!=** (int other)

Description: Compares an enum with an integer for inequality

<

(1) Signature: *[const]* bool **<** (const LayoutToNetlist::BuildNetHierarchyMode other)

Description: Returns true if the first enum is less (in the enum symbol order) than the second

(2) Signature: *[const]* bool **<** (int other)

Description: Returns true if the enum is less (in the enum symbol order) than the integer value

==

(1) Signature: *[const]* bool **==** (const LayoutToNetlist::BuildNetHierarchyMode other)

Description: Compares two enums

(2) Signature: *[const]* bool **==** (int other)

Description: Compares an enum with an integer value

BNH_Disconnected

Signature: *[static,const]* LayoutToNetlist::BuildNetHierarchyMode **BNH_Disconnected**

Description: This constant tells build_net and build_all_nets to produce local nets without connections to subcircuits (used for the "hier_mode" parameter).

Python specific notes:
The object exposes a readable attribute 'BNH_Disconnected'. This is the getter.

BNH_Flatten

Signature: *[static,const]* LayoutToNetlist::BuildNetHierarchyMode **BNH_Flatten**

Description: This constant tells build_net and build_all_nets to flatten the nets (used for the "hier_mode" parameter).

Python specific notes:
The object exposes a readable attribute 'BNH_Flatten'. This is the getter.

BNH_SubcircuitCells

Signature: *[static,const]* LayoutToNetlist::BuildNetHierarchyMode **BNH_SubcircuitCells**

Description: This constant tells build_net and build_all_nets to produce a hierarchy of subcircuit cells per net (used for the "hier_mode" parameter).

Python specific notes:
The object exposes a readable attribute 'BNH_SubcircuitCells'. This is the getter.

hash

Signature: *[const]* int **hash**

Description: Gets the hash value from the enum

Python specific notes:
This method is also available as 'hash(object)'.

inspect

Signature: *[const]* string **inspect**

Description: Converts an enum to a visual string

Python specific notes:
This method is also available as 'repr(object)'.

new

(1) Signature: *[static]* new LayoutToNetlist::BuildNetHierarchyMode ptr **new** (int i)

Description: Creates an enum from an integer value

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new LayoutToNetlist::BuildNetHierarchyMode ptr **new** (string s)

Description: Creates an enum from a string value

Python specific notes:
This method is the default initializer of the object.

to_i

Signature: *[const]* int **to_i**

Description: Gets the integer value from the enum

Python specific notes:
This method is also available as 'int(object)'.

to_s

Signature: *[const]* string **to_s**

Description: Gets the symbolic string from an enum

Python specific notes:
This method is also available as 'str(object)'.

4.169. API reference - Class DeepShapeStore

Notation used in Ruby API documentation

Module: db

Description: An opaque layout heap for the deep region processor

This class is used for keeping intermediate, hierarchical data for the deep region processor. It is used in conjunction with the region constructor to create a deep (hierarchical) region.

```
layout = ... # a layout
layer = ...  # a layer
cell = ...   # a cell (initial cell for the deep region)
dss = RBA::DeepShapeStore::new
region = RBA::Region::new(cell.begin(layer), dss)
```

The DeepShapeStore object also supplies some configuration options for the operations acting on the deep regions. See for example threads=.

This class has been introduced in version 0.26.

Public constructors

new DeepShapeStore ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**add_breakout_cell**	(unsigned int layout_index, unsigned int[] cell_index)	Adds a cell indexe to the breakout cell list for the given layout inside the store
	void	**add_breakout_cells**	(unsigned int layout_index, unsigned int[] cells)	Adds cell indexes to the breakout cell list for the given layout inside the store
	void	**add_breakout_cells**	(unsigned int layout_index, string pattern)	Adds cells (given by a cell name pattern) to the breakout cell list for the given layout inside the store

	void	add_breakout_cells	(string pattern)	Adds cells (given by a cell name pattern) to the breakout cell list to all layouts inside the store
	void	clear_breakout_cells	(unsigned int layout_index)	Clears the breakout cells
	void	clear_breakout_cells		Clears the breakout cells
[const]	bool	is_singular?		Gets a value indicating whether there is a single layout variant
[const]	double	max_area_ratio		Gets the max. area ratio.
	void	max_area_ratio=	(double ratio)	Sets the max. area ratio for bounding box vs. polygon area
[const]	unsigned long	max_vertex_count		Gets the maximum vertex count.
	void	max_vertex_count=	(unsigned long count)	Sets the maximum vertex count default value
	void	pop_state		Restores the store's state on the state state
	void	push_state		Pushes the store's state on the state state
[const]	bool	reject_odd_polygons		Gets a flag indicating whether to reject odd polygons.
	void	reject_odd_polygons=	(bool count)	Sets a flag indicating whether to reject odd polygons
	void	set_breakout_cells	(unsigned int layout_index, unsigned int[] cells)	Sets the breakout cell list (as cell indexes) for the given layout inside the store
	void	set_breakout_cells	(unsigned int layout_index, string pattern)	Sets the breakout cell list (as cell name pattern) for the given layout inside the store
	void	set_breakout_cells	(string pattern)	Sets the breakout cell list (as cell name pattern) for the all layouts inside the store
	void	subcircuit_hierarchy_for_n	(bool value)	Sets a value indicating whether to build a subcircuit hierarchy per net
	void	subcircuit_hierarchy_for_nets=	(bool value)	Gets a value indicating whether to build a subcircuit hierarchy per net
[const]	int	text_enlargement		Gets the text enlargement value.
	void	text_enlargement=	(int value)	Sets the text enlargement value
[const]	variant	text_property_name		Gets the text property name.
	void	text_property_name=	(variant name)	Sets the text property name.
[const]	int	threads		Gets the number of threads.

	void	threads=	(int n)	Sets the number of threads to allocate for the hierarchical processor
[const]	bool	wants_all_cells		Gets a flag wether to copy the full hierarchy for the working layouts
	void	wants_all_cells=	(bool flag)	Sets a flag wether to copy the full hierarchy for the working layouts

Deprecated methods (protected, public, static, non-static and constructors)

	void	create	Use of this method is deprecated. Use _create instead
	void	destroy	Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	is_const_object?	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is

known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

add_breakout_cell

Signature: void **add_breakout_cell** (unsigned int layout_index, unsigned int[] cell_index)

Description: Adds a cell indexe to the breakout cell list for the given layout inside the store

See clear_breakout_cells for an explanation of breakout cells.

This method has been added in version 0.26.1

add_breakout_cells

(1) Signature: void **add_breakout_cells** (unsigned int layout_index, unsigned int[] cells)

Description: Adds cell indexes to the breakout cell list for the given layout inside the store

See clear_breakout_cells for an explanation of breakout cells.

This method has been added in version 0.26.1

(2) Signature: void **add_breakout_cells** (unsigned int layout_index, string pattern)

Description: Adds cells (given by a cell name pattern) to the breakout cell list for the given layout inside the store

See clear_breakout_cells for an explanation of breakout cells.

This method has been added in version 0.26.1

(3) Signature: void **add_breakout_cells** (string pattern)

Description: Adds cells (given by a cell name pattern) to the breakout cell list to all layouts inside the store

See clear_breakout_cells for an explanation of breakout cells.

This method has been added in version 0.26.1

clear_breakout_cells

(1) Signature: void **clear_breakout_cells** (unsigned int layout_index)

Description: Clears the breakout cells

Breakout cells are a feature by which hierarchy handling can be disabled for specific cells. If cells are specified as breakout cells, they don't interact with neighbor or parent cells, hence are virtually isolated. Breakout cells are useful to shortcut hierarchy evaluation for cells which are otherwise difficult to handle. An example are memory array cells with overlaps to their neighbors: a precise handling of such cells would generate variants and the boundary of the array. Although precise, this behavior leads to partial flattening and propagation of shapes. In consequence, this will also result in wrong device detection in LVS applications. In such cases, these array cells can be declared 'breakout cells' which makes them isolated entities and variant generation does not happen.

See also set_breakout_cells and add_breakout_cells.

	This method has been added in version 0.26.1 **(2) Signature**: void **clear_breakout_cells** **Description**: Clears the breakout cells See the other variant of clear_breakout_cells for details. This method has been added in version 0.26.1
create	**Signature**: void **create** **Description**: Ensures the C++ object is created Use of this method is deprecated. Use _create instead Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
destroy	**Signature**: void **destroy** **Description**: Explicitly destroys the object Use of this method is deprecated. Use _destroy instead Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
destroyed?	**Signature**: *[const]* bool **destroyed?** **Description**: Returns a value indicating whether the object was already destroyed Use of this method is deprecated. Use _destroyed? instead This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
is_const_object?	**Signature**: *[const]* bool **is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.
is_singular?	**Signature**: *[const]* bool **is_singular?** **Description**: Gets a value indicating whether there is a single layout variant Specifically for network extraction, singular DSS objects are required. Multiple layouts may be present if different sources of layouts have been used. Such DSS objects are not usable for network extraction.
max_area_ratio	**Signature**: *[const]* double **max_area_ratio** **Description**: Gets the max. area ratio. **Python specific notes:** The object exposes a readable attribute 'max_area_ratio'. This is the getter.
max_area_ratio=	**Signature**: void **max_area_ratio=** (double ratio) **Description**: Sets the max. area ratio for bounding box vs. polygon area

This parameter is used to simplify complex polygons. It is used by create_polygon_layer with the default parameters. It's also used by boolean operations when they deliver their output.

Python specific notes:
The object exposes a writable attribute 'max_area_ratio'. This is the setter.

max_vertex_count

Signature: *[const]* unsigned long **max_vertex_count**

Description: Gets the maximum vertex count.

Python specific notes:
The object exposes a readable attribute 'max_vertex_count'. This is the getter.

max_vertex_count=

Signature: void **max_vertex_count=** (unsigned long count)

Description: Sets the maximum vertex count default value

This parameter is used to simplify complex polygons. It is used by create_polygon_layer with the default parameters. It's also used by boolean operations when they deliver their output.

Python specific notes:
The object exposes a writable attribute 'max_vertex_count'. This is the setter.

new

Signature: *[static]* new DeepShapeStore ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

pop_state

Signature: void **pop_state**

Description: Restores the store's state on the state state

This will restore the state pushed by push_state.

This method has been added in version 0.26.1

push_state

Signature: void **push_state**

Description: Pushes the store's state on the state state

This will save the stores state (threads, max_vertex_count, max_area_ratio, breakout cells ...) on the state stack. pop_state can be used to restore the state.

This method has been added in version 0.26.1

reject_odd_polygons

Signature: *[const]* bool **reject_odd_polygons**

Description: Gets a flag indicating whether to reject odd polygons.

This attribute has been introduced in version 0.27.

Python specific notes:
The object exposes a readable attribute 'reject_odd_polygons'. This is the getter.

reject_odd_polygons=

Signature: void **reject_odd_polygons=** (bool count)

Description: Sets a flag indicating whether to reject odd polygons

Some kind of 'odd' (e.g. non-orientable) polygons may spoil the functionality because they cannot be handled properly. By using this flag, the shape store we reject these kind of polygons. The default is 'accept' (without warning).

This attribute has been introduced in version 0.27.

Python specific notes:

The object exposes a writable attribute 'reject_odd_polygons'. This is the setter.

set_breakout_cells

(1) Signature: void **set_breakout_cells** (unsigned int layout_index, unsigned int[] cells)

Description: Sets the breakout cell list (as cell indexes) for the given layout inside the store

See clear_breakout_cells for an explanation of breakout cells.

This method has been added in version 0.26.1

(2) Signature: void **set_breakout_cells** (unsigned int layout_index, string pattern)

Description: Sets the breakout cell list (as cell name pattern) for the given layout inside the store

See clear_breakout_cells for an explanation of breakout cells.

This method has been added in version 0.26.1

(3) Signature: void **set_breakout_cells** (string pattern)

Description: Sets the breakout cell list (as cell name pattern) for the all layouts inside the store

See clear_breakout_cells for an explanation of breakout cells.

This method has been added in version 0.26.1

subcircuit_hierarchy_for_nets=

(1) Signature: void **subcircuit_hierarchy_for_nets=** (bool value)

Description: Sets a value indicating whether to build a subcircuit hierarchy per net

This flag is used to determine the way, net subcircuit hierarchies are built: when true, subcells are created for subcircuits on a net. Otherwise the net shapes are produced flat inside the cell they appear on.

This attribute has been introduced in version 0.28.4

Python specific notes:
The object exposes a writable attribute 'subcircuit_hierarchy_for_nets'. This is the setter.

(2) Signature: void **subcircuit_hierarchy_for_nets=** (bool value)

Description: Gets a value indicating whether to build a subcircuit hierarchy per net

See subcircuit_hierarchy_for_nets= for details.

This attribute has been introduced in version 0.28.4

Python specific notes:
The object exposes a writable attribute 'subcircuit_hierarchy_for_nets'. This is the setter.

text_enlargement

Signature: *[const]* int **text_enlargement**

Description: Gets the text enlargement value.

Python specific notes:
The object exposes a readable attribute 'text_enlargement'. This is the getter.

text_enlargement=

Signature: void **text_enlargement=** (int value)

Description: Sets the text enlargement value

If set to a non-negative value, text objects are converted to boxes with the given enlargement (width = 2 * enlargement). The box centers are identical to the original location of the text. If this value is negative (the default), texts are ignored.

Python specific notes:
The object exposes a writable attribute 'text_enlargement'. This is the setter.

text_property_name

Signature: *[const]* variant **text_property_name**

Description: Gets the text property name.

Python specific notes:
The object exposes a readable attribute 'text_property_name'. This is the getter.

text_property_name=

Signature: void **text_property_name=** (variant name)

Description: Sets the text property name.

If set to a non-null variant, text strings are attached to the generated boxes as properties with this particular name. This option has an effect only if the text_enlargement property is not negative. By default, the name is empty.

Python specific notes:
The object exposes a writable attribute 'text_property_name'. This is the setter.

threads

Signature: *[const]* int **threads**

Description: Gets the number of threads.

Python specific notes:
The object exposes a readable attribute 'threads'. This is the getter.

threads=

Signature: void **threads=** (int n)

Description: Sets the number of threads to allocate for the hierarchical processor

Python specific notes:
The object exposes a writable attribute 'threads'. This is the setter.

wants_all_cells

Signature: *[const]* bool **wants_all_cells**

Description: Gets a flag wether to copy the full hierarchy for the working layouts

This attribute has been introduced in version 0.28.10.

Python specific notes:
The object exposes a readable attribute 'wants_all_cells'. This is the getter.

wants_all_cells=

Signature: void **wants_all_cells=** (bool flag)

Description: Sets a flag wether to copy the full hierarchy for the working layouts

The DeepShapeStore object keeps a copy of the original hierarchy internally for the working layouts. By default, this hierarchy is mapping only non-empty cells. While the operations proceed, more cells may need to be added. This conservative approach saves some memory, but the update operations may reduce overall performance. Setting this flag to 'true' switches to a mode where the full hierarchy is copied always. This will take more memory but may save CPU time.

This attribute has been introduced in version 0.28.10.

Python specific notes:
The object exposes a writable attribute 'wants_all_cells'. This is the setter.

4.170. API reference - Class NetlistCompareLogger

Notation used in Ruby API documentation

Module: db

Description: A base class for netlist comparer event receivers

See GenericNetlistCompareLogger for custom implementations of such receivers.

Public constructors

new NetlistCompareLogger ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference
	void	**_manage**	Marks the object as managed by the script side.
	void	**_unmanage**	Marks the object as no longer owned by the script side.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

	Use of this method is deprecated. Use _destroyed? instead This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
is_const_object?	**Signature**: *[const]* bool **is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.
new	**Signature**: *[static]* new NetlistCompareLogger ptr **new** **Description**: Creates a new object of this class **Python specific notes:** This method is the default initializer of the object.

4.171. API reference - Class GenericNetlistCompareLogger

Notation used in Ruby API documentation

Module: db

Description: An event receiver for the netlist compare feature.

Class hierarchy: GenericNetlistCompareLogger » NetlistCompareLogger

The NetlistComparer class will send compare events to a logger derived from this class. Use this class to implement your own logger class. You can override on of its methods to receive certain kind of events. This class has been introduced in version 0.26.

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[virtual]	void	**begin_circuit**	(const Circuit ptr a, const Circuit ptr b)	This function is called when a new circuit is compared.
[virtual]	void	**begin_netlist**	(const Netlist ptr a, const Netlist ptr b)	This function is called at the beginning of the compare process.
[virtual]	void	**circuit_mismatch**	(const Circuit ptr a, const Circuit ptr b, string msg)	This function is called when circuits can't be compared.
[virtual]	void	**circuit_skipped**	(const Circuit ptr a, const Circuit ptr b, string msg)	This function is called when circuits can't be compared.
[virtual]	void	**device_class_mismat**	(const DeviceClass ptr a, const DeviceClass ptr b, string msg)	This function is called when device classes can't be compared.
[virtual]	void	**device_mismatch**	(const Device ptr a, const Device ptr b, string msg)	This function is called when two devices can't be paired.
[virtual]	void	**end_circuit**	(const Circuit ptr a, const Circuit ptr b, bool matching, string msg)	This function is called at the end of the compare process.
[virtual]	void	**end_netlist**	(const Netlist ptr a, const Netlist ptr b)	This function is called at the end of the compare process.

[virtual]	void	log_entry	(Severity level, string msg)	Issues an entry for the compare log.
[virtual]	void	match_ambiguous_nets	(const Net ptr a, const Net ptr b, string msg)	This function is called when two nets are identified, but this choice is ambiguous.
[virtual]	void	match_devices	(const Device ptr a, const Device ptr b)	This function is called when two devices are identified.
[virtual]	void	match_devices_with_different_device_classes	(const Device ptr a, const Device ptr b)	This function is called when two devices are identified but have different device classes.
[virtual]	void	match_devices_with_	(const Device ptr a, const Device ptr b)	This function is called when two devices are identified but have different parameters.
[virtual]	void	match_nets	(const Net ptr a, const Net ptr b)	This function is called when two nets are identified.
[virtual]	void	match_pins	(const Pin ptr a, const Pin ptr b)	This function is called when two pins are identified.
[virtual]	void	match_subcircuits	(const SubCircuit ptr a, const SubCircuit ptr b)	This function is called when two subcircuits are identified.
[virtual]	void	net_mismatch	(const Net ptr a, const Net ptr b, string msg)	This function is called when a net can't be paired.
[virtual]	void	pin_mismatch	(const Pin ptr a, const Pin ptr b, string msg)	This function is called when two pins can't be paired.
[virtual]	void	subcircuit_mismatch	(const SubCircuit ptr a, const SubCircuit ptr b, string msg)	This function is called when two subcircuits can't be paired.

Public static methods and constants

[static,const]	Severity	Error	Specifies error severity (preferred action is stop)
[static,const]	Severity	Info	Specifies info severity (print if requested, otherwise silent)
[static,const]	Severity	NoSeverity	Specifies no particular severity (default)
[static,const]	Severity	Warning	Specifies warning severity (log with high priority, but do not stop)

Detailed description

Error

Signature: *[static,const]* Severity **Error**

Description: Specifies error severity (preferred action is stop)

Python specific notes:

	The object exposes a readable attribute 'Error'. This is the getter.
Info	**Signature**: *[static,const]* Severity **Info** **Description**: Specifies info severity (print if requested, otherwise silent) **Python specific notes:** The object exposes a readable attribute 'Info'. This is the getter.
NoSeverity	**Signature**: *[static,const]* Severity **NoSeverity** **Description**: Specifies no particular severity (default) **Python specific notes:** The object exposes a readable attribute 'NoSeverity'. This is the getter.
Warning	**Signature**: *[static,const]* Severity **Warning** **Description**: Specifies warning severity (log with high priority, but do not stop) **Python specific notes:** The object exposes a readable attribute 'Warning'. This is the getter.
_create	**Signature**: void **_create** **Description**: Ensures the C++ object is created Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
_destroy	**Signature**: void **_destroy** **Description**: Explicitly destroys the object Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
_destroyed?	**Signature**: *[const]* bool **_destroyed?** **Description**: Returns a value indicating whether the object was already destroyed This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
_is_const_object?	**Signature**: *[const]* bool **_is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference This method returns true, if self is a const reference. In that case, only const methods may be called on self.
_manage	**Signature**: void **_manage** **Description**: Marks the object as managed by the script side. After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required. Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

begin_circuit

Signature: *[virtual]* void **begin_circuit** (const Circuit ptr a, const Circuit ptr b)

Description: This function is called when a new circuit is compared.

This compare procedure will run the netlist compare circuit vs. circuit in a bottom-up fashion. Before each circuit is compared, this method is called once with the circuits that are about to be compared. After the circuit has been compared, end_circuit will be called.

In some cases, the compare algorithm will decide that circuits can't be compared. This happens if for some or all subcircuits the pin assignment can't be derived. In this case, circuit_skipped will be called once instead of begin_circuit and end_circuit.

begin_netlist

Signature: *[virtual]* void **begin_netlist** (const Netlist ptr a, const Netlist ptr b)

Description: This function is called at the beginning of the compare process.

This method is called once when the compare run begins.

circuit_mismatch

Signature: *[virtual]* void **circuit_mismatch** (const Circuit ptr a, const Circuit ptr b, string msg)

Description: This function is called when circuits can't be compared.

This method is called when a circuit can't be mapped to a partner in the other netlist. In this case, this method is called with the one circuit and nil for the other circuit.

This method is called instead of begin_circuit and end_circuit.

circuit_skipped

Signature: *[virtual]* void **circuit_skipped** (const Circuit ptr a, const Circuit ptr b, string msg)

Description: This function is called when circuits can't be compared.

If there is a known circuit pair, but the circuits can be compared - for example because subcircuits can't be identified - this method will be called with both circuits.

This method is called instead of begin_circuit and end_circuit.

device_class_mismatch

Signature: *[virtual]* void **device_class_mismatch** (const DeviceClass ptr a, const DeviceClass ptr b, string msg)

Description: This function is called when device classes can't be compared.

This method is called when a device class can't be mapped to a partner in the other netlist. In this case, this method is called with the one device class and nil for the other class.

device_mismatch

Signature: *[virtual]* void **device_mismatch** (const Device ptr a, const Device ptr b, string msg)

Description: This function is called when two devices can't be paired.

This will report the device considered in a or b. The other argument is nil. See match_devices for details.

end_circuit

Signature: *[virtual]* void **end_circuit** (const Circuit ptr a, const Circuit ptr b, bool matching, string msg)

Description: This function is called at the end of the compare process.

The 'matching' argument indicates whether the circuits have been identified as identical. See begin_circuit for details.

end_netlist

Signature: *[virtual]* void **end_netlist** (const Netlist ptr a, const Netlist ptr b)

Description: This function is called at the end of the compare process.

This method is called once when the compare run ended.

log_entry

Signature: *[virtual]* void **log_entry** (Severity level, string msg)

Description: Issues an entry for the compare log.

This method delivers a log message generated during the compare of two circuits. It is called between of begin_circuit and end_circuit.

This method has been added in version 0.28.

match_ambiguous_nets

Signature: *[virtual]* void **match_ambiguous_nets** (const Net ptr a, const Net ptr b, string msg)

Description: This function is called when two nets are identified, but this choice is ambiguous.

This choice is a last-resort fallback to allow continuation of the compare procedure. It is likely that this compare will fail later. Looking for ambiguous nets allows deduction of the origin of this faulty decision. See match_nets for more details.

match_devices

Signature: *[virtual]* void **match_devices** (const Device ptr a, const Device ptr b)

Description: This function is called when two devices are identified.

If two devices are identified as a corresponding pair, this method will be called with both devices. If the devices can be paired, but the device parameters don't match, match_devices_with_different_parameters will be called instead. If the devices can be paired, but the device classes don't match, match_devices_with_different_device_classes will be called instead. If devices can't be matched, device_mismatch will be called with the one device considered and the other device being nil.

match_devices_with_different_device_classes

Signature: *[virtual]* void **match_devices_with_different_device_classes** (const Device ptr a, const Device ptr b)

Description: This function is called when two devices are identified but have different device classes.

See match_devices for details.

match_devices_with_differer

Signature: *[virtual]* void **match_devices_with_different_parameters** (const Device ptr a, const Device ptr b)

Description: This function is called when two devices are identified but have different parameters.

See match_devices for details.

match_nets

Signature: *[virtual]* void **match_nets** (const Net ptr a, const Net ptr b)

Description: This function is called when two nets are identified.

If two nets are identified as a corresponding pair, this method will be called with both nets. If the nets can be paired, but this match is ambiguous, match_ambiguous_nets will be called instead. If nets can't be matched to a partner, net_mismatch will be called.

match_pins	**Signature**: *[virtual]* void **match_pins** (const Pin ptr a, const Pin ptr b) **Description**: This function is called when two pins are identified. If two pins are identified as a corresponding pair, this method will be called with both pins. If pins can't be matched, pin_mismatch will be called with the one pin considered and the other pin being nil.
match_subcircuits	**Signature**: *[virtual]* void **match_subcircuits** (const SubCircuit ptr a, const SubCircuit ptr b) **Description**: This function is called when two subcircuits are identified. If two subcircuits are identified as a corresponding pair, this method will be called with both subcircuits. If subcircuits can't be matched, subcircuit_mismatch will be called with the one subcircuit considered and the other subcircuit being nil.
net_mismatch	**Signature**: *[virtual]* void **net_mismatch** (const Net ptr a, const Net ptr b, string msg) **Description**: This function is called when a net can't be paired. This method will be called, if a net cannot be identified as identical with another net. The corresponding argument will identify the net and source netlist. The other argument will be nil. In some cases, a mismatch is reported with two nets given. This means, nets are known not to match. Still the compare algorithm will proceed as if these nets were equivalent to derive further matches.
pin_mismatch	**Signature**: *[virtual]* void **pin_mismatch** (const Pin ptr a, const Pin ptr b, string msg) **Description**: This function is called when two pins can't be paired. This will report the pin considered in a or b. The other argument is nil. See match_pins for details.
subcircuit_mismatch	**Signature**: *[virtual]* void **subcircuit_mismatch** (const SubCircuit ptr a, const SubCircuit ptr b, string msg) **Description**: This function is called when two subcircuits can't be paired. This will report the subcircuit considered in a or b. The other argument is nil. See match_subcircuits for details.

4.172. API reference - Class NetlistComparer

Notation used in Ruby API documentation

Module: db

Description: Compares two netlists

This class performs a comparison of two netlists. It can be used with an event receiver (logger) to track the errors and net mismatches. Event receivers are derived from class GenericNetlistCompareLogger. The netlist comparer can be configured in different ways. Specific hints can be given for nets, device classes or circuits to improve efficiency and reliability of the graph equivalence deduction algorithm. For example, objects can be marked as equivalent using same_nets, same_circuits etc. The compare algorithm will then use these hints to derive further equivalences. This way, ambiguities can be resolved.

Another configuration option relates to swappable pins of subcircuits. If pins are marked this way, the compare algorithm may swap them to achieve net matching. Swappable pins belong to an 'equivalence group' and can be defined with equivalent_pins.

This class has been introduced in version 0.26.

Public constructors

new NetlistComparer ptr	**new**		Creates a new comparer object.
new NetlistComparer ptr	**new**	(GenericNetlistCompareLogger ptr logger)	Creates a new comparer object.

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	bool	**compare**	(const Netlist ptr netlist_a, const Netlist ptr netlist_b)	Compares two netlists.
[const]	bool	**compare**	(const Netlist ptr netlist_a, const Netlist ptr netlist_b, NetlistCompareLogger ptr logger)	Compares two netlists.
[const]	bool	**dont_consider_net_nar**		Gets a value indicating whether net names shall not be considered
	void	**dont_consider_net_names=**	(bool f)	Sets a value indicating whether net names shall not be considered
	void	**equivalent_pins**	(const Circuit ptr circuit_b,	Marks two pins of the given circuit as equivalent (i.e. they can be swapped).

			unsigned long pin_id1, unsigned long pin_id2)	
	void	equivalent_pins	(const Circuit ptr circuit_b, unsigned long[] pin_ids)	Marks several pins of the given circuit as equivalent (i.e. they can be swapped).
	void	join_symmetric_nets	(Circuit ptr circuit)	Joins symmetric nodes in the given circuit.
[const]	unsigned long	max_branch_complexity		Gets the maximum branch complexity
	void	max_branch_complexit	(unsigned long n)	Sets the maximum branch complexity
[const]	unsigned long	max_depth		Gets the maximum search depth
	void	max_depth=	(unsigned long n)	Sets the maximum search depth
	void	max_resistance=	(double threshold)	Excludes all resistor devices with a resistance values higher than the given threshold.
	void	min_capacitance=	(double threshold)	Excludes all capacitor devices with a capacitance values less than the given threshold.
	void	same_circuits	(const Circuit ptr circuit_a, const Circuit ptr circuit_b)	Marks two circuits as identical.
	void	same_device_classes	(const DeviceClass ptr dev_cls_a, const DeviceClass ptr dev_cls_b)	Marks two device classes as identical.
	void	same_nets	(const Net ptr net_a, const Net ptr net_b, bool must_match = false)	Marks two nets as identical.
	void	same_nets	(const Circuit ptr circuit_a, const Circuit ptr circuit_b, const Net ptr net_a, const Net ptr net_b, bool must_match = false)	Marks two nets as identical.
[const]	Circuit ptr[]	unmatched_circuits_a	(Netlist ptr a, Netlist ptr b)	Returns a list of circuits in A for which there is not corresponding circuit in B
[const]	Circuit ptr[]	unmatched_circuits_b	(Netlist ptr a, Netlist ptr b)	Returns a list of circuits in B for which there is not corresponding circuit in A
[const]	bool	with_log		Gets a value indicating that log messages are generated.
	void	with_log=	(bool flag)	Sets a value indicating that log messages are generated.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method

will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

compare

(1) Signature: *[const]* bool **compare** (const Netlist ptr netlist_a, const Netlist ptr netlist_b)

Description: Compares two netlists.

This method will perform the actual netlist compare. It will return true if both netlists are identical. If the comparer has been configured with same_nets or similar methods, the objects given there must be located inside 'circuit_a' and 'circuit_b' respectively.

(2) Signature: *[const]* bool **compare** (const Netlist ptr netlist_a, const Netlist ptr netlist_b, NetlistCompareLogger ptr logger)

Description: Compares two netlists.

This method will perform the actual netlist compare using the given logger. It will return true if both netlists are identical. If the comparer has been configured with same_nets or similar methods, the objects given there must be located inside 'circuit_a' and 'circuit_b' respectively.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dont_consider_net_names

Signature: *[const]* bool **dont_consider_net_names**

Description: Gets a value indicating whether net names shall not be considered

See dont_consider_net_names= for details.

Python specific notes:
The object exposes a readable attribute 'dont_consider_net_names'. This is the getter.

dont_consider_net_names=

Signature: void **dont_consider_net_names=** (bool f)

Description: Sets a value indicating whether net names shall not be considered

If this value is set to true, net names will not be considered when resolving ambiguities. Not considering net names usually is more expensive. The default is 'false' indicating that net names will be considered for ambiguity resolution.

This property has been introduced in version 0.26.7.

Python specific notes:
The object exposes a writable attribute 'dont_consider_net_names'. This is the setter.

equivalent_pins

(1) Signature: void **equivalent_pins** (const Circuit ptr circuit_b, unsigned long pin_id1, unsigned long pin_id2)

Description: Marks two pins of the given circuit as equivalent (i.e. they can be swapped).

Only circuits from the second input can be given swappable pins. This will imply the same swappable pins on the equivalent circuit of the first input. To mark multiple pins as swappable, use the version that takes a list of pins.

(2) Signature: void **equivalent_pins** (const Circuit ptr circuit_b, unsigned long[] pin_ids)

Description: Marks several pins of the given circuit as equivalent (i.e. they can be swapped).

Only circuits from the second input can be given swappable pins. This will imply the same swappable pins on the equivalent circuit of the first input. This version is a generic variant of the two-pin version of this method.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

join_symmetric_nets

Signature: void **join_symmetric_nets** (Circuit ptr circuit)

Description: Joins symmetric nodes in the given circuit.

Nodes are symmetrical if swapping them would not modify the circuit. Hence they will carry the same potential and can be connected (joined). This will simplify the circuit and can be applied before device combination to render a schematic-equivalent netlist in some cases (split gate option).

This algorithm will apply the comparer's settings to the symmetry condition (device filtering, device compare tolerances, device class equivalence etc.).

This method has been introduced in version 0.26.4.

max_branch_complexity

Signature: *[const]* unsigned long **max_branch_complexity**

Description: Gets the maximum branch complexity

See max_branch_complexity= for details.

Python specific notes:
The object exposes a readable attribute 'max_branch_complexity'. This is the getter.

max_branch_complexity=

Signature: void **max_branch_complexity=** (unsigned long n)

Description: Sets the maximum branch complexity

This value limits the maximum branch complexity of the backtracking algorithm. The complexity is the accumulated number of branch options with ambiguous net matches. Backtracking will stop when the maximum number of options has been exceeded.

By default, from version 0.27 on the complexity is unlimited and can be reduced in cases where runtimes need to be limited at the cost less elaborate matching evaluation.

As the computational complexity is the square of the branch count, this value should be adjusted carefully.

Python specific notes:
The object exposes a writable attribute 'max_branch_complexity'. This is the setter.

max_depth

Signature: *[const]* unsigned long **max_depth**

Description: Gets the maximum search depth

See max_depth= for details.

Python specific notes:
The object exposes a readable attribute 'max_depth'. This is the getter.

max_depth=

Signature: void **max_depth=** (unsigned long n)

Description: Sets the maximum search depth

This value limits the search depth of the backtracking algorithm to the given number of jumps.

By default, from version 0.27 on the depth is unlimited and can be reduced in cases where runtimes need to be limited at the cost less elaborate matching evaluation.

Python specific notes:
The object exposes a writable attribute 'max_depth'. This is the setter.

max_resistance=

Signature: void **max_resistance=** (double threshold)

Description: Excludes all resistor devices with a resistance values higher than the given threshold.

To reset this constraint, set this attribute to zero.

Python specific notes:
The object exposes a writable attribute 'max_resistance'. This is the setter.

min_capacitance=

Signature: void **min_capacitance=** (double threshold)

Description: Excludes all capacitor devices with a capacitance values less than the given threshold.

To reset this constraint, set this attribute to zero.

Python specific notes:
The object exposes a writable attribute 'min_capacitance'. This is the setter.

new

(1) Signature: *[static]* new NetlistComparer ptr **new**

Description: Creates a new comparer object.

See the class description for more details.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new NetlistComparer ptr **new** (GenericNetlistCompareLogger ptr logger)

Description: Creates a new comparer object.

The logger is a delegate or event receiver which the comparer will send compare events to. See the class description for more details.

Python specific notes:
This method is the default initializer of the object.

same_circuits

Signature: void **same_circuits** (const Circuit ptr circuit_a, const Circuit ptr circuit_b)

Description: Marks two circuits as identical.

	This method makes a circuit circuit_a in netlist a identical to the corresponding circuit circuit_b in netlist b (see compare). By default circuits with the same name are identical.
same_device_classes	**Signature**: void **same_device_classes** (const DeviceClass ptr dev_cls_a, const DeviceClass ptr dev_cls_b) **Description**: Marks two device classes as identical. This makes a device class dev_cls_a in netlist a identical to the corresponding device class dev_cls_b in netlist b (see compare). By default device classes with the same name are identical.
same_nets	**(1) Signature**: void **same_nets** (const Net ptr net_a, const Net ptr net_b, bool must_match = false) **Description**: Marks two nets as identical. This makes a net net_a in netlist a identical to the corresponding net net_b in netlist b (see compare). Otherwise, the algorithm will try to identify nets according to their topology. This method can be used to supply hints to the compare algorithm. It will use these hints to derive further identities. If 'must_match' is true, the nets are required to match. If they don't, an error is reported. The 'must_match' optional argument has been added in version 0.27.3. **(2) Signature**: void **same_nets** (const Circuit ptr circuit_a, const Circuit ptr circuit_b, const Net ptr net_a, const Net ptr net_b, bool must_match = false) **Description**: Marks two nets as identical. This makes a net net_a in netlist a identical to the corresponding net net_b in netlist b (see compare). Otherwise, the algorithm will try to identify nets according to their topology. This method can be used to supply hints to the compare algorithm. It will use these hints to derive further identities. If 'must_match' is true, the nets are required to match. If they don't, an error is reported. This variant allows specifying nil for the nets indicating the nets are mismatched by definition. with 'must_match' this will render a net mismatch error. This variant has been added in version 0.27.3.
unmatched_circuits_a	**Signature**: *[const]* Circuit ptr[] **unmatched_circuits_a** (Netlist ptr a, Netlist ptr b) **Description**: Returns a list of circuits in A for which there is not corresponding circuit in B This list can be used to flatten these circuits so they do not participate in the compare process.
unmatched_circuits_b	**Signature**: *[const]* Circuit ptr[] **unmatched_circuits_b** (Netlist ptr a, Netlist ptr b) **Description**: Returns a list of circuits in B for which there is not corresponding circuit in A This list can be used to flatten these circuits so they do not participate in the compare process.
with_log	**Signature**: *[const]* bool **with_log** **Description**: Gets a value indicating that log messages are generated. See with_log= for details about this flag. This attribute have been introduced in version 0.28. **Python specific notes:** The object exposes a readable attribute 'with_log'. This is the getter.
with_log=	**Signature**: void **with_log=** (bool flag)

Description: Sets a value indicating that log messages are generated.

Log messages may be expensive to compute, hence they can be turned off. By default, log messages are generated.

This attribute have been introduced in version 0.28.

Python specific notes:
The object exposes a writable attribute 'with_log'. This is the setter.

4.173. API reference - Class NetlistCrossReference

Notation used in Ruby API documentation

Module: db

Description: Represents the identity mapping between the objects of two netlists.

Class hierarchy: NetlistCrossReference » NetlistCompareLogger

Sub-classes: NetPairData, DevicePairData, PinPairData, SubCircuitPairData, CircuitPairData, NetTerminalRefPair, NetPinRefPair, NetSubcircuitPinRefPair, Status

The NetlistCrossReference object is a container for the results of a netlist comparison. It implemented the NetlistCompareLogger interface, hence can be used as output for a netlist compare operation (NetlistComparer#compare). It's purpose is to store the results of the compare. It is used in this sense inside the LayoutVsSchematic framework.

The basic idea of the cross reference object is pairing: the netlist comparer will try to identify matching items and store them as pairs inside the cross reference object. If no match is found, a single-sided pair is generated: one item is nil in this case. Beside the items, a status is kept which gives more details about success or failure of the match operation.

Item pairing happens on different levels, reflecting the hierarchy of the netlists. On the top level there are circuits. Inside circuits nets, devices, subcircuits and pins are paired. Nets further contribute their connected items through terminals (for devices), pins (outgoing) and subcircuit pins.

This class has been introduced in version 0.26.

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	unsigned long	**circuit_count**		Gets the number of circuit pairs in the cross-reference object.
[iter]	NetlistCrossReference::CircuitPairData	**each_circuit_pair**		Delivers the circuit pairs and their status.
[iter]	NetlistCrossReference::De	**each_device_pair**	(const NetlistCrossReference circuit_pair)	Delivers the device pairs and their status for the given circuit pair.
[iter]	NetlistCrossReference::NetPairData	**each_net_pair**	(const NetlistCrossReference::CircuitPairData circuit_pair)	Delivers the net pairs and their status for the given circuit pair.
[iter]	NetlistCrossReference::Ne	**each_net_pin_pair**	(const NetlistCrossReference net_pair)	Delivers the pin pairs for the given net pair.

[iter]	NetlistCrossReference::NetSubcircuitPinPairOfCircuit	**each_net_subcircuit_pin_pair**	(const NetlistCrossReference::NetPinPair net_pair)	Delivers the subcircuit pin pairs for the given net pair.
[iter]	NetlistCrossReference::Ne	**each_net_terminal_pa**	(const NetlistCrossReference net_pair)	Delivers the device terminal pairs for the given net pair.
[iter]	NetlistCrossReference::PinPairData	**each_pin_pair**	(const NetlistCrossReference::Circuit circuit_pair)	Delivers the pin pairs and their status for the given circuit pair.
[iter]	NetlistCrossReference::Su	**each_subcircuit_pair**	(const NetlistCrossReference circuit_pair)	Delivers the subcircuit pairs and their status for the given circuit pair.
[const]	const Netlist ptr	**netlist_a**		Gets the first netlist which participated in the compare.
[const]	const Netlist ptr	**netlist_b**		Gets the second netlist which participated in the compare.
[const]	const Circuit ptr	**other_circuit_for**	(const Circuit ptr circuit)	Gets the matching other circuit for a given primary circuit.
[const]	const Device ptr	**other_device_for**	(const Device ptr device)	Gets the matching other device for a given primary device.
[const]	const Net ptr	**other_net_for**	(const Net ptr net)	Gets the matching other net for a given primary net.
[const]	const Pin ptr	**other_pin_for**	(const Pin ptr pin)	Gets the matching other pin for a given primary pin.
[const]	const SubCircuit ptr	**other_subcircuit_for**	(const SubCircuit ptr subcircuit)	Gets the matching other subcircuit for a given primary subcircuit.

Public static methods and constants

[static,const]	NetlistCrossReference::Status	**Match**	Enum constant NetlistCrossReference::Match
[static,const]	NetlistCrossReference::Status	**MatchWithWarning**	Enum constant NetlistCrossReference::MatchWithWarning
[static,const]	NetlistCrossReference::Status	**Mismatch**	Enum constant NetlistCrossReference::Mismatch
[static,const]	NetlistCrossReference::Status	**NoMatch**	Enum constant NetlistCrossReference::NoMatch
[static,const]	NetlistCrossReference::Status	**None**	Enum constant NetlistCrossReference::None
[static,const]	NetlistCrossReference::Status	**Skipped**	Enum constant NetlistCrossReference::Skipped

Detailed description

Match

Signature: *[static,const]* NetlistCrossReference::Status **Match**

Description: Enum constant NetlistCrossReference::Match

An exact match exists if this code is present.

Python specific notes:
The object exposes a readable attribute 'Match'. This is the getter.

MatchWithWarning

Signature: *[static,const]* NetlistCrossReference::Status **MatchWithWarning**

Description: Enum constant NetlistCrossReference::MatchWithWarning

If this code is present, a match was found but a warning is issued. For nets, this means that the choice is ambiguous and one, unspecific candidate has been chosen. For devices, this means a device match was established, but parameters or the device class are not matching exactly.

Python specific notes:
The object exposes a readable attribute 'MatchWithWarning'. This is the getter.

Mismatch

Signature: *[static,const]* NetlistCrossReference::Status **Mismatch**

Description: Enum constant NetlistCrossReference::Mismatch

This code means there is a match candidate, but exact identity could not be confirmed.

Python specific notes:
The object exposes a readable attribute 'Mismatch'. This is the getter.

NoMatch

Signature: *[static,const]* NetlistCrossReference::Status **NoMatch**

Description: Enum constant NetlistCrossReference::NoMatch

If this code is present, no match could be found. There is also 'Mismatch' which means there is a candidate, but exact identity could not be confirmed.

Python specific notes:
The object exposes a readable attribute 'NoMatch'. This is the getter.

None

Signature: *[static,const]* NetlistCrossReference::Status **None**

Description: Enum constant NetlistCrossReference::None

No specific status is implied if this code is present.

Python specific notes:
This member is available as 'None_' in Python.
The object exposes a readable attribute 'None_'. This is the getter.

Skipped

Signature: *[static,const]* NetlistCrossReference::Status **Skipped**

Description: Enum constant NetlistCrossReference::Skipped

On circuits this code means that a match has not been attempted because subcircuits of this circuits were not matched. As circuit matching happens bottom-up, all subcircuits must match at least with respect to their pins to allow any parent circuit to be matched.

Python specific notes:
The object exposes a readable attribute 'Skipped'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

circuit_count

Signature: *[const]* unsigned long **circuit_count**

Description: Gets the number of circuit pairs in the cross-reference object.

each_circuit_pair

Signature: *[iter]* NetlistCrossReference::CircuitPairData **each_circuit_pair**

Description: Delivers the circuit pairs and their status.

See the class description for details.

each_device_pair

Signature: *[iter]* NetlistCrossReference::DevicePairData **each_device_pair** (const NetlistCrossReference::CircuitPairData circuit_pair)

Description: Delivers the device pairs and their status for the given circuit pair.

	See the class description for details.
each_net_pair	**Signature**: *[iter]* NetlistCrossReference::NetPairData **each_net_pair** (const NetlistCrossReference::CircuitPairData circuit_pair) **Description**: Delivers the net pairs and their status for the given circuit pair. See the class description for details.
each_net_pin_pair	**Signature**: *[iter]* NetlistCrossReference::NetPinRefPair **each_net_pin_pair** (const NetlistCrossReference::NetPairData net_pair) **Description**: Delivers the pin pairs for the given net pair. For the net pair, lists the pin pairs identified on this net.
each_net_subcircuit_pin_pair	**Signature**: *[iter]* NetlistCrossReference::NetSubcircuitPinRefPair **each_net_subcircuit_pin_pair** (const NetlistCrossReference::NetPairData net_pair) **Description**: Delivers the subcircuit pin pairs for the given net pair. For the net pair, lists the subcircuit pin pairs identified on this net.
each_net_terminal_pair	**Signature**: *[iter]* NetlistCrossReference::NetTerminalRefPair **each_net_terminal_pair** (const NetlistCrossReference::NetPairData net_pair) **Description**: Delivers the device terminal pairs for the given net pair. For the net pair, lists the device terminal pairs identified on this net.
each_pin_pair	**Signature**: *[iter]* NetlistCrossReference::PinPairData **each_pin_pair** (const NetlistCrossReference::CircuitPairData circuit_pair) **Description**: Delivers the pin pairs and their status for the given circuit pair. See the class description for details.
each_subcircuit_pair	**Signature**: *[iter]* NetlistCrossReference::SubCircuitPairData **each_subcircuit_pair** (const NetlistCrossReference::CircuitPairData circuit_pair) **Description**: Delivers the subcircuit pairs and their status for the given circuit pair. See the class description for details.
netlist_a	**Signature**: *[const]* const Netlist ptr **netlist_a** **Description**: Gets the first netlist which participated in the compare. This member may be nil, if the respective netlist is no longer valid. In this case, the netlist cross-reference object cannot be used.
netlist_b	**Signature**: *[const]* const Netlist ptr **netlist_b** **Description**: Gets the second netlist which participated in the compare. This member may be nil, if the respective netlist is no longer valid.In this case, the netlist cross-reference object cannot be used.
other_circuit_for	**Signature**: *[const]* const Circuit ptr **other_circuit_for** (const Circuit ptr circuit) **Description**: Gets the matching other circuit for a given primary circuit. The return value will be nil if no match is found. Otherwise it is the 'b' circuit for circuits from the 'a' netlist and vice versa.

	This method has been introduced in version 0.27.
other_device_for	**Signature**: *[const]* const Device ptr **other_device_for** (const Device ptr device) **Description**: Gets the matching other device for a given primary device. The return value will be nil if no match is found. Otherwise it is the 'b' device for devices from the 'a' netlist and vice versa. This method has been introduced in version 0.27.
other_net_for	**Signature**: *[const]* const Net ptr **other_net_for** (const Net ptr net) **Description**: Gets the matching other net for a given primary net. The return value will be nil if no match is found. Otherwise it is the 'b' net for nets from the 'a' netlist and vice versa.
other_pin_for	**Signature**: *[const]* const Pin ptr **other_pin_for** (const Pin ptr pin) **Description**: Gets the matching other pin for a given primary pin. The return value will be nil if no match is found. Otherwise it is the 'b' pin for pins from the 'a' netlist and vice versa. This method has been introduced in version 0.27.
other_subcircuit_for	**Signature**: *[const]* const SubCircuit ptr **other_subcircuit_for** (const SubCircuit ptr subcircuit) **Description**: Gets the matching other subcircuit for a given primary subcircuit. The return value will be nil if no match is found. Otherwise it is the 'b' subcircuit for subcircuits from the 'a' netlist and vice versa. This method has been introduced in version 0.27.

4.174. API reference - Class NetlistCrossReference::NetPairData

Notation used in Ruby API documentation

Module: db

Description: A net match entry.

This class is equivalent to the class NetlistCrossReference::NetPairData

This object is used to describe the relationship of two nets in a netlist match.

Upon successful match, the first and second members are the matching objects and status is 'Match'. This object is also used to describe non-matches or match errors. In this case, first or second may be nil and status further describes the case.

Public methods

[const]	const Net ptr	**first**	Gets the first object of the relation pair.
[const]	const Net ptr	**second**	Gets the second object of the relation pair.
[const]	NetlistCrossReference::Status	**status**	Gets the status of the relation.

Detailed description

first

Signature: *[const]* const Net ptr **first**

Description: Gets the first object of the relation pair.

The first object is usually the one obtained from the layout-derived netlist. This member can be nil if the pair is describing a non-matching reference object. In this case, the second member is the reference object for which no match was found.

second

Signature: *[const]* const Net ptr **second**

Description: Gets the second object of the relation pair.

The first object is usually the one obtained from the reference netlist. This member can be nil if the pair is describing a non-matching layout object. In this case, the first member is the layout-derived object for which no match was found.

status

Signature: *[const]* NetlistCrossReference::Status **status**

Description: Gets the status of the relation.

This enum described the match status of the relation pair.

4.175. API reference - Class NetlistCrossReference::DevicePairData

Notation used in Ruby API documentation

Module: db

Description: A device match entry.

This class is equivalent to the class NetlistCrossReference::DevicePairData

This object is used to describe the relationship of two devices in a netlist match.

Upon successful match, the first and second members are the matching objects and status is 'Match'. This object is also used to describe non-matches or match errors. In this case, first or second may be nil and status further describes the case.

Public methods

[const]	const Device ptr	**first**	Gets the first object of the relation pair.
[const]	const Device ptr	**second**	Gets the second object of the relation pair.
[const]	NetlistCrossReference::Status	**status**	Gets the status of the relation.

Detailed description

first

Signature: *[const]* const Device ptr **first**

Description: Gets the first object of the relation pair.

The first object is usually the one obtained from the layout-derived netlist. This member can be nil if the pair is describing a non-matching reference object. In this case, the second member is the reference object for which no match was found.

second

Signature: *[const]* const Device ptr **second**

Description: Gets the second object of the relation pair.

The first object is usually the one obtained from the reference netlist. This member can be nil if the pair is describing a non-matching layout object. In this case, the first member is the layout-derived object for which no match was found.

status

Signature: *[const]* NetlistCrossReference::Status **status**

Description: Gets the status of the relation.

This enum described the match status of the relation pair.

4.176. API reference - Class NetlistCrossReference::PinPairData

Notation used in Ruby API documentation

Module: db

Description: A pin match entry.

This class is equivalent to the class NetlistCrossReference::PinPairData

This object is used to describe the relationship of two circuit pins in a netlist match.

Upon successful match, the first and second members are the matching objects and status is 'Match'. This object is also used to describe non-matches or match errors. In this case, first or second may be nil and status further describes the case.

Public methods

[const]	const Pin ptr	**first**	Gets the first object of the relation pair.
[const]	const Pin ptr	**second**	Gets the second object of the relation pair.
[const]	NetlistCrossReference::Status	**status**	Gets the status of the relation.

Detailed description

first

Signature: *[const]* const Pin ptr **first**

Description: Gets the first object of the relation pair.

The first object is usually the one obtained from the layout-derived netlist. This member can be nil if the pair is describing a non-matching reference object. In this case, the second member is the reference object for which no match was found.

second

Signature: *[const]* const Pin ptr **second**

Description: Gets the second object of the relation pair.

The first object is usually the one obtained from the reference netlist. This member can be nil if the pair is describing a non-matching layout object. In this case, the first member is the layout-derived object for which no match was found.

status

Signature: *[const]* NetlistCrossReference::Status **status**

Description: Gets the status of the relation.

This enum described the match status of the relation pair.

4.177. API reference - Class NetlistCrossReference::SubCircuitPairData

Notation used in Ruby API documentation

Module: db

Description: A subcircuit match entry.

This class is equivalent to the class NetlistCrossReference::SubCircuitPairData

This object is used to describe the relationship of two subcircuits in a netlist match.

Upon successful match, the first and second members are the matching objects and status is 'Match'. This object is also used to describe non-matches or match errors. In this case, first or second may be nil and status further describes the case.

Public methods

[const]	const SubCircuit ptr	**first**	Gets the first object of the relation pair.
[const]	const SubCircuit ptr	**second**	Gets the second object of the relation pair.
[const]	NetlistCrossReference::Status	**status**	Gets the status of the relation.

Detailed description

first

Signature: *[const]* const SubCircuit ptr **first**

Description: Gets the first object of the relation pair.

The first object is usually the one obtained from the layout-derived netlist. This member can be nil if the pair is describing a non-matching reference object. In this case, the second member is the reference object for which no match was found.

second

Signature: *[const]* const SubCircuit ptr **second**

Description: Gets the second object of the relation pair.

The first object is usually the one obtained from the reference netlist. This member can be nil if the pair is describing a non-matching layout object. In this case, the first member is the layout-derived object for which no match was found.

status

Signature: *[const]* NetlistCrossReference::Status **status**

Description: Gets the status of the relation.

This enum described the match status of the relation pair.

4.178. API reference - Class NetlistCrossReference::CircuitPairData

Notation used in Ruby API documentation

Module: db

Description: A circuit match entry.

This class is equivalent to the class NetlistCrossReference::CircuitPairData

This object is used to describe the relationship of two circuits in a netlist match.

Upon successful match, the first and second members are the matching objects and status is 'Match'. This object is also used to describe non-matches or match errors. In this case, first or second may be nil and status further describes the case.

Public methods

[const]	const Circuit ptr	**first**	Gets the first object of the relation pair.
[const]	const Circuit ptr	**second**	Gets the second object of the relation pair.
[const]	NetlistCrossReference::Status	**status**	Gets the status of the relation.

Detailed description

first

Signature: *[const]* const Circuit ptr **first**

Description: Gets the first object of the relation pair.

The first object is usually the one obtained from the layout-derived netlist. This member can be nil if the pair is describing a non-matching reference object. In this case, the second member is the reference object for which no match was found.

second

Signature: *[const]* const Circuit ptr **second**

Description: Gets the second object of the relation pair.

The first object is usually the one obtained from the reference netlist. This member can be nil if the pair is describing a non-matching layout object. In this case, the first member is the layout-derived object for which no match was found.

status

Signature: *[const]* NetlistCrossReference::Status **status**

Description: Gets the status of the relation.

This enum described the match status of the relation pair.

4.179. API reference - Class NetlistCrossReference::NetTerminalRefPair

Notation used in Ruby API documentation

Module: db

Description: A match entry for a net terminal pair.

This class is equivalent to the class NetlistCrossReference::NetTerminalRefPair

This object is used to describe the matching terminal pairs or non-matching terminals on a net.

Upon successful match, the first and second members are the matching net objects.Otherwise, either first or second is nil and the other member is the object for which no match was found.

Public methods

[const]	const NetTerminalRef ptr	**first**	Gets the first object of the relation pair.
[const]	const NetTerminalRef ptr	**second**	Gets the second object of the relation pair.

Detailed description

first

Signature: *[const]* const NetTerminalRef ptr **first**

Description: Gets the first object of the relation pair.

The first object is usually the one obtained from the layout-derived netlist. This member can be nil if the pair is describing a non-matching reference object. In this case, the second member is the reference object for which no match was found.

second

Signature: *[const]* const NetTerminalRef ptr **second**

Description: Gets the second object of the relation pair.

The first object is usually the one obtained from the reference netlist. This member can be nil if the pair is describing a non-matching layout object. In this case, the first member is the layout-derived object for which no match was found.

4.180. API reference - Class NetlistCrossReference::NetPinRefPair

Notation used in Ruby API documentation

Module: db

Description: A match entry for a net pin pair.

This class is equivalent to the class NetlistCrossReference::NetPinRefPair

This object is used to describe the matching pin pairs or non-matching pins on a net.

Upon successful match, the first and second members are the matching net objects.Otherwise, either first or second is nil and the other member is the object for which no match was found.

Public methods

[const]	const NetPinRef ptr	**first**	Gets the first object of the relation pair.
[const]	const NetPinRef ptr	**second**	Gets the second object of the relation pair.

Detailed description

first

Signature: *[const]* const NetPinRef ptr **first**

Description: Gets the first object of the relation pair.

The first object is usually the one obtained from the layout-derived netlist. This member can be nil if the pair is describing a non-matching reference object. In this case, the second member is the reference object for which no match was found.

second

Signature: *[const]* const NetPinRef ptr **second**

Description: Gets the second object of the relation pair.

The first object is usually the one obtained from the reference netlist. This member can be nil if the pair is describing a non-matching layout object. In this case, the first member is the layout-derived object for which no match was found.

4.181. API reference - Class NetlistCrossReference::NetSubcircuitPinRefPair

Notation used in Ruby API documentation

Module: db

Description: A match entry for a net subcircuit pin pair.

This class is equivalent to the class NetlistCrossReference::NetSubcircuitPinRefPair

This object is used to describe the matching subcircuit pin pairs or non-matching subcircuit pins on a net.

Upon successful match, the first and second members are the matching net objects.Otherwise, either first or second is nil and the other member is the object for which no match was found.

Public methods

[const]	const NetSubcircuitPinRef ptr	**first**	Gets the first object of the relation pair.
[const]	const NetSubcircuitPinRef ptr	**second**	Gets the second object of the relation pair.

Detailed description

first

Signature: *[const]* const NetSubcircuitPinRef ptr **first**

Description: Gets the first object of the relation pair.

The first object is usually the one obtained from the layout-derived netlist. This member can be nil if the pair is describing a non-matching reference object. In this case, the second member is the reference object for which no match was found.

second

Signature: *[const]* const NetSubcircuitPinRef ptr **second**

Description: Gets the second object of the relation pair.

The first object is usually the one obtained from the reference netlist. This member can be nil if the pair is describing a non-matching layout object. In this case, the first member is the layout-derived object for which no match was found.

4.182. API reference - Class NetlistCrossReference::Status

Notation used in Ruby API documentation

Module: db

Description: This class represents the NetlistCrossReference::Status enum

This class is equivalent to the class NetlistCrossReference::Status

Public constructors

new NetlistCrossReference::Status ptr	**new**	(int i)	Creates an enum from an integer value
new NetlistCrossReference::Status ptr	**new**	(string s)	Creates an enum from a string value

Public methods

[const]	bool	**!=**	(const NetlistCrossReference::S other)	Compares two enums for inequality
[const]	bool	**!=**	(int other)	Compares an enum with an integer for inequality
[const]	bool	**<**	(const NetlistCrossReference::S other)	Returns true if the first enum is less (in the enum symbol order) than the second
[const]	bool	**<**	(int other)	Returns true if the enum is less (in the enum symbol order) than the integer value
[const]	bool	**==**	(const NetlistCrossReference::S other)	Compares two enums
[const]	bool	**==**	(int other)	Compares an enum with an integer value
[const]	int	**hash**		Gets the hash value from the enum
[const]	string	**inspect**		Converts an enum to a visual string
[const]	int	**to_i**		Gets the integer value from the enum
[const]	string	**to_s**		Gets the symbolic string from an enum

Public static methods and constants

[static,const]	NetlistCrossReference::Status	**Match**	Enum constant NetlistCrossReference::Match
[static,const]	NetlistCrossReference::Status	**MatchWithWarning**	Enum constant NetlistCrossReference::MatchWithWarning
[static,const]	NetlistCrossReference::Status	**Mismatch**	Enum constant NetlistCrossReference::Mismatch

[static,const]	NetlistCrossReference::Status	**NoMatch**	Enum constant NetlistCrossReference::NoMatch
[static,const]	NetlistCrossReference::Status	**None**	Enum constant NetlistCrossReference::None
[static,const]	NetlistCrossReference::Status	**Skipped**	Enum constant NetlistCrossReference::Skipped

Detailed description

!=	**(1) Signature**: *[const]* bool **!=** (const NetlistCrossReference::Status other) **Description**: Compares two enums for inequality **(2) Signature**: *[const]* bool **!=** (int other) **Description**: Compares an enum with an integer for inequality
<	**(1) Signature**: *[const]* bool **<** (const NetlistCrossReference::Status other) **Description**: Returns true if the first enum is less (in the enum symbol order) than the second **(2) Signature**: *[const]* bool **<** (int other) **Description**: Returns true if the enum is less (in the enum symbol order) than the integer value
==	**(1) Signature**: *[const]* bool **==** (const NetlistCrossReference::Status other) **Description**: Compares two enums **(2) Signature**: *[const]* bool **==** (int other) **Description**: Compares an enum with an integer value
Match	**Signature**: *[static,const]* NetlistCrossReference::Status **Match** **Description**: Enum constant NetlistCrossReference::Match An exact match exists if this code is present. **Python specific notes:** The object exposes a readable attribute 'Match'. This is the getter.
MatchWithWarning	**Signature**: *[static,const]* NetlistCrossReference::Status **MatchWithWarning** **Description**: Enum constant NetlistCrossReference::MatchWithWarning If this code is present, a match was found but a warning is issued. For nets, this means that the choice is ambiguous and one, unspecific candidate has been chosen. For devices, this means a device match was established, but parameters or the device class are not matching exactly. **Python specific notes:** The object exposes a readable attribute 'MatchWithWarning'. This is the getter.
Mismatch	**Signature**: *[static,const]* NetlistCrossReference::Status **Mismatch** **Description**: Enum constant NetlistCrossReference::Mismatch This code means there is a match candidate, but exact identity could not be confirmed. **Python specific notes:**

The object exposes a readable attribute 'Mismatch'. This is the getter.

NoMatch

Signature: *[static,const]* NetlistCrossReference::Status **NoMatch**

Description: Enum constant NetlistCrossReference::NoMatch

If this code is present, no match could be found. There is also 'Mismatch' which means there is a candidate, but exact identity could not be confirmed.

Python specific notes:
The object exposes a readable attribute 'NoMatch'. This is the getter.

None

Signature: *[static,const]* NetlistCrossReference::Status **None**

Description: Enum constant NetlistCrossReference::None

No specific status is implied if this code is present.

Python specific notes:
This member is available as 'None_' in Python.
The object exposes a readable attribute 'None_'. This is the getter.

Skipped

Signature: *[static,const]* NetlistCrossReference::Status **Skipped**

Description: Enum constant NetlistCrossReference::Skipped

On circuits this code means that a match has not been attempted because subcircuits of this circuits were not matched. As circuit matching happens bottom-up, all subcircuits must match at least with respect to their pins to allow any parent circuit to be matched.

Python specific notes:
The object exposes a readable attribute 'Skipped'. This is the getter.

hash

Signature: *[const]* int **hash**

Description: Gets the hash value from the enum

Python specific notes:
This method is also available as 'hash(object)'.

inspect

Signature: *[const]* string **inspect**

Description: Converts an enum to a visual string

Python specific notes:
This method is also available as 'repr(object)'.

new

(1) Signature: *[static]* new NetlistCrossReference::Status ptr **new** (int i)

Description: Creates an enum from an integer value

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new NetlistCrossReference::Status ptr **new** (string s)

Description: Creates an enum from a string value

Python specific notes:
This method is the default initializer of the object.

to_i

Signature: *[const]* int **to_i**

Description: Gets the integer value from the enum

Python specific notes:

This method is also available as 'int(object)'.

to_s

Signature: *[const]* string **to_s**

Description: Gets the symbolic string from an enum

Python specific notes:
This method is also available as 'str(object)'.

4.183. API reference - Class LayoutVsSchematic

Notation used in Ruby API documentation

Module: db

Description: A generic framework for doing LVS (layout vs. schematic)

Class hierarchy: LayoutVsSchematic » LayoutToNetlist

This class extends the concept of the netlist extraction from a layout to LVS verification. It does so by adding these concepts to the LayoutToNetlist class:

- A reference netlist. This will be the netlist against which the layout-derived netlist is compared against. See reference and reference=.
- A compare step. During the compare the layout-derived netlist and the reference netlists are compared. The compare results are captured in the cross-reference object. See compare and NetlistComparer for the comparer object.
- A cross-reference. This object (of class NetlistCrossReference) will keep the relations between the objects of the two netlists. It also lists the differences between the netlists. See xref about how to access this object.

The LVS object can be persisted to and from a file in a specific format, so it is sometimes referred to as the "LVS database".

LVS objects can be attached to layout views with LayoutView#add_lvsdb so they become available in the netlist database browser.

This class has been introduced in version 0.26.

Public constructors

new LayoutVsSchematic ptr	**new**	(const RecursiveShapeIterator iter)	Creates a new LVS object with the extractor connected to an original layout
new LayoutVsSchematic ptr	**new**		Creates a new LVS object
new LayoutVsSchematic ptr	**new**	(DeepShapeStore ptr dss)	Creates a new LVS object with the extractor object reusing an existing DeepShapeStore object
new LayoutVsSchematic ptr	**new**	(DeepShapeStore ptr dss, unsigned int layout_index)	Creates a new LVS object with the extractor object reusing an existing DeepShapeStore object
new LayoutVsSchematic ptr	**new**	(string topcell_name, double dbu)	Creates a new LVS object with the extractor object taking a flat DSS

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference
	void	**_manage**	Marks the object as managed by the script side.

void	**_unmanage**		Marks the object as no longer owned by the script side.
bool	**compare**	(NetlistComparer ptr comparer)	Compare the layout-extracted netlist against the reference netlist using the given netlist comparer.
void	**read**	(string path)	Reads the LVS object from the file.
void	**read_l2n**	(string path)	Reads the LayoutToNetlist part of the object from a file.
Netlist ptr	**reference**		Gets the reference netlist.
void	**reference=**	(Netlist ptr reference_netlist)	Sets the reference netlist.
void	**write**	(string path, bool short_format = false)	Writes the LVS object to a file.
void	**write_l2n**	(string path, bool short_format = false)	Writes the LayoutToNetlist part of the object to a file.
NetlistCrossReference ptr	**xref**		Gets the cross-reference object

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

compare

Signature: bool **compare** (NetlistComparer ptr comparer)

Description: Compare the layout-extracted netlist against the reference netlist using the given netlist comparer.

new

(1) Signature: *[static]* new LayoutVsSchematic ptr **new** (const RecursiveShapeIterator iter)

Description: Creates a new LVS object with the extractor connected to an original layout

This constructor will attach the extractor of the LVS object to an original layout through the shape iterator.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new LayoutVsSchematic ptr **new**

Description: Creates a new LVS object

The main objective for this constructor is to create an object suitable for reading and writing LVS database files.

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new LayoutVsSchematic ptr **new** (DeepShapeStore ptr dss)

Description: Creates a new LVS object with the extractor object reusing an existing DeepShapeStore object

See the corresponding constructor of the LayoutToNetlist object for more details.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new LayoutVsSchematic ptr **new** (DeepShapeStore ptr dss, unsigned int layout_index)

Description: Creates a new LVS object with the extractor object reusing an existing DeepShapeStore object

See the corresponding constructor of the LayoutToNetlist object for more details.

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new LayoutVsSchematic ptr **new** (string topcell_name, double dbu)

Description: Creates a new LVS object with the extractor object taking a flat DSS

See the corresponding constructor of the LayoutToNetlist object for more details.

Python specific notes:
This method is the default initializer of the object.

read

Signature: void **read** (string path)

Description: Reads the LVS object from the file.

This method employs the native format of KLayout.

read_l2n

Signature: void **read_l2n** (string path)

Description: Reads the LayoutToNetlist part of the object from a file.

This method employs the native format of KLayout.

reference

Signature: Netlist ptr **reference**

Description: Gets the reference netlist.

Python specific notes:
The object exposes a readable attribute 'reference'. This is the getter.

reference=

Signature: void **reference=** (Netlist ptr reference_netlist)

Description: Sets the reference netlist.

This will set the reference netlist used inside compare as the second netlist to compare against the layout-extracted netlist.

The LVS object will take ownership over the netlist - i.e. if it goes out of scope, the reference netlist is deleted.

Python specific notes:
The object exposes a writable attribute 'reference'. This is the setter.

write

Signature: void **write** (string path, bool short_format = false)

Description: Writes the LVS object to a file.

This method employs the native format of KLayout.

write_l2n

Signature: void **write_l2n** (string path, bool short_format = false)

Description: Writes the LayoutToNetlist part of the object to a file.

This method employs the native format of KLayout.

xref

Signature: NetlistCrossReference ptr **xref**

Description: Gets the cross-reference object

The cross-reference object is created while comparing the layout-extracted netlist against the reference netlist - i.e. during compare. Before compare is called, this object is nil. It holds the results of the comparison - a cross-reference between the nets and other objects in the match case and a listing of non-matching nets and other objects for the non-matching cases. See NetlistCrossReference for more details.

4.184. API reference - Class TextFilter

Notation used in Ruby API documentation

Module: db

Description: A generic text filter adaptor

Text filters are an efficient way to filter texts from a Texts collection. To apply a filter, derive your own filter class and pass an instance to Texts#filter or Texts#filtered method.

Conceptually, these methods take each text from the collection and present it to the filter's 'selected' method. Based on the result of this evaluation, the text is kept or discarded.

The magic happens when deep mode text collections are involved. In that case, the filter will use as few calls as possible and exploit the hierarchical compression if possible. It needs to know however, how the filter behaves. You need to configure the filter by calling is_isotropic, is_scale_invariant or is_isotropic_and_scale_invariant before using the filter.

You can skip this step, but the filter algorithm will assume the worst case then. This usually leads to cell variant formation which is not always desired and blows up the hierarchy.

Here is some example that filters texts with a given string length:

```
class TextStringLengthFilter < RBA::TextFilter

  # Constructor
  def initialize(string_length)
    self.is_isotropic_and_scale_invariant   # orientation and scale do not matter
    @string_length = string_length
  end

  # Select texts with given string length
  def selected(text)
    return text.string.size == @string_length
  end

end

texts = ... # some Texts object
with_length_3 = edges.filtered(TextStringLengthFilter::new(3))
```

This class has been introduced in version 0.29.

Public constructors

new TextFilter ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference
	void	**_manage**	Marks the object as managed by the script side.

	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**is_isotropic**		Indicates that the filter has isotropic properties
	void	**is_isotropic_and_scale_invariant**		Indicates that the filter is isotropic and scale invariant
	void	**is_scale_invariant**		Indicates that the filter is scale invariant
[virtual,const]	bool	**selected**	(const Text text)	Selects a text
	void	**wants_variants=**	(bool flag)	Sets a value indicating whether the filter prefers cell variants
[const]	bool	**wants_variants?**		Gets a value indicating whether the filter prefers cell variants

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_isotropic

Signature: void **is_isotropic**

Description: Indicates that the filter has isotropic properties

Call this method before using the filter to indicate that the selection is independent of the orientation of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

Examples for isotropic (polygon) filters are area or perimeter filters. The area or perimeter of a polygon depends on the scale, but not on the orientation of the polygon.

is_isotropic_and_scale_invariant

Signature: void **is_isotropic_and_scale_invariant**

Description: Indicates that the filter is isotropic and scale invariant

Call this method before using the filter to indicate that the selection is independent of the scale and orientation of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

An example for such a (polygon) filter is the square selector. Whether a polygon is a square or not does not depend on the polygon's orientation nor scale.

is_scale_invariant

Signature: void **is_scale_invariant**

Description: Indicates that the filter is scale invariant

Call this method before using the filter to indicate that the selection is independent of the scale of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

An example for a scale invariant (polygon) filter is the bounding box aspect ratio (height/width) filter. The definition of heigh and width depends on the orientation, but the ratio is independent on scale.

new

Signature: *[static]* new TextFilter ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

selected

Signature: *[virtual,const]* bool **selected** (const Text text)

Description: Selects a text

This method is the actual payload. It needs to be reimplemented in a derived class. It needs to analyze the text and return 'true' if it should be kept and 'false' if it should be discarded.

wants_variants=

Signature: void **wants_variants=** (bool flag)

Description: Sets a value indicating whether the filter prefers cell variants

This flag must be set before using this filter for hierarchical applications (deep mode). It tells the filter implementation whether cell variants should be created (true, the default) or shape propagation will be applied (false).

This decision needs to be made, if the filter indicates that it will deliver different results for scaled or rotated versions of the shape (see is_isotropic and the other hints). If a cell is present with different qualities - as seen from the top cell - the respective instances need to be differentiated. Cell variant formation is one way, shape propagation the other way. Typically, cell variant formation is less expensive, but the hierarchy will be modified.

Python specific notes:
The object exposes a writable attribute 'wants_variants'. This is the setter.

wants_variants?

Signature: *[const]* bool **wants_variants?**

Description: Gets a value indicating whether the filter prefers cell variants

See wants_variants= for details.

Python specific notes:
The object exposes a readable attribute 'wants_variants'. This is the getter.

4.185. API reference - Class TextOperator

Notation used in Ruby API documentation

Module: db

Description: A generic text operator

Text processors are an efficient way to process texts from an text collection. To apply a processor, derive your own operator class and pass an instance to the Texts#processed or Texts#process method.

Conceptually, these methods take each text from the edge pair collection and present it to the operator's 'process' method. The result of this call is a list of zero to many output texts derived from the input text. The output text collection is the sum over all these individual results.

The magic happens when deep mode text collections are involved. In that case, the processor will use as few calls as possible and exploit the hierarchical compression if possible. It needs to know however, how the operator behaves. You need to configure the operator by calling is_isotropic, is_scale_invariant or is_isotropic_and_scale_invariant before using it.

You can skip this step, but the processor algorithm will assume the worst case then. This usually leads to cell variant formation which is not always desired and blows up the hierarchy.

Here is some example that replaces the text string:

```
class ReplaceTextString < RBA::TextOperator

  # Constructor
  def initialize
    self.is_isotropic_and_scale_invariant   # orientation and scale do not matter
  end

  # Replaces the string by a number representing the string length
  def process(text)
    new_text = text.dup   # need a copy as we cannot modify the text passed
    new_text.string = text.string.size.to_s
    return [ new_text ]
  end

end

texts = ... # some Texts object
modified = texts.processed(ReplaceTextString::new)
```

This class has been introduced in version 0.29.

Public constructors

new TextOperator ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference

	void	_manage		Marks the object as managed by the script side.
	void	_unmanage		Marks the object as no longer owned by the script side.
	void	is_isotropic		Indicates that the filter has isotropic properties
	void	is_isotropic_and_scale_invariant		Indicates that the filter is isotropic and scale invariant
	void	is_scale_invariant		Indicates that the filter is scale invariant
[virtual,const]	Text[]	process	(const Text shape)	Processes a shape
	void	wants_variants=	(bool flag)	Sets a value indicating whether the filter prefers cell variants
[const]	bool	wants_variants?		Gets a value indicating whether the filter prefers cell variants

Deprecated methods (protected, public, static, non-static and constructors)

	void	create	Use of this method is deprecated. Use _create instead
	void	destroy	Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	is_const_object?	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void _**create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void _**destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool _**destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_isotropic

Signature: void **is_isotropic**

Description: Indicates that the filter has isotropic properties

Call this method before using the filter to indicate that the selection is independent of the orientation of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

Examples for isotropic (polygon) processors are size or shrink operators. Size or shrink is not dependent on orientation unless size or shrink needs to be different in x and y direction.

is_isotropic_and_scale_invariant

Signature: void **is_isotropic_and_scale_invariant**

Description: Indicates that the filter is isotropic and scale invariant

Call this method before using the filter to indicate that the selection is independent of the scale and orientation of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

An example for such a (polygon) processor is the convex decomposition operator. The decomposition of a polygon into convex parts is an operation that is not depending on scale nor orientation.

is_scale_invariant

Signature: void **is_scale_invariant**

Description: Indicates that the filter is scale invariant

Call this method before using the filter to indicate that the selection is independent of the scale of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

An example for a scale invariant (polygon) processor is the rotation operator. Rotation is not depending on scale, but on the original orientation as mirrored versions need to be rotated differently.

new

Signature: *[static]* new TextOperator ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

process

Signature: *[virtual,const]* Text[] **process** (const Text shape)

Description: Processes a shape

This method is the actual payload. It needs to be reimplemented in a derived class. If needs to process the input shape and deliver a list of output shapes. The output list may be empty to entirely discard the input shape. It may also contain more than a single shape. In that case, the number of total shapes may grow during application of the processor.

wants_variants=

Signature: void **wants_variants=** (bool flag)

Description: Sets a value indicating whether the filter prefers cell variants

This flag must be set before using this filter for hierarchical applications (deep mode). It tells the filter implementation whether cell variants should be created (true, the default) or shape propagation will be applied (false).

This decision needs to be made, if the filter indicates that it will deliver different results for scaled or rotated versions of the shape (see is_isotropic and the other hints). If a cell is present with different qualities - as seen from the top cell - the respective instances need to be differentiated. Cell variant formation is one way, shape propagation the other way. Typically, cell variant formation is less expensive, but the hierarchy will be modified.

Python specific notes:
The object exposes a writable attribute 'wants_variants'. This is the setter.

wants_variants?

Signature: *[const]* bool **wants_variants?**

Description: Gets a value indicating whether the filter prefers cell variants

See wants_variants= for details.

Python specific notes:
The object exposes a readable attribute 'wants_variants'. This is the getter.

4.186. API reference - Class TextToPolygonOperator

Notation used in Ruby API documentation

Module: db

Description: A generic text-to-polygon operator

Text processors are an efficient way to process texts from an text collection. To apply a processor, derive your own operator class and pass an instance to the Texts#processed method.

Conceptually, these methods take each text from the text collection and present it to the operator's 'process' method. The result of this call is a list of zero to many output polygons derived from the input text. The output region is the sum over all these individual results.

The magic happens when deep mode text collections are involved. In that case, the processor will use as few calls as possible and exploit the hierarchical compression if possible. It needs to know however, how the operator behaves. You need to configure the operator by calling is_isotropic, is_scale_invariant or is_isotropic_and_scale_invariant before using it.

You can skip this step, but the processor algorithm will assume the worst case then. This usually leads to cell variant formation which is not always desired and blows up the hierarchy.

For a basic example see the TextOperator class, with the exception that this incarnation delivers polygons.

This class has been introduced in version 0.29.

Public constructors

new TextToPolygonOperator ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**is_isotropic**		Indicates that the filter has isotropic properties
	void	**is_isotropic_and_scale_invariant**		Indicates that the filter is isotropic and scale invariant
	void	**is_scale_invariant**		Indicates that the filter is scale invariant
[virtual,const]	Polygon[]	**process**	(const Text shape)	Processes a shape
	void	**wants_variants=**	(bool flag)	Sets a value indicating whether the filter prefers cell variants
[const]	bool	**wants_variants?**		Gets a value indicating whether the filter prefers cell variants

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method

will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_isotropic

Signature: void **is_isotropic**

Description: Indicates that the filter has isotropic properties

Call this method before using the filter to indicate that the selection is independent of the orientation of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

Examples for isotropic (polygon) processors are size or shrink operators. Size or shrink is not dependent on orientation unless size or shrink needs to be different in x and y direction.

is_isotropic_and_scale_invariant

Signature: void **is_isotropic_and_scale_invariant**

Description: Indicates that the filter is isotropic and scale invariant

Call this method before using the filter to indicate that the selection is independent of the scale and orientation of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

An example for such a (polygon) processor is the convex decomposition operator. The decomposition of a polygon into convex parts is an operation that is not depending on scale nor orientation.

is_scale_invariant

Signature: void **is_scale_invariant**

Description: Indicates that the filter is scale invariant

Call this method before using the filter to indicate that the selection is independent of the scale of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

An example for a scale invariant (polygon) processor is the rotation operator. Rotation is not depending on scale, but on the original orientation as mirrored versions need to be rotated differently.

new

Signature: *[static]* new TextToPolygonOperator ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

process

Signature: *[virtual,const]* Polygon[] **process** (const Text shape)

Description: Processes a shape

This method is the actual payload. It needs to be reimplemented in a derived class. If needs to process the input shape and deliver a list of output shapes. The output list may be empty to entirely discard the input shape. It may also contain more than a single shape. In that case, the number of total shapes may grow during application of the processor.

wants_variants=

Signature: void **wants_variants=** (bool flag)

Description: Sets a value indicating whether the filter prefers cell variants

This flag must be set before using this filter for hierarchical applications (deep mode). It tells the filter implementation whether cell variants should be created (true, the default) or shape propagation will be applied (false).

This decision needs to be made, if the filter indicates that it will deliver different results for scaled or rotated versions of the shape (see is_isotropic and the other hints). If a cell is present with different qualities - as seen from the top cell - the respective instances need to be differentiated. Cell variant formation is one way, shape propagation the other way. Typically, cell variant formation is less expensive, but the hierarchy will be modified.

Python specific notes:
The object exposes a writable attribute 'wants_variants'. This is the setter.

wants_variants?

Signature: *[const]* bool **wants_variants?**

Description: Gets a value indicating whether the filter prefers cell variants

See wants_variants= for details.

Python specific notes:
The object exposes a readable attribute 'wants_variants'. This is the getter.

4.187. API reference - Class Texts

Notation used in Ruby API documentation

Module: db

Description: Texts (a collection of texts)

Class hierarchy: Texts » ShapeCollection

Text objects are useful as labels for net names, to identify certain regions and to specify specific locations in general. Text collections provide a way to store - also in a hierarchical fashion - and manipulate a collection of text objects.

Text objects can be turned into polygons by creating small boxes around the texts (polygons). Texts can also be turned into dot-like edges (edges). Texts can be filtered by string, either by matching against a fixed string (with_text) or a glob-style pattern (with_match).

Text collections can be filtered geometrically against a polygon Region using interacting or non-interacting. Vice versa, texts can be used to select polygons from a Region using pull_interacting.

Beside that, text collections can be transformed, flattened and combined, similar to EdgePairs.

This class has been introduced in version 0.27.

Public constructors

new Texts ptr	**new**		Default constructor
new Texts ptr	**new**	(Text[] array)	Constructor from an text array
new Texts ptr	**new**	(const Text text)	Constructor from a single edge pair object
new Texts ptr	**new**	(const Shapes shapes)	Shapes constructor
new Texts ptr	**new**	(const RecursiveShapeIterator shape_iterator)	Constructor from a hierarchical shape set
new Texts ptr	**new**	(const RecursiveShapeIterator shape_iterator, const ICplxTrans trans)	Constructor from a hierarchical shape set with a transformation
new Texts ptr	**new**	(const RecursiveShapeIterator shape_iterator, DeepShapeStore dss)	Creates a hierarchical text collection from an original layer
new Texts ptr	**new**	(const RecursiveShapeIterator shape_iterator, DeepShapeStore dss, const ICplxTrans trans)	Creates a hierarchical text collection from an original layer with a transformation

Public methods

[const]	Texts	**&**	(const Region other)	Returns the texts from this text collection which are inside or on the edge of polygons from the given region
[const]	Texts	**+**	(const Texts other)	Returns the combined text collection of self and the other one
	Texts	**+=**	(const Texts other)	Adds the texts of the other text collection to self

[const]	Texts	**-**	(const Region other)	Returns the texts from this text collection which are not inside or on the edge of polygons from the given region
[const]	const Text ptr	**[]**	(unsigned long n)	Returns the nth text
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const Texts other)	Assigns another object to self
[const]	Box	**bbox**		Return the bounding box of the text collection
	void	**clear**		Clears the text collection
[const]	unsigned long	**count**		Returns the (flat) number of texts in the text collection
[const]	unsigned long	**data_id**		Returns the data ID (a unique identifier for the underlying data storage)
	void	**disable_progress**		Disable progress reporting
[const]	new Texts ptr	**dup**		Creates a copy of self
[const,iter]	Text	**each**		Returns each text of the text collection
[const]	Edges	**edges**		Returns dot-like edges for the texts
	void	**enable_progress**	(string label)	Enable progress reporting
	void	**enable_properties**		Enables properties for the given container.
[const]	Region	**extents**	(int d = 1)	Returns a region with the enlarged bounding boxes of the texts
[const]	Region	**extents**	(int dx, int dy)	Returns a region with the enlarged bounding boxes of the texts
	void	**filter**	(const TextFilter ptr filter)	Applies a generic filter in place (replacing the texts from the Texts collection)
	void	**filter_properties**	(variant[] keys)	Filters properties by certain keys.

[const]	Texts	**filtered**	(const TextFilter ptr filtered)	Applies a generic filter and returns a filtered copy
	void	**flatten**		Explicitly flattens an text collection
[const]	bool	**has_valid_texts?**		Returns true if the text collection is flat and individual texts can be accessed randomly
[const]	unsigned long	**hier_count**		Returns the (hierarchical) number of texts in the text collection
	void	**insert**	(const Text text)	Inserts a text into the collection
	void	**insert**	(const Texts texts)	Inserts all texts from the other text collection into this collection
[const]	void	**insert_into**	(Layout ptr layout, unsigned int cell_index, unsigned int layer)	Inserts this texts into the given layout, below the given cell and into the given layer.
[const]	void	**insert_into_as_polygons**	(Layout ptr layout, unsigned int cell_index, unsigned int layer, int e)	Inserts this texts into the given layout, below the given cell and into the given layer.
[const]	Texts	**interacting**	(const Region other)	Returns the texts from this text collection which are inside or on the edge of polygons from the given region
[const]	bool	**is_deep?**		Returns true if the edge pair collection is a deep (hierarchical) one
[const]	bool	**is_empty?**		Returns true if the collection is empty
[const]	Texts	**join**	(const Texts other)	Returns the combined text collection of self and the other one
	Texts	**join_with**	(const Texts other)	Adds the texts of the other text collection to self
	void	**map_properties**	(map<variant,variant> key_map)	Maps properties by name key.
	Texts	**move**	(const Vector p)	Moves the text collection
	Texts	**move**	(int x, int y)	Moves the text collection
[const]	Texts	**moved**	(const Vector p)	Returns the moved text collection (does not modify self)
[const]	Texts	**moved**	(int x, int y)	Returns the moved edge pair collection (does not modify self)
[const]	Texts	**not_interacting**	(const Region other)	Returns the texts from this text collection which are not inside or on the edge of polygons from the given region

[const]	Region	**polygons**	(int e = 1)	Converts the edge pairs to polygons
	void	**process**	(const TextOperator ptr process)	Applies a generic text processor in place (replacing the texts from the text collection)
[const]	Texts	**processed**	(const TextOperator ptr processed)	Applies a generic text processor and returns a processed copy
[const]	Region	**processed**	(const TextToPolygonOperato ptr processed)	Applies a generic text-to-polygon processor and returns a region with the results
[const]	Region	**pull_interacting**	(const Region other)	Returns all polygons of "other" which are including texts of this text set
	void	**remove_properties**		Removes properties for the given container.
	Texts	**select_interacting**	(const Region other)	Selects the texts from this text collection which are inside or on the edge of polygons from the given region
	Texts	**select_not_interactir**	(const Region other)	Selects the texts from this text collection which are not inside or on the edge of polygons from the given region
	void	**swap**	(Texts other)	Swap the contents of this collection with the contents of another collection
[const]	string	**to_s**		Converts the text collection to a string
[const]	string	**to_s**	(unsigned long max_count)	Converts the text collection to a string
	Texts	**transform**	(const Trans t)	Transform the text collection (modifies self)
	Texts	**transform**	(const ICplxTrans t)	Transform the text collection with a complex transformation (modifies self)
[const]	Texts	**transformed**	(const Trans t)	Transform the edge pair collection
[const]	Texts	**transformed**	(const ICplxTrans t)	Transform the text collection with a complex transformation
[const]	Texts	**with_match**	(string pattern, bool inverse)	Filter the text by glob pattern
[const]	Texts	**with_text**	(string text, bool inverse)	Filter the text by text string
[const]	void	**write**	(string filename)	Writes the region to a file

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead

[const]	bool	**destroyed?**		Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**		Use of this method is deprecated. Use _is_const_object? instead
[const]	unsigned long	**size**		Use of this method is deprecated. Use count instead
	Texts	**transform_icplx**	(const ICplxTrans t)	Use of this method is deprecated. Use transform instead
[const]	Texts	**transformed_icplx**	(const ICplxTrans t)	Use of this method is deprecated. Use transformed instead

Detailed description

&

Signature: *[const]* Texts **&** (const Region other)

Description: Returns the texts from this text collection which are inside or on the edge of polygons from the given region

Returns: A new text collection containing the texts inside or on the edge of polygons from the region

+

Signature: *[const]* Texts **+** (const Texts other)

Description: Returns the combined text collection of self and the other one

Returns: The resulting text collection

This operator adds the texts of the other collection to self and returns a new combined set.

The 'join' alias has been introduced in version 0.28.12.

+=

Signature: Texts **+=** (const Texts other)

Description: Adds the texts of the other text collection to self

Returns: The text collection after modification (self)

This operator adds the texts of the other collection to self.

Note that in Ruby, the '+=' operator actually does not exist, but is emulated by '+' followed by an assignment. This is less efficient than the in-place operation, so it is recommended to use 'join_with' instead.

The 'join_with' alias has been introduced in version 0.28.12.

-

Signature: *[const]* Texts **-** (const Region other)

Description: Returns the texts from this text collection which are not inside or on the edge of polygons from the given region

Returns: A new text collection containing the texts not inside or on the edge of polygons from the region

[]

Signature: *[const]* const Text ptr **[]** (unsigned long n)

Description: Returns the nth text

This method returns nil if the index is out of range. It is available for flat texts only - i.e. those for which has_valid_texts? is true. Use flatten to explicitly flatten an text collection.

The each iterator is the more general approach to access the texts.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const Texts other)

Description: Assigns another object to self

bbox

Signature: *[const]* Box **bbox**

Description: Return the bounding box of the text collection

The bounding box is the box enclosing all origins of all texts.

clear

Signature: void **clear**

Description: Clears the text collection

count

Signature: *[const]* unsigned long **count**

Description: Returns the (flat) number of texts in the text collection

The count is computed 'as if flat', i.e. texts inside a cell are multiplied by the number of times a cell is instantiated.

Starting with version 0.27, the method is called 'count' for consistency with Region. 'size' is still provided as an alias.

Python specific notes:
This method is also available as 'len(object)'.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

data_id

Signature: *[const]* unsigned long **data_id**

Description: Returns the data ID (a unique identifier for the underlying data storage)

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

disable_progress

Signature: void **disable_progress**

Description: Disable progress reporting

Calling this method will disable progress reporting. See enable_progress.

dup

Signature: *[const]* new Texts ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

each

Signature: *[const,iter]* Text **each**

Description: Returns each text of the text collection

Python specific notes:
This method enables iteration of the object.

edges

Signature: *[const]* Edges **edges**

Description: Returns dot-like edges for the texts

Returns: An edge collection containing the individual, dot-like edges

enable_progress

Signature: void **enable_progress** (string label)

Description: Enable progress reporting

After calling this method, the text collection will report the progress through a progress bar while expensive operations are running. The label is a text which is put in front of the progress bar. Using a progress bar will imply a performance penalty of a few percent typically.

enable_properties

Signature: void **enable_properties**

Description: Enables properties for the given container.

This method has an effect mainly on original layers and will import properties from such layers. By default, properties are not enabled on original layers. Alternatively you can apply filter_properties or map_properties to enable properties with a specific name key.

This method has been introduced in version 0.28.4.

extents

(1) Signature: *[const]* Region **extents** (int d = 1)

Description: Returns a region with the enlarged bounding boxes of the texts

Text bounding boxes are point-like boxes which vanish unless an enlargement of >0 is specified. The bounding box is centered at the text's location. The boxes will not be merged, so it is possible to determine overlaps of these boxes for example.

(2) Signature: *[const]* Region **extents** (int dx, int dy)

Description: Returns a region with the enlarged bounding boxes of the texts

This method acts like the other version of extents, but allows giving different enlargements for x and y direction.

filter

Signature: void **filter** (const TextFilter ptr filter)

Description: Applies a generic filter in place (replacing the texts from the Texts collection)

See TextFilter for a description of this feature.

This method has been introduced in version 0.29.

filter_properties

Signature: void **filter_properties** (variant[] keys)

Description: Filters properties by certain keys.

Calling this method on a container will reduce the properties to values with name keys from the 'keys' list. As a side effect, this method enables properties on original layers.

This method has been introduced in version 0.28.4.

filtered

Signature: *[const]* Texts **filtered** (const TextFilter ptr filtered)

Description: Applies a generic filter and returns a filtered copy

See TextFilter for a description of this feature.

This method has been introduced in version 0.29.

flatten

Signature: void **flatten**

Description: Explicitly flattens an text collection

If the collection is already flat (i.e. has_valid_texts? returns true), this method will not change the collection.

has_valid_texts?

Signature: *[const]* bool **has_valid_texts?**

Description: Returns true if the text collection is flat and individual texts can be accessed randomly

hier_count

Signature: *[const]* unsigned long **hier_count**

Description: Returns the (hierarchical) number of texts in the text collection

The count is computed 'hierarchical', i.e. texts inside a cell are counted once even if the cell is instantiated multiple times.

This method has been introduced in version 0.27.

insert

(1) Signature: void **insert** (const Text text)

Description: Inserts a text into the collection

(2) Signature: void **insert** (const Texts texts)

Description: Inserts all texts from the other text collection into this collection

insert_into

Signature: *[const]* void **insert_into** (Layout ptr layout, unsigned int cell_index, unsigned int layer)

Description: Inserts this texts into the given layout, below the given cell and into the given layer.

If the text collection is a hierarchical one, a suitable hierarchy will be built below the top cell or and existing hierarchy will be reused.

insert_into_as_polygons

Signature: *[const]* void **insert_into_as_polygons** (Layout ptr layout, unsigned int cell_index, unsigned int layer, int e)

Description: Inserts this texts into the given layout, below the given cell and into the given layer.

If the text collection is a hierarchical one, a suitable hierarchy will be built below the top cell or and existing hierarchy will be reused.

The texts will be converted to polygons with the enlargement value given be 'e'. See polygon or extents for details.

interacting

Signature: *[const]* Texts **interacting** (const Region other)

Description: Returns the texts from this text collection which are inside or on the edge of polygons from the given region

Returns: A new text collection containing the texts inside or on the edge of polygons from the region

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_deep?

Signature: *[const]* bool **is_deep?**

Description: Returns true if the edge pair collection is a deep (hierarchical) one

is_empty?

Signature: *[const]* bool **is_empty?**

Description: Returns true if the collection is empty

join

Signature: *[const]* Texts **join** (const Texts other)

Description: Returns the combined text collection of self and the other one

Returns: The resulting text collection

This operator adds the texts of the other collection to self and returns a new combined set.

The 'join' alias has been introduced in version 0.28.12.

join_with

Signature: Texts **join_with** (const Texts other)

Description: Adds the texts of the other text collection to self

Returns: The text collection after modification (self)

This operator adds the texts of the other collection to self.

Note that in Ruby, the '+=' operator actually does not exist, but is emulated by '+' followed by an assignment. This is less efficient than the in-place operation, so it is recommended to use 'join_with' instead.

The 'join_with' alias has been introduced in version 0.28.12.

map_properties

Signature: void **map_properties** (map<variant,variant> key_map)

Description: Maps properties by name key.

Calling this method on a container will reduce the properties to values with name keys from the 'keys' hash and renames the properties. Properties not listed in the key map will be removed. As a side effect, this method enables properties on original layers.

This method has been introduced in version 0.28.4.

move

(1) Signature: Texts **move** (const Vector p)

Description: Moves the text collection

p: The distance to move the texts.

Returns: The moved texts (self).

Moves the texts by the given offset and returns the moved text collection. The text collection is overwritten.

(2) Signature: Texts **move** (int x, int y)

Description: Moves the text collection

x: The x distance to move the texts.

y: The y distance to move the texts.

Returns: The moved texts (self).

Moves the edge pairs by the given offset and returns the moved texts. The edge pair collection is overwritten.

moved

(1) Signature: *[const]* Texts **moved** (const Vector p)

Description: Returns the moved text collection (does not modify self)

p: The distance to move the texts.

Returns: The moved texts.

Moves the texts by the given offset and returns the moved texts. The text collection is not modified.

(2) Signature: *[const]* Texts **moved** (int x, int y)

Description: Returns the moved edge pair collection (does not modify self)

x: The x distance to move the texts.

y: The y distance to move the texts.

Returns: The moved texts.

Moves the texts by the given offset and returns the moved texts. The text collection is not modified.

new

(1) Signature: *[static]* new Texts ptr **new**

Description: Default constructor

This constructor creates an empty text collection.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new Texts ptr **new** (Text[] array)

Description: Constructor from an text array

This constructor creates an text collection from an array of Text objects.

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new Texts ptr **new** (const Text text)

Description: Constructor from a single edge pair object

This constructor creates an text collection with a single text.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new Texts ptr **new** (const Shapes shapes)

Description: Shapes constructor

This constructor creates an text collection from a Shapes collection.

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new Texts ptr **new** (const RecursiveShapeIterator shape_iterator)

Description: Constructor from a hierarchical shape set

This constructor creates a text collection from the shapes delivered by the given recursive shape iterator. Only texts are taken from the shape set and other shapes are ignored. This method allows feeding the text collection from a hierarchy of cells.

```
layout = ... # a layout
cell   = ... # the index of the initial cell
layer  = ... # the index of the layer from where to take the shapes from
r = RBA::Texts::new(layout.begin_shapes(cell, layer))
```

Python specific notes:
This method is the default initializer of the object.

(6) Signature: *[static]* new Texts ptr **new** (const RecursiveShapeIterator shape_iterator, const ICplxTrans trans)

Description: Constructor from a hierarchical shape set with a transformation

This constructor creates a text collection from the shapes delivered by the given recursive shape iterator. Only texts are taken from the shape set and other shapes are ignored. The given transformation is applied to each text taken. This method allows feeding the text collection from a hierarchy of cells. The transformation is useful to scale to a specific database unit for example.

```
layout = ... # a layout
cell   = ... # the index of the initial cell
layer  = ... # the index of the layer from where to take the shapes from
dbu    = 0.1 # the target database unit
r = RBA::Texts::new(layout.begin_shapes(cell, layer),
 RBA::ICplxTrans::new(layout.dbu / dbu))
```

Python specific notes:
This method is the default initializer of the object.

(7) Signature: *[static]* new Texts ptr **new** (const RecursiveShapeIterator shape_iterator, DeepShapeStore dss)

Description: Creates a hierarchical text collection from an original layer

This constructor creates a text collection from the shapes delivered by the given recursive shape iterator. This version will create a hierarchical text collection which supports hierarchical operations.

```
dss    = RBA::DeepShapeStore::new
layout = ... # a layout
cell   = ... # the index of the initial cell
layer  = ... # the index of the layer from where to take the shapes from
r = RBA::Texts::new(layout.begin_shapes(cell, layer))
```

Python specific notes:
This method is the default initializer of the object.

(8) Signature: *[static]* new Texts ptr **new** (const RecursiveShapeIterator shape_iterator, DeepShapeStore dss, const ICplxTrans trans)

Description: Creates a hierarchical text collection from an original layer with a transformation

This constructor creates a text collection from the shapes delivered by the given recursive shape iterator. This version will create a hierarchical text collection which supports hierarchical operations. The transformation is useful to scale to a specific database unit for example.

```
dss    = RBA::DeepShapeStore::new
layout = ... # a layout
cell   = ... # the index of the initial cell
layer  = ... # the index of the layer from where to take the shapes from
dbu    = 0.1 # the target database unit
r = RBA::Texts::new(layout.begin_shapes(cell, layer),
 RBA::ICplxTrans::new(layout.dbu / dbu))
```

Python specific notes:
This method is the default initializer of the object.

not_interacting

Signature: *[const]* Texts **not_interacting** (const Region other)

Description: Returns the texts from this text collection which are not inside or on the edge of polygons from the given region

Returns: A new text collection containing the texts not inside or on the edge of polygons from the region

polygons

Signature: *[const]* Region **polygons** (int e = 1)

Description: Converts the edge pairs to polygons

This method creates polygons from the texts. This is equivalent to calling extents.

process

Signature: void **process** (const TextOperator ptr process)

Description: Applies a generic text processor in place (replacing the texts from the text collection)

See TextProcessor for a description of this feature.

This method has been introduced in version 0.29.

processed

(1) Signature: *[const]* Texts **processed** (const TextOperator ptr processed)

Description: Applies a generic text processor and returns a processed copy

See TextProcessor for a description of this feature.

This method has been introduced in version 0.29.

(2) Signature: *[const]* Region **processed** (const TextToPolygonOperator ptr processed)

Description: Applies a generic text-to-polygon processor and returns a region with the results

See TextToPolygonProcessor for a description of this feature.

This method has been introduced in version 0.29.

pull_interacting

Signature: *[const]* Region **pull_interacting** (const Region other)

Description: Returns all polygons of "other" which are including texts of this text set

Returns: The region after the polygons have been selected (from other)

The "pull_..." method is similar to "select_..." but works the opposite way: it selects shapes from the argument region rather than self. In a deep (hierarchical) context the output region will be hierarchically aligned with self, so the "pull_..." method provide a way for re-hierarchization.

Merged semantics applies for the polygon region.

remove_properties

Signature: void **remove_properties**

Description: Removes properties for the given container.

This will remove all properties on the given container.

This method has been introduced in version 0.28.4.

select_interacting

Signature: Texts **select_interacting** (const Region other)

Description: Selects the texts from this text collection which are inside or on the edge of polygons from the given region

Returns: A text collection after the texts have been selected (self)

In contrast to interacting, this method will modify self.

select_not_interacting

Signature: Texts **select_not_interacting** (const Region other)

Description: Selects the texts from this text collection which are not inside or on the edge of polygons from the given region

Returns: A text collection after the texts have been selected (self)

In contrast to interacting, this method will modify self.

size

Signature: *[const]* unsigned long **size**

Description: Returns the (flat) number of texts in the text collection

Use of this method is deprecated. Use count instead

The count is computed 'as if flat', i.e. texts inside a cell are multiplied by the number of times a cell is instantiated.

Starting with version 0.27, the method is called 'count' for consistency with Region. 'size' is still provided as an alias.

Python specific notes:
This method is also available as 'len(object)'.

swap

Signature: void **swap** (Texts other)

Description: Swap the contents of this collection with the contents of another collection

This method is useful to avoid excessive memory allocation in some cases. For managed memory languages such as Ruby, those cases will be rare.

to_s

(1) Signature: *[const]* string **to_s**

Description: Converts the text collection to a string

The length of the output is limited to 20 texts to avoid giant strings on large collections. For full output use "to_s" with a maximum count parameter.

Python specific notes:
This method is also available as 'str(object)'.

(2) Signature: *[const]* string **to_s** (unsigned long max_count)

Description: Converts the text collection to a string

This version allows specification of the maximum number of texts contained in the string.

transform

(1) Signature: Texts **transform** (const Trans t)

Description: Transform the text collection (modifies self)

t: The transformation to apply.

Returns: The transformed text collection.

Transforms the text collection with the given transformation. This version modifies the text collection and returns a reference to self.

(2) Signature: Texts **transform** (const ICplxTrans t)

Description: Transform the text collection with a complex transformation (modifies self)

t: The transformation to apply.

Returns: The transformed text collection.

Transforms the text collection with the given transformation. This version modifies the text collection and returns a reference to self.

transform_icplx

Signature: Texts **transform_icplx** (const ICplxTrans t)

Description: Transform the text collection with a complex transformation (modifies self)

t: The transformation to apply.

Returns: The transformed text collection.

Use of this method is deprecated. Use transform instead

Transforms the text collection with the given transformation. This version modifies the text collection and returns a reference to self.

transformed

(1) Signature: *[const]* Texts **transformed** (const Trans t)

Description: Transform the edge pair collection

t: The transformation to apply.

Returns: The transformed texts.

Transforms the texts with the given transformation. Does not modify the edge pair collection but returns the transformed texts.

(2) Signature: *[const]* Texts **transformed** (const ICplxTrans t)

Description: Transform the text collection with a complex transformation

t: The transformation to apply.

Returns: The transformed texts.

Transforms the text with the given complex transformation. Does not modify the text collection but returns the transformed texts.

transformed_icplx

Signature: *[const]* Texts **transformed_icplx** (const ICplxTrans t)

Description: Transform the text collection with a complex transformation

t: The transformation to apply.

Returns: The transformed texts.

Use of this method is deprecated. Use transformed instead

Transforms the text with the given complex transformation. Does not modify the text collection but returns the transformed texts.

with_match

Signature: *[const]* Texts **with_match** (string pattern, bool inverse)

Description: Filter the text by glob pattern

"pattern" is a glob-style pattern (e.g. "A*" will select all texts starting with a capital "A"). If "inverse" is false, this method returns the texts matching the pattern. If "inverse" is true, this method returns the texts not matching the pattern.

with_text

Signature: *[const]* Texts **with_text** (string text, bool inverse)

Description: Filter the text by text string

If "inverse" is false, this method returns the texts with the given string. If "inverse" is true, this method returns the texts not having the given string.

write

Signature: *[const]* void **write** (string filename)

Description: Writes the region to a file

This method is provided for debugging purposes. It writes the object to a flat layer 0/0 in a single top cell.

This method has been introduced in version 0.29.

4.188. API reference - Class ShapeCollection

Notation used in Ruby API documentation

Module: db

Description: A base class for the shape collections (\Region, \Edges, \EdgePairs and \Texts)

This class has been introduced in version 0.27.

Public constructors

new ShapeCollection ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference
	void	**_manage**	Marks the object as managed by the script side.
	void	**_unmanage**	Marks the object as no longer owned by the script side.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new ShapeCollection ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

4.189. API reference - Class RdbReference

Notation used in Ruby API documentation

Module: rdb

Description: A cell reference inside the report database

This class describes a cell reference. Such reference object can be attached to cells to describe instantiations of them in parent cells. Not necessarily all instantiations of a cell in the layout database are represented by references and in some cases there might even be no references at all. The references are merely a hint how a marker must be displayed in the context of any other, potentially parent, cell in the layout database.

Public constructors

new RdbReference ptr	**new**	(const DCplxTrans trans, unsigned long parent_cell_id)	Creates a reference with a given transformation and parent cell ID

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const RdbReferenc other)	Assigns another object to self
[const]	const ReportDatabase ptr	**database**		Gets the database object that category is associated with
	ReportDatabase ptr	**database**		Gets the database object that category is associated with (non-const version)
[const]	new RdbReference ptr	**dup**		Creates a copy of self
[const]	unsigned long	**parent_cell_id**		Gets parent cell ID for this reference
	void	**parent_cell_id=**	(unsigned long id)	Sets the parent cell ID for this reference
[const]	DCplxTrans	**trans**		Gets the transformation for this reference
	void	**trans=**	(const DCplxTrans trans)	Sets the transformation for this reference

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method

will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const RdbReference other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

database

(1) Signature: *[const]* const ReportDatabase ptr **database**

Description: Gets the database object that category is associated with

This method has been introduced in version 0.23.

(2) Signature: ReportDatabase ptr **database**

Description: Gets the database object that category is associated with (non-const version)

This method has been introduced in version 0.29.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new RdbReference ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new RdbReference ptr **new** (const DCplxTrans trans, unsigned long parent_cell_id)

Description: Creates a reference with a given transformation and parent cell ID

Python specific notes:
This method is the default initializer of the object.

parent_cell_id

Signature: *[const]* unsigned long **parent_cell_id**

Description: Gets parent cell ID for this reference

Returns: The parent cell ID

Python specific notes:
The object exposes a readable attribute 'parent_cell_id'. This is the getter.

parent_cell_id=

Signature: void **parent_cell_id=** (unsigned long id)

Description: Sets the parent cell ID for this reference

Python specific notes:
The object exposes a writable attribute 'parent_cell_id'. This is the setter.

trans

Signature: *[const]* DCplxTrans **trans**

Description: Gets the transformation for this reference

Returns: The transformation

The transformation describes the transformation of the child cell into the parent cell. In that sense that is the usual transformation of a cell reference.

Python specific notes:
The object exposes a readable attribute 'trans'. This is the getter.

trans=

Signature: void **trans=** (const DCplxTrans trans)

Description: Sets the transformation for this reference

Python specific notes:
The object exposes a writable attribute 'trans'. This is the setter.

4.190. API reference - Class RdbCell

Notation used in Ruby API documentation

Module: rdb

Description: A cell inside the report database

This class represents a cell in the report database. There is not necessarily a 1:1 correspondence of RDB cells and layout database cells. Cells have an ID, a name, optionally a variant name and a set of references which describe at least one example instantiation in some parent cell. The references do not necessarily map to references or cover all references in the layout database.

Public constructors

new RdbCell ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**add_reference**	(const RdbRef ref)	Adds a reference to the references of this cell
	void	**clear_references**		Removes all references from this cell
[const]	const ReportDatabase ptr	**database**		Gets the database object that category is associated with
	ReportDatabase ptr	**database**		Gets the database object that category is associated with (non-const version)
[const,iter]	RdbItem	**each_item**		Iterates over all items inside the database which are associated with this cell
[iter]	RdbItem	**each_item**		Iterates over all items inside the database which are associated with this cell (non-const version)
[const,iter]	RdbReference	**each_reference**		Iterates over all references
[iter]	RdbReference	**each_reference**		Iterates over all references (non-const version)
[const]	string	**name**		Gets the cell name
[const]	unsigned long	**num_items**		Gets the number of items for this cell

[const]	unsigned long	**num_items_visited**	Gets the number of visited items for this cell
[const]	string	**qname**	Gets the cell's qualified name
[const]	unsigned long	**rdb_id**	Gets the cell ID
[const]	string	**variant**	Gets the cell variant name

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

add_reference

Signature: void **add_reference** (const RdbReference ref)

Description: Adds a reference to the references of this cell

ref: The reference to add.

clear_references

Signature: void **clear_references**

Description: Removes all references from this cell

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

database

(1) Signature: *[const]* const ReportDatabase ptr **database**

Description: Gets the database object that category is associated with

This method has been introduced in version 0.23.

(2) Signature: ReportDatabase ptr **database**

Description: Gets the database object that category is associated with (non-const version)

This method has been introduced in version 0.29.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

each_item

(1) Signature: *[const,iter]* RdbItem **each_item**

Description: Iterates over all items inside the database which are associated with this cell

This method has been introduced in version 0.23.

(2) Signature: *[iter]* RdbItem **each_item**

Description: Iterates over all items inside the database which are associated with this cell (non-const version)

This method has been introduced in version 0.29.

each_reference

(1) Signature: *[const,iter]* RdbReference **each_reference**

Description: Iterates over all references

(2) Signature: *[iter]* RdbReference **each_reference**

Description: Iterates over all references (non-const version)

This method has been introduced in version 0.23.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

name

Signature: *[const]* string **name**

Description: Gets the cell name

Returns: The cell name

The cell name is an string that identifies the category in the database. Additionally, a cell may carry a variant identifier which is a string that uniquely identifies a cell in the context of its variants. The "qualified name" contains both the cell name and the variant name. Cell names are also used to identify report database cell's with layout cells.

new

Signature: *[static]* new RdbCell ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

num_items

Signature: *[const]* unsigned long **num_items**

Description: Gets the number of items for this cell

num_items_visited

Signature: *[const]* unsigned long **num_items_visited**

Description: Gets the number of visited items for this cell

qname

Signature: *[const]* string **qname**

Description: Gets the cell's qualified name

Returns: The qualified name

The qualified name is a combination of the cell name and optionally the variant name. It is used to identify the cell by name in a unique way.

rdb_id

Signature: *[const]* unsigned long **rdb_id**

Description: Gets the cell ID

Returns: The cell ID

The cell ID is an integer that uniquely identifies the cell. It is used for referring to a cell in RdbItem for example.

variant

Signature: *[const]* string **variant**

Description: Gets the cell variant name

Returns: The cell variant name

A variant name additionally identifies the cell when multiple cells with the same name are present. A variant name is either assigned automatically or set when creating a cell.

4.191. API reference - Class RdbCategory

Notation used in Ruby API documentation

Module: rdb

Description: A category inside the report database

Every item in the report database is assigned to a category. A category is a DRC rule check for example. Categories can be organized hierarchically, i.e. a category may have sub-categories. Item counts are summarized for categories and items belonging to sub-categories of one category can be browsed together for example. As a general rule, categories not being leaf categories (having child categories) may not have items.

Public constructors

new RdbCategory ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	const ReportDatabase ptr	**database**		Gets the database object that category is associated with
[const]	string	**description**		Gets the category description
	void	**description=**	(string description)	Sets the category description
[const,iter]	RdbItem	**each_item**		Iterates over all items inside the database which are associated with this category
[iter]	RdbItem	**each_item**		Iterates over all items inside the database which are associated with this category (non-const version)
[const,iter]	RdbCategory	**each_sub_category**		Iterates over all sub-categories
[iter]	RdbCategory	**each_sub_category**		Iterates over all sub-categories (non-const version)
[const]	string	**name**		Gets the category name
[const]	unsigned long	**num_items**		Gets the number of items in this category

[const]	unsigned long	**num_items_visited**		Gets the number of visited items in this category
[const]	const RdbCategory ptr	**parent**		Gets the parent category of this category
	RdbCategory ptr	**parent**		Gets the parent category of this category (non-const version)
[const]	string	**path**		Gets the category path
[const]	unsigned long	**rdb_id**		Gets the category ID
	void	**scan_collection**	(RdbCell ptr cell, const CplxTrans trans, const Region region, bool flat = false, bool with_properties = true)	Turns the given region into a hierarchical or flat report database
	void	**scan_collection**	(RdbCell ptr cell, const CplxTrans trans, const Edges edges, bool flat = false, bool with_properties = true)	Turns the given edge collection into a hierarchical or flat report database
	void	**scan_collection**	(RdbCell ptr cell, const CplxTrans trans, const EdgePairs edge_pairs, bool flat = false, bool with_properties = true)	Turns the given edge pair collection into a hierarchical or flat report database
	void	**scan_collection**	(RdbCell ptr cell, const CplxTrans trans, const Texts texts, bool flat = false, bool with_properties = true)	Turns the given edge pair collection into a hierarchical or flat report database
	void	**scan_layer**	(const Layout layout, unsigned int layer, const Cell ptr cell = nil, int levels = -1,	Scans a layer from a layout into this category, starting with a given cell and a depth specification

			bool with_properties = true)	
	void	scan_shapes	(const RecursiveShapeIterator iter, bool flat = false, bool with_properties = true)	Scans the polygon or edge shapes from the shape iterator into the category

Deprecated methods (protected, public, static, non-static and constructors)

	void	create	Use of this method is deprecated. Use _create instead
	void	destroy	Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	is_const_object?	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

database

Signature: *[const]* const ReportDatabase ptr **database**

Description: Gets the database object that category is associated with

This method has been introduced in version 0.23.

description

Signature: *[const]* string **description**

Description: Gets the category description

Returns: The description string

Python specific notes:
The object exposes a readable attribute 'description'. This is the getter.

description=

Signature: void **description=** (string description)

Description: Sets the category description

description: The description string

Python specific notes:
The object exposes a writable attribute 'description'. This is the setter.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

each_item

(1) Signature: *[const,iter]* RdbItem **each_item**

Description: Iterates over all items inside the database which are associated with this category

This method has been introduced in version 0.23.

(2) Signature: *[iter]* RdbItem **each_item**

Description: Iterates over all items inside the database which are associated with this category (non-const version)

This method has been introduced in version 0.29.

each_sub_category

(1) Signature: *[const,iter]* RdbCategory **each_sub_category**

Description: Iterates over all sub-categories

The const version has been added in version 0.29.

(2) Signature: *[iter]* RdbCategory **each_sub_category**

Description: Iterates over all sub-categories (non-const version)

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

name

Signature: *[const]* string **name**

Description: Gets the category name

Returns: The category name

The category name is an string that identifies the category in the context of a parent category or inside the database when it is a top level category. The name is not the path name which is a path to a child category and incorporates all names of parent categories.

new

Signature: *[static]* new RdbCategory ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

num_items

Signature: *[const]* unsigned long **num_items**

Description: Gets the number of items in this category

The number of items includes the items in sub-categories of this category.

num_items_visited

Signature: *[const]* unsigned long **num_items_visited**

Description: Gets the number of visited items in this category

The number of items includes the items in sub-categories of this category.

parent

(1) Signature: *[const]* const RdbCategory ptr **parent**

Description: Gets the parent category of this category

Returns: The parent category or nil if this category is a top-level category

The const version has been added in version 0.29.

(2) Signature: RdbCategory ptr **parent**

Description: Gets the parent category of this category (non-const version)

Returns: The parent category or nil if this category is a top-level category

path

Signature: *[const]* string **path**

Description: Gets the category path

Returns: The path for this category

The category path is the category name for top level categories. For child categories, the path contains the names of all parent categories separated by a dot.

rdb_id

Signature: *[const]* unsigned long **rdb_id**

Description: Gets the category ID

Returns: The category ID

The category ID is an integer that uniquely identifies the category. It is used for referring to a category in RdbItem for example.

scan_collection

(1) Signature: void **scan_collection** (RdbCell ptr cell, const CplxTrans trans, const Region region, bool flat = false, bool with_properties = true)

Description: Turns the given region into a hierarchical or flat report database

The exact behavior depends on the nature of the region. If the region is a hierarchical (original or deep) region and the 'flat' argument is false, this method will produce a hierarchical report database in the given category. The 'cell_id' parameter is ignored in this case. Sample references will be produced to supply minimal instantiation information.

If the region is a flat one or the 'flat' argument is true, the region's polygons will be produced as report database items in this category and in the cell given by 'cell_id'.

The transformation argument needs to supply the dbu-to-micron transformation.

If 'with_properties' is true, user properties will be turned into tagged values as well.

This method has been introduced in version 0.26. The 'with_properties' argument has been added in version 0.28.

(2) Signature: void **scan_collection** (RdbCell ptr cell, const CplxTrans trans, const Edges edges, bool flat = false, bool with_properties = true)

Description: Turns the given edge collection into a hierarchical or flat report database

This a another flavour of scan_collection accepting an edge collection.

This method has been introduced in version 0.26. The 'with_properties' argument has been added in version 0.28.

(3) Signature: void **scan_collection** (RdbCell ptr cell, const CplxTrans trans, const EdgePairs edge_pairs, bool flat = false, bool with_properties = true)

Description: Turns the given edge pair collection into a hierarchical or flat report database

This a another flavour of scan_collection accepting an edge pair collection.

This method has been introduced in version 0.26. The 'with_properties' argument has been added in version 0.28.

(4) Signature: void **scan_collection** (RdbCell ptr cell, const CplxTrans trans, const Texts texts, bool flat = false, bool with_properties = true)

Description: Turns the given edge pair collection into a hierarchical or flat report database

This a another flavour of scan_collection accepting a text collection.

This method has been introduced in version 0.28.

scan_layer

Signature: void **scan_layer** (const Layout layout, unsigned int layer, const Cell ptr cell = nil, int levels = -1, bool with_properties = true)

Description: Scans a layer from a layout into this category, starting with a given cell and a depth specification

Creates RDB items for each polygon or edge shape read from the cell and its children in the layout on the given layer and puts them into this category. New cells will be generated when required. "levels" is the number of hierarchy levels to take the child cells from. 0 means to use only "cell" and don't descend, -1 means "all levels". Other settings like database unit, description, top cell etc. are not made in the RDB.

If 'with_properties' is true, user properties will be turned into tagged values as well.

This method has been introduced in version 0.23. The 'with_properties' argument has been added in version 0.28.

scan_shapes

Signature: void **scan_shapes** (const RecursiveShapeIterator iter, bool flat = false, bool with_properties = true)

Description: Scans the polygon or edge shapes from the shape iterator into the category

Creates RDB items for each polygon or edge shape read from the iterator and puts them into this category. A similar, but lower-level method is ReportDatabase#create_items with a RecursiveShapeIterator argument. In contrast to ReportDatabase#create_items, 'scan_shapes' can also produce hierarchical databases if the flat argument is false. In this case, the hierarchy the recursive shape iterator traverses is copied into the report database using sample references.

If 'with_properties' is true, user properties will be turned into tagged values as well.

This method has been introduced in version 0.23. The flat mode argument has been added in version 0.26. The 'with_properties' argument has been added in version 0.28.

4.192. API reference - Class RdbItemValue

Notation used in Ruby API documentation

Module: rdb

Description: A value object inside the report database

Value objects are attached to items to provide markers. An arbitrary number of such value objects can be attached to an item. Currently, a value can represent a box, a polygon or an edge. Geometrical objects are represented in micron units and are therefore "D" type objects (DPolygon, DEdge and DBox).

Public constructors

new RdbItemValue ptr	**new**	(double f)	Creates a value representing a numeric value
new RdbItemValue ptr	**new**	(string s)	Creates a value representing a string
new RdbItemValue ptr	**new**	(const DPolygon p)	Creates a value representing a DPolygon object
new RdbItemValue ptr	**new**	(const DPath p)	Creates a value representing a DPath object
new RdbItemValue ptr	**new**	(const DText t)	Creates a value representing a DText object
new RdbItemValue ptr	**new**	(const DEdge e)	Creates a value representing a DEdge object
new RdbItemValue ptr	**new**	(const DEdgePair ee)	Creates a value representing a DEdgePair object
new RdbItemValue ptr	**new**	(const DBox b)	Creates a value representing a DBox object

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const RdbItem other)	Assigns another object to self
[const]	DBox	**box**		Gets the box if the value represents one.
[const]	new RdbItemValue ptr	**dup**		Creates a copy of self

[const]	DEdge	**edge**		Gets the edge if the value represents one.
[const]	DEdgePair	**edge_pair**		Gets the edge pair if the value represents one.
[const]	double	**float**		Gets the numeric value.
[const]	bool	**is_box?**		Returns true if the value object represents a box
[const]	bool	**is_edge?**		Returns true if the value object represents an edge
[const]	bool	**is_edge_pair?**		Returns true if the value object represents an edge pair
[const]	bool	**is_float?**		Returns true if the value object represents a numeric value
[const]	bool	**is_path?**		Returns true if the value object represents a path
[const]	bool	**is_polygon?**		Returns true if the value object represents a polygon
[const]	bool	**is_string?**		Returns true if the object represents a string value
[const]	bool	**is_text?**		Returns true if the value object represents a text
[const]	DPath	**path**		Gets the path if the value represents one.
[const]	DPolygon	**polygon**		Gets the polygon if the value represents one.
[const]	string	**string**		Gets the string representation of the value.
[const]	unsigned long	**tag_id**		Gets the tag ID if the value is a tagged value or 0 if not
	void	**tag_id=**	(unsigned long id)	Sets the tag ID to make the value a tagged value or 0 to reset it
[const]	DText	**text**		Gets the text if the value represents one.
[const]	string	**to_s**		Converts a value to a string

Public static methods and constants

RdbItemValue ptr	**from_s**	(string s)	Creates a value object from a string

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create	**Signature**: void **_create** **Description**: Ensures the C++ object is created Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
_destroy	**Signature**: void **_destroy** **Description**: Explicitly destroys the object Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
_destroyed?	**Signature**: *[const]* bool **_destroyed?** **Description**: Returns a value indicating whether the object was already destroyed This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
_is_const_object?	**Signature**: *[const]* bool **_is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference This method returns true, if self is a const reference. In that case, only const methods may be called on self.
_manage	**Signature**: void **_manage** **Description**: Marks the object as managed by the script side. After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required. Usually it's not required to call this method. It has been introduced in version 0.24.
_unmanage	**Signature**: void **_unmanage** **Description**: Marks the object as no longer owned by the script side. Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.
assign	**Signature**: void **assign** (const RdbItemValue other) **Description**: Assigns another object to self
box	**Signature**: *[const]* DBox **box** **Description**: Gets the box if the value represents one.

Returns: The DBox object or nil

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new RdbItemValue ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

edge

Signature: *[const]* DEdge **edge**

Description: Gets the edge if the value represents one.

Returns: The DEdge object or nil

edge_pair

Signature: *[const]* DEdgePair **edge_pair**

Description: Gets the edge pair if the value represents one.

Returns: The DEdgePair object or nil

float

Signature: *[const]* double **float**

Description: Gets the numeric value.

Returns: The numeric value or 0

This method has been introduced in version 0.24.

from_s

Signature: *[static]* RdbItemValue ptr **from_s** (string s)

Description: Creates a value object from a string

The string format is the same than obtained by the to_s method.

is_box?	**Signature**: *[const]* bool **is_box?** **Description**: Returns true if the value object represents a box
is_const_object?	**Signature**: *[const]* bool **is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.
is_edge?	**Signature**: *[const]* bool **is_edge?** **Description**: Returns true if the value object represents an edge
is_edge_pair?	**Signature**: *[const]* bool **is_edge_pair?** **Description**: Returns true if the value object represents an edge pair
is_float?	**Signature**: *[const]* bool **is_float?** **Description**: Returns true if the value object represents a numeric value This method has been introduced in version 0.24.
is_path?	**Signature**: *[const]* bool **is_path?** **Description**: Returns true if the value object represents a path This method has been introduced in version 0.22.
is_polygon?	**Signature**: *[const]* bool **is_polygon?** **Description**: Returns true if the value object represents a polygon
is_string?	**Signature**: *[const]* bool **is_string?** **Description**: Returns true if the object represents a string value
is_text?	**Signature**: *[const]* bool **is_text?** **Description**: Returns true if the value object represents a text This method has been introduced in version 0.22.
new	**(1) Signature**: *[static]* new RdbItemValue ptr **new** (double f) **Description**: Creates a value representing a numeric value This variant has been introduced in version 0.24 **Python specific notes:** This method is the default initializer of the object. **(2) Signature**: *[static]* new RdbItemValue ptr **new** (string s) **Description**: Creates a value representing a string **Python specific notes:** This method is the default initializer of the object.

(3) Signature: *[static]* new RdbItemValue ptr **new** (const DPolygon p)

Description: Creates a value representing a DPolygon object

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new RdbItemValue ptr **new** (const DPath p)

Description: Creates a value representing a DPath object

This method has been introduced in version 0.22.

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new RdbItemValue ptr **new** (const DText t)

Description: Creates a value representing a DText object

This method has been introduced in version 0.22.

Python specific notes:
This method is the default initializer of the object.

(6) Signature: *[static]* new RdbItemValue ptr **new** (const DEdge e)

Description: Creates a value representing a DEdge object

Python specific notes:
This method is the default initializer of the object.

(7) Signature: *[static]* new RdbItemValue ptr **new** (const DEdgePair ee)

Description: Creates a value representing a DEdgePair object

Python specific notes:
This method is the default initializer of the object.

(8) Signature: *[static]* new RdbItemValue ptr **new** (const DBox b)

Description: Creates a value representing a DBox object

Python specific notes:
This method is the default initializer of the object.

path

Signature: *[const]* DPath **path**

Description: Gets the path if the value represents one.

Returns: The DPath object

This method has been introduced in version 0.22.

polygon

Signature: *[const]* DPolygon **polygon**

Description: Gets the polygon if the value represents one.

Returns: The DPolygon object

string

Signature: *[const]* string **string**

Description: Gets the string representation of the value.

Returns: The stringThis method will always deliver a valid string, even if is_string? is false. The objects stored in the value are converted to a string accordingly.

tag_id

Signature: *[const]* unsigned long **tag_id**

Description: Gets the tag ID if the value is a tagged value or 0 if not

Returns: The tag ID

See tag_id= for details about tagged values.

Tagged values have been added in version 0.24.

Python specific notes:
The object exposes a readable attribute 'tag_id'. This is the getter.

tag_id=

Signature: void **tag_id=** (unsigned long id)

Description: Sets the tag ID to make the value a tagged value or 0 to reset it

id: The tag ID

To get a tag ID, use RdbDatabase#user_tag_id (preferred) or RdbDatabase#tag_id (for internal use). Tagged values have been added in version 0.24. Tags can be given to identify a value, for example to attache measurement values to an item. To attach a value for a specific measurement, a tagged value can be used where the tag ID describes the measurement made. In that way, multiple values for different measurements can be attached to an item.

This variant has been introduced in version 0.24

Python specific notes:
The object exposes a writable attribute 'tag_id'. This is the setter.

text

Signature: *[const]* DText **text**

Description: Gets the text if the value represents one.

Returns: The DText object

This method has been introduced in version 0.22.

to_s

Signature: *[const]* string **to_s**

Description: Converts a value to a string

Returns: The string

The string can be used by the string constructor to create another object from it.

Python specific notes:
This method is also available as 'str(object)'.

4.193. API reference - Class RdbItem

Notation used in Ruby API documentation

Module: rdb

Description: An item inside the report database

An item is the basic information entity in the RDB. It is associated with a cell and a category. It can be assigned values which encapsulate other objects such as strings and geometrical objects. In addition, items can be assigned an image (i.e. a screenshot image) and tags which are basically boolean flags that can be defined freely.

Public constructors

new RdbItem ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**add_tag**	(unsigned long tag_id)	Adds a tag with the given id to the item
	void	**add_value**	(const RdbItemValue value)	Adds a value object to the values of this item
	void	**add_value**	(const DPolygon value)	Adds a polygon object to the values of this item
	void	**add_value**	(const DBox value)	Adds a box object to the values of this item
	void	**add_value**	(const DEdge value)	Adds an edge object to the values of this item
	void	**add_value**	(const DEdgePair value)	Adds an edge pair object to the values of this item
	void	**add_value**	(string value)	Adds a string object to the values of this item
	void	**add_value**	(double value)	Adds a numeric value to the values of this item

	void	add_value	(const Shape shape, const CplxTrans trans)	Adds a geometrical value object from a shape
	void	assign	(const RdbItem other)	Assigns another object to self
[const]	unsigned long	category_id		Gets the category ID
[const]	unsigned long	cell_id		Gets the cell ID
	void	clear_values		Removes all values from this item
[const]	const ReportDatabase ptr	database		Gets the database object that item is associated with
[const]	new RdbItem ptr	dup		Creates a copy of self
[const,iter]	RdbItemValue	each_value		Iterates over all values
[const]	bool	has_image?		Gets a value indicating that the item has an image attached
[const]	bool	has_tag?	(unsigned long tag_id)	Returns a value indicating whether the item has a tag with the given ID
[const]	QImage	image		Gets the attached image as a QImage object
	void	image=	(const QImage arg1)	Sets the attached image from a QImage object
[const]	string	image_str		Gets the image associated with this item as a string
	void	image_str=	(string image)	Sets the image from a string
[const]	bool	is_visited?		Gets a value indicating whether the item was already visited
	void	remove_tag	(unsigned long tag_id)	Remove the tag with the given id from the item
[const]	string	tags_str		Returns a string listing all tags of this item
	void	tags_str=	(string tags)	Sets the tags from a string

Deprecated methods (protected, public, static, non-static and constructors)

	void	create	Use of this method is deprecated. Use _create instead
	void	destroy	Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?	Use of this method is deprecated. Use _destroyed? instead

[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

add_tag

Signature: void **add_tag** (unsigned long tag_id)

Description: Adds a tag with the given id to the item

Each tag can be added once to the item. The tags of an item thus form a set. If a tag with that ID already exists, this method does nothing.

add_value

(1) Signature: void **add_value** (const RdbItemValue value)

Description: Adds a value object to the values of this item

value: The value to add.

(2) Signature: void **add_value** (const DPolygon value)

Description: Adds a polygon object to the values of this item

value: The polygon to add.

This method has been introduced in version 0.25 as a convenience method.

(3) Signature: void **add_value** (const DBox value)

Description: Adds a box object to the values of this item

value: The box to add.

This method has been introduced in version 0.25 as a convenience method.

(4) Signature: void **add_value** (const DEdge value)

Description: Adds an edge object to the values of this item

value: The edge to add.

This method has been introduced in version 0.25 as a convenience method.

(5) Signature: void **add_value** (const DEdgePair value)

Description: Adds an edge pair object to the values of this item

value: The edge pair to add.

This method has been introduced in version 0.25 as a convenience method.

(6) Signature: void **add_value** (string value)

Description: Adds a string object to the values of this item

value: The string to add.

This method has been introduced in version 0.25 as a convenience method.

(7) Signature: void **add_value** (double value)

Description: Adds a numeric value to the values of this item

value: The value to add.

This method has been introduced in version 0.25 as a convenience method.

(8) Signature: void **add_value** (const Shape shape, const CplxTrans trans)

Description: Adds a geometrical value object from a shape

value: The shape object from which to take the geometrical object.

trans: The transformation to apply.

The transformation can be used to convert database units to micron units.

This method has been introduced in version 0.25.3.

assign

Signature: void **assign** (const RdbItem other)

Description: Assigns another object to self

category_id

Signature: *[const]* unsigned long **category_id**

Description: Gets the category ID

Returns: The category ID

Returns the ID of the category that this item is associated with.

cell_id

Signature: *[const]* unsigned long **cell_id**

Description: Gets the cell ID

Returns: The cell ID

Returns the ID of the cell that this item is associated with.

clear_values

Signature: void **clear_values**

Description: Removes all values from this item

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

database

Signature: *[const]* const ReportDatabase ptr **database**

Description: Gets the database object that item is associated with

This method has been introduced in version 0.23.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new RdbItem ptr **dup**

Description: Creates a copy of self

Python specific notes:

This method also implements '__copy__' and '__deepcopy__'.

each_value

Signature: *[const,iter]* RdbItemValue **each_value**

Description: Iterates over all values

has_image?

Signature: *[const]* bool **has_image?**

Description: Gets a value indicating that the item has an image attached

See image_str how to obtain the image.

This method has been introduced in version 0.28.

has_tag?

Signature: *[const]* bool **has_tag?** (unsigned long tag_id)

Description: Returns a value indicating whether the item has a tag with the given ID

Returns: True, if the item has a tag with the given ID

image

Signature: *[const]* QImage **image**

Description: Gets the attached image as a QImage object

This method has been added in version 0.28.

Python specific notes:
The object exposes a readable attribute 'image'. This is the getter.

image=

Signature: void **image=** (const QImage arg1)

Description: Sets the attached image from a QImage object

This method has been added in version 0.28.

Python specific notes:
The object exposes a writable attribute 'image'. This is the setter.

image_str

Signature: *[const]* string **image_str**

Description: Gets the image associated with this item as a string

Returns: A base64-encoded image file (in PNG format)

Python specific notes:
The object exposes a readable attribute 'image_str'. This is the getter.

image_str=

Signature: void **image_str=** (string image)

Description: Sets the image from a string

image: A base64-encoded image file (preferably in PNG format)

Python specific notes:
The object exposes a writable attribute 'image_str'. This is the setter.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_visited?

Signature: *[const]* bool **is_visited?**

Description: Gets a value indicating whether the item was already visited

Returns: True, if the item has been visited already

new

Signature: *[static]* new RdbItem ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

remove_tag

Signature: void **remove_tag** (unsigned long tag_id)

Description: Remove the tag with the given id from the item

If a tag with that ID does not exists on this item, this method does nothing.

tags_str

Signature: *[const]* string **tags_str**

Description: Returns a string listing all tags of this item

Returns: A comma-separated list of tags

Python specific notes:
The object exposes a readable attribute 'tags_str'. This is the getter.

tags_str=

Signature: void **tags_str=** (string tags)

Description: Sets the tags from a string

tags: A comma-separated list of tags

Python specific notes:
The object exposes a writable attribute 'tags_str'. This is the setter.

4.194. API reference - Class ReportDatabase

Notation used in Ruby API documentation

Module: rdb

Description: The report database object

A report database is organized around a set of items which are associated with cells and categories. Categories can be organized hierarchically by created sub-categories of other categories. Cells are associated with layout database cells and can come with a example instantiation if the layout database does not allow a unique association of the cells. Items in the database can have a variety of attributes: values, tags and an image object. Values are geometrical objects for example. Tags are a set of boolean flags and an image can be attached to an item to provide a screenshot for visualization for example. This is the main report database object. The basic use case of this object is to create one inside a LayoutView and populate it with items, cell and categories or load it from a file. Another use case is to create a standalone ReportDatabase object and use the methods provided to perform queries or to populate it.

Public constructors

new ReportDatabase ptr	**new**	(string name)	Creates a report database

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	const RdbCategory ptr	**category_by_id**	(unsigned long id)	Gets a category by ID
	RdbCategory ptr	**category_by_id**	(unsigned long id)	Gets a category by ID (non-const version)
[const]	const RdbCategory ptr	**category_by_path**	(string path)	Gets a category by path
	RdbCategory ptr	**category_by_path**	(string path)	Gets a category by path (non-const version)
[const]	const RdbCell ptr	**cell_by_id**	(unsigned long id)	Returns the cell for a given ID
	RdbCell ptr	**cell_by_id**	(unsigned long id)	Returns the cell for a given ID (non-const version)
[const]	const RdbCell ptr	**cell_by_qname**	(string qname)	Returns the cell for a given qualified name

	RdbCell ptr	**cell_by_qname**	(string qname)	Returns the cell for a given qualified name (non-const version)
	RdbCategory ptr	**create_category**	(string name)	Creates a new top level category
	RdbCategory ptr	**create_category**	(RdbCategory ptr parent, string name)	Creates a new sub-category
	RdbCell ptr	**create_cell**	(string name)	Creates a new cell
	RdbCell ptr	**create_cell**	(string name, string variant)	Creates a new cell, potentially as a variant for a cell with the same name
	RdbItem ptr	**create_item**	(unsigned long cell_id, unsigned long category_id)	Creates a new item for the given cell/category combination
	RdbItem ptr	**create_item**	(RdbCell ptr cell, RdbCategory ptr category)	Creates a new item for the given cell/category combination
	void	**create_item**	(unsigned long cell_id, unsigned long category_id, const CplxTrans trans, const Shape shape, bool with_properties = true)	Creates a new item from a single shape
	void	**create_items**	(unsigned long cell_id, unsigned long category_id, const RecursiveShapeIterator iter, bool with_properties = true)	Creates new items from a shape iterator
	void	**create_items**	(unsigned long cell_id, unsigned long category_id, const CplxTrans trans, const Shapes shapes, bool with_properties = true)	Creates new items from a shape container
	void	**create_items**	(unsigned long cell_id, unsigned long category_id, const CplxTrans trans, Polygon[] array)	Creates new polygon items for the given cell/category combination
	void	**create_items**	(unsigned long cell_id, unsigned long category_id, const CplxTrans trans, Edge[] array)	Creates new edge items for the given cell/category combination

	void	**create_items**	(unsigned long cell_id, unsigned long category_id, const CplxTrans trans, EdgePair[] array)	Creates new edge pair items for the given cell/category combination
[const]	string	**description**		Gets the databases description
	void	**description=**	(string desc)	Sets the databases description
[const,iter]	RdbCategory	**each_category**		Iterates over all top-level categories
[iter]	RdbCategory	**each_category**		Iterates over all top-level categories (non-const version)
[const,iter]	RdbCell	**each_cell**		Iterates over all cells
[iter]	RdbCell	**each_cell**		Iterates over all cells (non-const version)
[const,iter]	RdbItem	**each_item**		Iterates over all items inside the database
[iter]	RdbItem	**each_item**		Iterates over all items inside the database (non-const version)
[const,iter]	RdbItem	**each_item_per_catego**	(unsigned long category_id)	Iterates over all items inside the database which are associated with the given category
[iter]	RdbItem	**each_item_per_category**	(unsigned long category_id)	Iterates over all items inside the database which are associated with the given category (non-const version)
[const,iter]	RdbItem	**each_item_per_cell**	(unsigned long cell_id)	Iterates over all items inside the database which are associated with the given cell
[iter]	RdbItem	**each_item_per_cell**	(unsigned long cell_id)	Iterates over all items inside the database which are associated with the given cell (non-const version)
[const,iter]	RdbItem	**each_item_per_cell_an**	(unsigned long cell_id, unsigned long category_id)	Iterates over all items inside the database which are associated with the given cell and category
[iter]	RdbItem	**each_item_per_cell_and**	(unsigned long cell_id, unsigned long category_id)	Iterates over all items inside the database which are associated with the given cell and category
[const]	string	**filename**		Gets the file name and path where the report database is stored
[const]	string	**generator**		Gets the databases generator
	void	**generator=**	(string generator)	Sets the generator string
[const]	bool	**is_modified?**		Returns a value indicating whether the database has been modified
	void	**load**	(string filename)	Loads the database from the given file

[const]	string	**name**		Gets the database name
[const]	unsigned long	**num_items**		Returns the number of items inside the database
[const]	unsigned long	**num_items**	(unsigned long cell_id, unsigned long category_id)	Returns the number of items inside the database for a given cell/category combination
[const]	unsigned long	**num_items_visited**		Returns the number of items already visited inside the database
[const]	unsigned long	**num_items_visited**	(unsigned long cell_id, unsigned long category_id)	Returns the number of items visited already for a given cell/category combination
[const]	string	**original_file**		Gets the original file name and path
	void	**original_file=**	(string path)	Sets the original file name and path
	void	**reset_modified**		Reset the modified flag
	void	**save**	(string filename)	Saves the database to the given file
	void	**set_item_visited**	(const RdbItem ptr item, bool visited)	Modifies the visited state of an item
	void	**set_tag_description**	(unsigned long tag_id, string description)	Sets the tag description for the given tag ID
[const]	string	**tag_description**	(unsigned long tag_id)	Gets the tag description for the given tag ID
[const]	unsigned long	**tag_id**	(string name)	Gets the tag ID for a given tag name
[const]	string	**tag_name**	(unsigned long tag_id)	Gets the tag name for the given tag ID
[const]	string	**top_cell_name**		Gets the top cell name
	void	**top_cell_name=**	(string cell_name)	Sets the top cell name string
[const]	unsigned long	**user_tag_id**	(string name)	Gets the tag ID for a given user tag name
	unsigned long[]	**variants**	(string name)	Gets the variants for a given cell name

Deprecated methods (protected, public, static, non-static and constructors)

void	**create**		Use of this method is deprecated. Use _create instead
void	**create_items**	(unsigned long cell_id, unsigned long category_id, const CplxTrans trans, const Region region)	Use of this method is deprecated
void	**create_items**	(unsigned long cell_id, unsigned long category_id,	Use of this method is deprecated

			const CplxTrans trans, const Edges edges)	
	void	create_items	(unsigned long cell_id, unsigned long category_id, const CplxTrans trans, const EdgePairs edge_pairs)	Use of this method is deprecated
	void	destroy		Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?		Use of this method is deprecated. Use _destroyed? instead
[const]	bool	is_const_object?		Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

category_by_id

(1) Signature: *[const]* const RdbCategory ptr **category_by_id** (unsigned long id)

Description: Gets a category by ID

Returns: The (const) category object or nil if the ID is not valid

(2) Signature: RdbCategory ptr **category_by_id** (unsigned long id)

Description: Gets a category by ID (non-const version)

Returns: The (const) category object or nil if the ID is not valid

This non-const variant has been introduced in version 0.29.

category_by_path

(1) Signature: *[const]* const RdbCategory ptr **category_by_path** (string path)

Description: Gets a category by path

path: The full path to the category starting from the top level (subcategories separated by dots)

Returns: The (const) category object or nil if the name is not valid

(2) Signature: RdbCategory ptr **category_by_path** (string path)

Description: Gets a category by path (non-const version)

path: The full path to the category starting from the top level (subcategories separated by dots)

Returns: The (const) category object or nil if the name is not valid

This non-const variant has been introduced in version 0.29.

cell_by_id

(1) Signature: *[const]* const RdbCell ptr **cell_by_id** (unsigned long id)

Description: Returns the cell for a given ID

id: The ID of the cell

Returns: The cell object or nil if no cell with that ID exists

(2) Signature: RdbCell ptr **cell_by_id** (unsigned long id)

Description: Returns the cell for a given ID (non-const version)

id: The ID of the cell

Returns: The cell object or nil if no cell with that ID exists

This non-const variant has been added version 0.29.

cell_by_qname

(1) Signature: *[const]* const RdbCell ptr **cell_by_qname** (string qname)

Description: Returns the cell for a given qualified name

qname:	The qualified name of the cell (name plus variant name optionally)
Returns:	The cell object or nil if no such cell exists

(2) Signature: RdbCell ptr **cell_by_qname** (string qname)

Description: Returns the cell for a given qualified name (non-const version)

qname:	The qualified name of the cell (name plus variant name optionally)
Returns:	The cell object or nil if no such cell exists

This non-const variant has been added version 0.29.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

create_category

(1) Signature: RdbCategory ptr **create_category** (string name)

Description: Creates a new top level category

name:	The name of the category

(2) Signature: RdbCategory ptr **create_category** (RdbCategory ptr parent, string name)

Description: Creates a new sub-category

parent:	The category under which the category should be created
name:	The name of the category

create_cell

(1) Signature: RdbCell ptr **create_cell** (string name)

Description: Creates a new cell

name:	The name of the cell

(2) Signature: RdbCell ptr **create_cell** (string name, string variant)

Description: Creates a new cell, potentially as a variant for a cell with the same name

name:	The name of the cell
variant:	The variant name of the cell

create_item

(1) Signature: RdbItem ptr **create_item** (unsigned long cell_id, unsigned long category_id)

Description: Creates a new item for the given cell/category combination

cell_id:	The ID of the cell to which the item is associated
category_id:	The ID of the category to which the item is associated

A more convenient method that takes cell and category objects instead of ID's is the other version of create_item.

(2) Signature: RdbItem ptr **create_item** (RdbCell ptr cell, RdbCategory ptr category)

Description: Creates a new item for the given cell/category combination

cell:	The cell to which the item is associated
category:	The category to which the item is associated

This convenience method has been added in version 0.25.

(3) Signature: void **create_item** (unsigned long cell_id, unsigned long category_id, const CplxTrans trans, const Shape shape, bool with_properties = true)

Description: Creates a new item from a single shape

cell_id:	The ID of the cell to which the item is associated
category_id:	The ID of the category to which the item is associated
shape:	The shape to take the geometrical object from
trans:	The transformation to apply
with_properties:	If true, user properties will be turned into tagged values as well

This method produces an item from the given shape. It accepts various kind of shapes, such as texts, polygons, boxes and paths and converts them to a corresponding item. The transformation argument can be used to supply the transformation that applies the database unit for example.

This method has been introduced in version 0.25.3. The 'with_properties' argument has been added in version 0.28.

create_items

(1) Signature: void **create_items** (unsigned long cell_id, unsigned long category_id, const RecursiveShapeIterator iter, bool with_properties = true)

Description: Creates new items from a shape iterator

cell_id:	The ID of the cell to which the item is associated
category_id:	The ID of the category to which the item is associated
iter:	The iterator (a RecursiveShapeIterator object) from which to take the items
with_properties:	If true, user properties will be turned into tagged values as well

This method takes the shapes from the given iterator and produces items from them. It accepts various kind of shapes, such as texts, polygons, boxes and paths and converts them to corresponding items. This method will produce a flat version of the shapes iterated by the shape iterator. A similar method, which is intended for production of polygon or edge error layers and also provides hierarchical database construction is RdbCategory#scan_shapes.

This method has been introduced in version 0.25.3. The 'with_properties' argument has been added in version 0.28.

(2) Signature: void **create_items** (unsigned long cell_id, unsigned long category_id, const CplxTrans trans, const Shapes shapes, bool with_properties = true)

Description: Creates new items from a shape container

cell_id:	The ID of the cell to which the item is associated
category_id:	The ID of the category to which the item is associated
shapes:	The shape container from which to take the items

trans:	The transformation to apply
with_properties:	If true, user properties will be turned into tagged values as well

This method takes the shapes from the given container and produces items from them. It accepts various kind of shapes, such as texts, polygons, boxes and paths and converts them to corresponding items. The transformation argument can be used to supply the transformation that applies the database unit for example.

This method has been introduced in version 0.25.3. The 'with_properties' argument has been added in version 0.28.

(3) Signature: void **create_items** (unsigned long cell_id, unsigned long category_id, const CplxTrans trans, const Region region)

Description: Creates new polygon items for the given cell/category combination

cell_id:	The ID of the cell to which the item is associated
category_id:	The ID of the category to which the item is associated
trans:	The transformation to apply
region:	The region (a Region object) containing the polygons for which to create items

Use of this method is deprecated

For each polygon in the region a single item will be created. The value of the item will be this polygon. A transformation can be supplied which can be used for example to convert the object's dimensions to micron units by scaling by the database unit.

This method will also produce a flat version of the shapes inside the region. RdbCategory#scan_collection is a similar method which also supports construction of hierarchical databases from deep regions.

This method has been introduced in version 0.23. It has been deprecated in favor of RdbCategory#scan_collection in version 0.28.

(4) Signature: void **create_items** (unsigned long cell_id, unsigned long category_id, const CplxTrans trans, const Edges edges)

Description: Creates new edge items for the given cell/category combination

cell_id:	The ID of the cell to which the item is associated
category_id:	The ID of the category to which the item is associated
trans:	The transformation to apply
edges:	The list of edges (an Edges object) for which the items are created

Use of this method is deprecated

For each edge a single item will be created. The value of the item will be this edge. A transformation can be supplied which can be used for example to convert the object's dimensions to micron units by scaling by the database unit.

This method will also produce a flat version of the edges inside the edge collection. RdbCategory#scan_collection is a similar method which also supports construction of hierarchical databases from deep edge collections.

This method has been introduced in version 0.23. It has been deprecated in favor of RdbCategory#scan_collection in version 0.28.

(5) Signature: void **create_items** (unsigned long cell_id, unsigned long category_id, const CplxTrans trans, const EdgePairs edge_pairs)

Description: Creates new edge pair items for the given cell/category combination

cell_id:	The ID of the cell to which the item is associated
category_id:	The ID of the category to which the item is associated
trans:	The transformation to apply
edges:	The list of edge pairs (an EdgePairs object) for which the items are created

Use of this method is deprecated

For each edge pair a single item will be created. The value of the item will be this edge pair. A transformation can be supplied which can be used for example to convert the object's dimensions to micron units by scaling by the database unit.

This method will also produce a flat version of the edge pairs inside the edge pair collection. RdbCategory#scan_collection is a similar method which also supports construction of hierarchical databases from deep edge pair collections.

This method has been introduced in version 0.23. It has been deprecated in favor of RdbCategory#scan_collection in version 0.28.

(6) Signature: void **create_items** (unsigned long cell_id, unsigned long category_id, const CplxTrans trans, Polygon[] array)

Description: Creates new polygon items for the given cell/category combination

cell_id:	The ID of the cell to which the item is associated
category_id:	The ID of the category to which the item is associated
trans:	The transformation to apply
polygons:	The list of polygons for which the items are created

For each polygon a single item will be created. The value of the item will be this polygon. A transformation can be supplied which can be used for example to convert the object's dimensions to micron units by scaling by the database unit.

This method has been introduced in version 0.23.

(7) Signature: void **create_items** (unsigned long cell_id, unsigned long category_id, const CplxTrans trans, Edge[] array)

Description: Creates new edge items for the given cell/category combination

cell_id:	The ID of the cell to which the item is associated
category_id:	The ID of the category to which the item is associated
trans:	The transformation to apply
edges:	The list of edges for which the items are created

For each edge a single item will be created. The value of the item will be this edge. A transformation can be supplied which can be used for example to convert the object's dimensions to micron units by scaling by the database unit.

This method has been introduced in version 0.23.

(8) Signature: void **create_items** (unsigned long cell_id, unsigned long category_id, const CplxTrans trans, EdgePair[] array)

Description: Creates new edge pair items for the given cell/category combination

cell_id:	The ID of the cell to which the item is associated
category_id:	The ID of the category to which the item is associated
trans:	The transformation to apply
edge_pairs:	The list of edge_pairs for which the items are created

For each edge pair a single item will be created. The value of the item will be this edge pair. A transformation can be supplied which can be used for example to convert the object's dimensions to micron units by scaling by the database unit.

This method has been introduced in version 0.23.

description

Signature: *[const]* string **description**

Description: Gets the databases description

Returns: The description string

The description is a general purpose string that is supposed to further describe the database and its content in a human-readable form.

Python specific notes:
The object exposes a readable attribute 'description'. This is the getter.

description=

Signature: void **description=** (string desc)

Description: Sets the databases description

desc: The description string

Python specific notes:
The object exposes a writable attribute 'description'. This is the setter.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

each_category

(1) Signature: *[const,iter]* RdbCategory **each_category**

Description: Iterates over all top-level categories

(2) Signature: *[iter]* RdbCategory **each_category**

Description: Iterates over all top-level categories (non-const version)

The non-const variant has been added in version 0.29.

each_cell

(1) Signature: *[const,iter]* RdbCell **each_cell**

Description: Iterates over all cells

(2) Signature: *[iter]* RdbCell **each_cell**

Description: Iterates over all cells (non-const version)

This non-const variant has been added version 0.29.

each_item

(1) Signature: *[const,iter]* RdbItem **each_item**

Description: Iterates over all items inside the database

(2) Signature: *[iter]* RdbItem **each_item**

Description: Iterates over all items inside the database (non-const version)

This non-const variant has been added in version 0.29.

each_item_per_category

(1) Signature: *[const,iter]* RdbItem **each_item_per_category** (unsigned long category_id)

Description: Iterates over all items inside the database which are associated with the given category

category_id: The ID of the category for which all associated items should be retrieved

(2) Signature: *[iter]* RdbItem **each_item_per_category** (unsigned long category_id)

Description: Iterates over all items inside the database which are associated with the given category (non-const version)

category_id: The ID of the category for which all associated items should be retrieved

This non-const variant has been added in version 0.29.

each_item_per_cell

(1) Signature: *[const,iter]* RdbItem **each_item_per_cell** (unsigned long cell_id)

Description: Iterates over all items inside the database which are associated with the given cell

cell_id: The ID of the cell for which all associated items should be retrieved

(2) Signature: *[iter]* RdbItem **each_item_per_cell** (unsigned long cell_id)

Description: Iterates over all items inside the database which are associated with the given cell (non-const version)

cell_id: The ID of the cell for which all associated items should be retrieved

This non-const variant has been added in version 0.29.

each_item_per_cell_and_category

(1) Signature: *[const,iter]* RdbItem **each_item_per_cell_and_category** (unsigned long cell_id, unsigned long category_id)

Description: Iterates over all items inside the database which are associated with the given cell and category

cell_id: The ID of the cell for which all associated items should be retrieved

category_id: The ID of the category for which all associated items should be retrieved

(2) Signature: *[iter]* RdbItem **each_item_per_cell_and_category** (unsigned long cell_id, unsigned long category_id)

Description: Iterates over all items inside the database which are associated with the given cell and category

cell_id: The ID of the cell for which all associated items should be retrieved

category_id: The ID of the category for which all associated items should be retrieved

This non-const variant has been added in version 0.29.

filename

Signature: *[const]* string **filename**

Description: Gets the file name and path where the report database is stored

Returns: The file name and path

This property is set when a database is saved or loaded. It cannot be set manually.

generator

Signature: *[const]* string **generator**

Description: Gets the databases generator

Returns: The generator string

The generator string describes how the database was created, i.e. DRC tool name and tool options. In a later version this will allow re-running the tool that created the report.

Python specific notes:
The object exposes a readable attribute 'generator'. This is the getter.

generator=

Signature: void **generator=** (string generator)

Description: Sets the generator string

generator: The generator string

Python specific notes:
The object exposes a writable attribute 'generator'. This is the setter.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_modified?

Signature: *[const]* bool **is_modified?**

Description: Returns a value indicating whether the database has been modified

load

Signature: void **load** (string filename)

Description: Loads the database from the given file

filename: The file from which to load the database

The reader recognizes the format automatically and will choose the appropriate decoder. 'gzip' compressed files are uncompressed automatically.

name

Signature: *[const]* string **name**

Description: Gets the database name

Returns: The database name

The name of the database is supposed to identify the database within a layout view context. The name is modified to be unique when a database is entered into a layout view.

new

Signature: *[static]* new ReportDatabase ptr **new** (string name)

Description: Creates a report database

name: The name of the database

The name of the database will be used in the user interface to refer to a certain database.

Python specific notes:
This method is the default initializer of the object.

num_items

(1) Signature: *[const]* unsigned long **num_items**

Description: Returns the number of items inside the database

Returns: The total number of items

(2) Signature: *[const]* unsigned long **num_items** (unsigned long cell_id, unsigned long category_id)

Description: Returns the number of items inside the database for a given cell/category combination

cell_id: The ID of the cell for which to retrieve the number

category_id: The ID of the category for which to retrieve the number

Returns: The total number of items for the given cell and the given category

num_items_visited

(1) Signature: *[const]* unsigned long **num_items_visited**

Description: Returns the number of items already visited inside the database

Returns: The total number of items already visited

(2) Signature: *[const]* unsigned long **num_items_visited** (unsigned long cell_id, unsigned long category_id)

Description: Returns the number of items visited already for a given cell/category combination

cell_id: The ID of the cell for which to retrieve the number

category_id: The ID of the category for which to retrieve the number

Returns: The total number of items visited for the given cell and the given category

original_file

Signature: *[const]* string **original_file**

Description: Gets the original file name and path

Returns: The original file name and path

The original file name is supposed to describe the file from which this report database was generated.

Python specific notes:
The object exposes a readable attribute 'original_file'. This is the getter.

original_file=

Signature: void **original_file=** (string path)

Description: Sets the original file name and path

path: The path

Python specific notes:

The object exposes a writable attribute 'original_file'. This is the setter.

reset_modified

Signature: void **reset_modified**

Description: Reset the modified flag

save

Signature: void **save** (string filename)

Description: Saves the database to the given file

filename: The file to which to save the database

The database is always saved in KLayout's XML-based format.

set_item_visited

Signature: void **set_item_visited** (const RdbItem ptr item, bool visited)

Description: Modifies the visited state of an item

item: The item to modify

visited: True to set the item to visited state, false otherwise

set_tag_description

Signature: void **set_tag_description** (unsigned long tag_id, string description)

Description: Sets the tag description for the given tag ID

tag_id: The ID of the tag

description: The description string

See tag_id for a details about tags.

tag_description

Signature: *[const]* string **tag_description** (unsigned long tag_id)

Description: Gets the tag description for the given tag ID

tag_id: The ID of the tag

Returns: The description string

See tag_id for a details about tags.

tag_id

Signature: *[const]* unsigned long **tag_id** (string name)

Description: Gets the tag ID for a given tag name

name: The tag name

Returns: The corresponding tag ID

Tags are used to tag items in the database and to specify tagged (named) values. This method will always succeed and the tag will be created if it does not exist yet. Tags are basically names. There are user tags (for free assignment) and system tags which are used within the system. Both are separated to avoid name clashes.

tag_id handles system tags while user_tag_id handles user tags.

tag_name

Signature: *[const]* string **tag_name** (unsigned long tag_id)

Description: Gets the tag name for the given tag ID

tag_id: The ID of the tag

Returns: The name of the tag

See tag_id for a details about tags.

This method has been introduced in version 0.24.10.

top_cell_name

Signature: *[const]* string **top_cell_name**

Description: Gets the top cell name

Returns: The top cell name

The top cell name identifies the top cell of the design for which the report was generated. This property must be set to establish a proper hierarchical context for a hierarchical report database.

Python specific notes:
The object exposes a readable attribute 'top_cell_name'. This is the getter.

top_cell_name=

Signature: void **top_cell_name=** (string cell_name)

Description: Sets the top cell name string

cell_name: The top cell name

Python specific notes:
The object exposes a writable attribute 'top_cell_name'. This is the setter.

user_tag_id

Signature: *[const]* unsigned long **user_tag_id** (string name)

Description: Gets the tag ID for a given user tag name

name: The user tag name

Returns: The corresponding tag ID

This method will always succeed and the tag will be created if it does not exist yet. See tag_id for a details about tags.

This method has been added in version 0.24.

variants

Signature: unsigned long[] **variants** (string name)

Description: Gets the variants for a given cell name

name: The basic name of the cell

Returns: An array of ID's representing cells that are variants for the given base name

4.195. API reference - Class LayerProperties

Notation used in Ruby API documentation

Module: lay

Description: The layer properties structure

The layer properties encapsulate the settings relevant for the display and source of a layer.

Each attribute is present in two incarnations: local and real. "real" refers to the effective attribute after collecting the attributes from the parents to the leaf property node. In the spirit of this distinction, all read accessors are present in "local" and "real" form. The read accessors take a boolean parameter "real" that must be set to true, if the real value shall be returned.

"brightness" is a index that indicates how much to make the color brighter to darker rendering the effective color (eff_frame_color, eff_fill_color). It's value is roughly between -255 and 255.

Public constructors

new LayerProperties ptr	**new**		Creates a new object of this class

Public methods

[const]	bool	**!=**	(const LayerProperties other)	Inequality
[const]	bool	**==**	(const LayerProperties other)	Equality
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	int	**animation**	(bool real)	Gets the animation state
[const]	int	**animation**		Gets the animation state
	void	**animation=**	(int animation)	Sets the animation state
	void	**assign**	(const LayerProperties other)	Assigns another object to self
[const]	int	**cellview**		Gets the the cellview index

	void	clear_dither_pattern		Clears the dither pattern
	void	clear_fill_color		Resets the fill color
	void	clear_frame_color		Resets the frame color
	void	clear_line_style		Clears the line style
	void	clear_lower_hier_level		Clears the lower hierarchy level specification
	void	clear_source_name		Removes any stream layer name specification from this layer
	void	clear_upper_hier_level		Clears the upper hierarchy level specification
[const]	int	dither_pattern	(bool real)	Gets the dither pattern index
[const]	int	dither_pattern		Gets the dither pattern index
	void	dither_pattern=	(int index)	Sets the dither pattern index
[const]	new LayerProperties ptr	dup		Creates a copy of self
[const]	unsigned int	eff_dither_pattern	(bool real)	Gets the effective dither pattern index
[const]	unsigned int	eff_dither_pattern		Gets the effective dither pattern index
[const]	unsigned int	eff_fill_color	(bool real)	Gets the effective fill color
[const]	unsigned int	eff_fill_color		Gets the effective fill color
[const]	unsigned int	eff_frame_color	(bool real)	Gets the effective frame color
[const]	unsigned int	eff_frame_color		Gets the effective frame color
[const]	unsigned int	eff_line_style	(bool real)	Gets the effective line style index
[const]	unsigned int	eff_line_style		Gets the line style index
[const]	int	fill_brightness	(bool real)	Gets the fill brightness value
[const]	int	fill_brightness		Gets the fill brightness value
	void	fill_brightness=	(int brightness)	Sets the fill brightness
[const]	unsigned int	fill_color	(bool real)	Gets the fill color
[const]	unsigned int	fill_color		Gets the fill color
	void	fill_color=	(unsigned int color)	Sets the fill color to the given value
[const]	LayerProperties	flat		Returns the "flattened" (effective) layer properties entry for this node

[const]	int	**frame_brightness**	(bool real)	Gets the frame brightness value
[const]	int	**frame_brightness**		Gets the frame brightness value
	void	**frame_brightness=**	(int brightness)	Sets the frame brightness
[const]	unsigned int	**frame_color**	(bool real)	Gets the frame color
[const]	unsigned int	**frame_color**		Gets the frame color
	void	**frame_color=**	(unsigned int color)	Sets the frame color to the given value
[const]	bool	**has_dither_pattern?**	(bool real)	True, if the dither pattern is set
[const]	bool	**has_dither_pattern?**		True, if the dither pattern is set
[const]	bool	**has_fill_color?**	(bool real)	True, if the fill color is set
[const]	bool	**has_fill_color?**		True, if the fill color is set
[const]	bool	**has_frame_color?**	(bool real)	True, if the frame color is set
[const]	bool	**has_frame_color?**		True, if the frame color is set
[const]	bool	**has_line_style?**	(bool real)	Gets a value indicating whether the line style is set
[const]	bool	**has_line_style?**		True, if the line style is set
[const]	bool	**has_lower_hier_level?**	(bool real)	Gets a value indicating whether a lower hierarchy level is explicitly specified
[const]	bool	**has_lower_hier_level?**		Gets a value indicating whether a lower hierarchy level is explicitly specified
[const]	bool	**has_source_name?**	(bool real)	Gets a value indicating whether a stream layer name is specified for this layer
[const]	bool	**has_source_name?**		Gets a value indicating whether a stream layer name is specified for this layer
[const]	bool	**has_upper_hier_level?**	(bool real)	Gets a value indicating whether an upper hierarchy level is explicitly specified
[const]	bool	**has_upper_hier_level?**		Gets a value indicating whether an upper hierarchy level is explicitly specified
[const]	int	**layer_index**		Gets the the layer index
[const]	int	**line_style**	(bool real)	Gets the line style index
[const]	int	**line_style**		Gets the line style index
	void	**line_style=**	(int index)	Sets the line style index
[const]	int	**lower_hier_level**	(bool real)	Gets the lower hierarchy level shown

[const]	int	**lower_hier_level**		Gets the lower hierarchy level shown
	void	**lower_hier_level=**	(int level)	Sets the lower hierarchy level
[const]	int	**lower_hier_level_mode**	(bool real)	Gets the mode for the lower hierarchy level.
[const]	int	**lower_hier_level_mode**		Gets the mode for the lower hierarchy level.
[const]	bool	**lower_hier_level_relative?**	(bool real)	Gets a value indicating whether the lower hierarchy level is relative.
[const]	bool	**lower_hier_level_relative?**		Gets a value indicating whether the upper hierarchy level is relative.
	void	**marked=**	(bool marked)	Sets the marked state
[const]	bool	**marked?**	(bool real)	Gets the marked state
[const]	bool	**marked?**		Gets the marked state
[const]	string	**name**		Gets the name
	void	**name=**	(string name)	Sets the name to the given string
	void	**set_lower_hier_level**	(int level, bool relative)	Sets the lower hierarchy level and if it is relative to the context cell
	void	**set_lower_hier_level**	(int level, bool relative, int mode)	Sets the lower hierarchy level, whether it is relative to the context cell and the mode
	void	**set_upper_hier_level**	(int level, bool relative)	Sets the upper hierarchy level and if it is relative to the context cell
	void	**set_upper_hier_level**	(int level, bool relative, int mode)	Sets the upper hierarchy level, if it is relative to the context cell and the mode
[const]	string	**source**	(bool real)	Gets the source specification
[const]	string	**source**		Gets the source specification
	void	**source=**	(string s)	Loads the source specification from a string
[const]	int	**source_cellview**	(bool real)	Gets the cellview index that this layer refers to
[const]	int	**source_cellview**		Gets the cellview index that this layer refers to
	void	**source_cellview=**	(int cellview_index)	Sets the cellview index that this layer refers to
[const]	int	**source_datatype**	(bool real)	Gets the stream datatype that the shapes are taken from
[const]	int	**source_datatype**		Gets the stream datatype that the shapes are taken from

	void	source_datatype=	(int datatype)	Sets the stream datatype that the shapes are taken from
[const]	int	source_layer	(bool real)	Gets the stream layer that the shapes are taken from
[const]	int	source_layer		Gets the stream layer that the shapes are taken from
	void	source_layer=	(int layer)	Sets the stream layer that the shapes are taken from
[const]	int	source_layer_index	(bool real)	Gets the layer index that the shapes are taken from
[const]	int	source_layer_index		Gets the stream layer that the shapes are taken from
	void	source_layer_index=	(int index)	Sets the layer index specification that the shapes are taken from
[const]	string	source_name	(bool real)	Gets the stream name that the shapes are taken from
[const]	string	source_name		Gets the stream name that the shapes are taken from
	void	source_name=	(string name)	Sets the stream layer name that the shapes are taken from
[const]	DCplxTrans[]	trans	(bool real)	Gets the transformations that the layer is transformed with
[const]	DCplxTrans[]	trans		Gets the transformations that the layer is transformed with
	void	trans=	(DCplxTrans[] trans_vector)	Sets the transformations that the layer is transformed with
	void	transparent=	(bool transparent)	Sets the transparency state
[const]	bool	transparent?	(bool real)	Gets the transparency state
[const]	bool	transparent?		Gets the transparency state
[const]	int	upper_hier_level	(bool real)	Gets the upper hierarchy level shown
[const]	int	upper_hier_level		Gets the upper hierarchy level shown
	void	upper_hier_level=	(int level)	Sets a upper hierarchy level
[const]	int	upper_hier_level_mode	(bool real)	Gets the mode for the upper hierarchy level.
[const]	int	upper_hier_level_mode		Gets the mode for the upper hierarchy level.

[const]	bool	**upper_hier_level_relative?**	(bool real)	Gets a value indicating whether if the upper hierarchy level is relative.
[const]	bool	**upper_hier_level_relative?**		Gets a value indicating whether the upper hierarchy level is relative.
	void	**valid=**	(bool valid)	Sets the validity state
[const]	bool	**valid?**	(bool real)	Gets the validity state
[const]	bool	**valid?**		Gets the validity state
	void	**visible=**	(bool visible)	Sets the visibility state
[const]	bool	**visible?**	(bool real)	Gets the visibility state
[const]	bool	**visible?**		Gets the visibility state
[const]	int	**width**	(bool real)	Gets the line width
[const]	int	**width**		Gets the line width
	void	**width=**	(int width)	Sets the line width to the given width
	void	**xfill=**	(bool xfill)	Sets a value indicating whether shapes are drawn with a cross
[const]	bool	**xfill?**	(bool real)	Gets a value indicating whether shapes are drawn with a cross
[const]	bool	**xfill?**		Gets a value indicating whether shapes are drawn with a cross

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**		Use of this method is deprecated. Use _create instead
	void	**destroy**		Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**		Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**		Use of this method is deprecated. Use _is_const_object? instead
[const]	bool	**lower_hier_level_relative**	(bool real)	Use of this method is deprecated. Use lower_hier_level_relative? instead
[const]	bool	**lower_hier_level_relative**		Use of this method is deprecated. Use lower_hier_level_relative? instead
[const]	bool	**upper_hier_level_relative**	(bool real)	Use of this method is deprecated. Use upper_hier_level_relative? instead

[const]	bool	**upper_hier_level_relative**	Use of this method is deprecated. Use upper_hier_level_relative? instead

Detailed description

!=

Signature: *[const]* bool **!=** (const LayerProperties other)

Description: Inequality

other: The other object to compare against

==

Signature: *[const]* bool **==** (const LayerProperties other)

Description: Equality

other: The other object to compare against

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

animation

(1) Signature: *[const]* int **animation** (bool real)

Description: Gets the animation state

The animation state is an integer either being 0 (static), 1 (scrolling), 2 (blinking) or 3 (inversely blinking)

Python specific notes:
This method is available as 'animation_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* int **animation**

Description: Gets the animation state

This method is a convenience method for "animation(true)"

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'animation'. This is the getter.

animation=

Signature: void **animation=** (int animation)

Description: Sets the animation state

See the description of the animation method for details about the animation state

Python specific notes:
The object exposes a writable attribute 'animation'. This is the setter.

assign

Signature: void **assign** (const LayerProperties other)

Description: Assigns another object to self

cellview

Signature: *[const]* int **cellview**

Description: Gets the the cellview index

This is the index of the actual cellview to use. Basically, this method returns source_cellview in "real" mode. The result may be different, if the cellview is not valid for example. In this case, a negative value is returned.

clear_dither_pattern

Signature: void **clear_dither_pattern**

Description: Clears the dither pattern

clear_fill_color

Signature: void **clear_fill_color**

Description: Resets the fill color

clear_frame_color

Signature: void **clear_frame_color**

Description: Resets the frame color

clear_line_style

Signature: void **clear_line_style**

Description: Clears the line style

This method has been introduced in version 0.25.

clear_lower_hier_level

Signature: void **clear_lower_hier_level**

Description: Clears the lower hierarchy level specification

See has_lower_hier_level for a description of this property

clear_source_name

Signature: void **clear_source_name**

Description: Removes any stream layer name specification from this layer

clear_upper_hier_level

Signature: void **clear_upper_hier_level**

Description: Clears the upper hierarchy level specification

See has_upper_hier_level for a description of this property

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dither_pattern

(1) Signature: *[const]* int **dither_pattern** (bool real)

Description: Gets the dither pattern index

real: Set to true to return the real instead of local value

This method may deliver an invalid dither pattern index if it is not set.

Python specific notes:
This method is available as 'dither_pattern_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* int **dither_pattern**

Description: Gets the dither pattern index

This method is a convenience method for "dither_pattern(true)"

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'dither_pattern'. This is the getter.

dither_pattern=

Signature: void **dither_pattern=** (int index)

Description: Sets the dither pattern index

The dither pattern index must be one of the valid indices. The first indices are reserved for built-in pattern, the following ones are custom pattern. Index 0 is always solid filled and 1 is always the hollow filled pattern. For custom pattern see LayoutView#add_stipple.

Python specific notes:
The object exposes a writable attribute 'dither_pattern'. This is the setter.

dup

Signature: *[const]* new LayerProperties ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

eff_dither_pattern

(1) Signature: *[const]* unsigned int **eff_dither_pattern** (bool real)

Description: Gets the effective dither pattern index

real: Set to true to return the real instead of local value

The effective dither pattern index is always a valid index, even if no dither pattern is set.

(2) Signature: *[const]* unsigned int **eff_dither_pattern**

Description: Gets the effective dither pattern index

This method is a convenience method for "eff_dither_pattern(true)"

This method has been introduced in version 0.22.

eff_fill_color

(1) Signature: *[const]* unsigned int **eff_fill_color** (bool real)

Description: Gets the effective fill color

real: Set to true to return the real instead of local value

The effective fill color is computed from the frame color brightness and the frame color.

(2) Signature: *[const]* unsigned int **eff_fill_color**

Description: Gets the effective fill color

This method is a convenience method for "eff_fill_color(true)"

This method has been introduced in version 0.22.

eff_frame_color

(1) Signature: *[const]* unsigned int **eff_frame_color** (bool real)

Description: Gets the effective frame color

real: Set to true to return the real instead of local value

The effective frame color is computed from the frame color brightness and the frame color.

(2) Signature: *[const]* unsigned int **eff_frame_color**

Description: Gets the effective frame color

This method is a convenience method for "eff_frame_color(true)"

This method has been introduced in version 0.22.

eff_line_style

(1) Signature: *[const]* unsigned int **eff_line_style** (bool real)

Description: Gets the effective line style index

real: Set to true to return the real instead of local value

The effective line style index is always a valid index, even if no line style is set. In that case, a default style index will be returned.

This method has been introduced in version 0.25.

(2) Signature: *[const]* unsigned int **eff_line_style**

Description: Gets the line style index

This method is a convenience method for "eff_line_style(true)"

This method has been introduced in version 0.25.

fill_brightness

(1) Signature: *[const]* int **fill_brightness** (bool real)

Description: Gets the fill brightness value

real: Set to true to return the real instead of local value

If the brightness is not set, this method may return an invalid value

Python specific notes:
This method is available as 'fill_brightness_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* int **fill_brightness**

Description: Gets the fill brightness value

This method is a convenience method for "fill_brightness(true)"

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'fill_brightness'. This is the getter.

fill_brightness=

Signature: void **fill_brightness=** (int brightness)

Description: Sets the fill brightness

For neutral brightness set this value to 0. For darker colors set it to a negative value (down to -255), for brighter colors to a positive value (up to 255)

Python specific notes:
The object exposes a writable attribute 'fill_brightness'. This is the setter.

fill_color

(1) Signature: *[const]* unsigned int **fill_color** (bool real)

Description: Gets the fill color

real: Set to true to return the real instead of local value

This method may return an invalid color if the color is not set.

Python specific notes:
This method is available as 'fill_color_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* unsigned int **fill_color**

Description: Gets the fill color

This method is a convenience method for "fill_color(true)"

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'fill_color'. This is the getter.

fill_color=

Signature: void **fill_color=** (unsigned int color)

Description: Sets the fill color to the given value

The color is a 32bit value encoding the blue value in the lower 8 bits, the green value in the next 8 bits and the red value in the 8 bits above that.

Python specific notes:
The object exposes a writable attribute 'fill_color'. This is the setter.

flat

Signature: *[const]* LayerProperties **flat**

Description: Returns the "flattened" (effective) layer properties entry for this node

This method returns a LayerProperties object that is not embedded into a hierarchy. This object represents the effective layer properties for the given node. In particular, all 'local' properties are identical to the 'real' properties. Such an object can be used as a basis for manipulations. This method has been introduced in version 0.22.

frame_brightness

(1) Signature: *[const]* int **frame_brightness** (bool real)

Description: Gets the frame brightness value

real: Set to true to return the real instead of local value

If the brightness is not set, this method may return an invalid value

Python specific notes:
This method is available as 'frame_brightness_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* int **frame_brightness**

Description: Gets the frame brightness value

This method is a convenience method for "frame_brightness(true)"

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'frame_brightness'. This is the getter.

frame_brightness=

Signature: void **frame_brightness=** (int brightness)

Description: Sets the frame brightness

For neutral brightness set this value to 0. For darker colors set it to a negative value (down to -255), for brighter colors to a positive value (up to 255)

Python specific notes:
The object exposes a writable attribute 'frame_brightness'. This is the setter.

frame_color

(1) Signature: *[const]* unsigned int **frame_color** (bool real)

Description: Gets the frame color

real: Set to true to return the real instead of local value

This method may return an invalid color if the color is not set.

Python specific notes:
This method is available as 'frame_color_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* unsigned int **frame_color**

Description: Gets the frame color

This method is a convenience method for "frame_color(true)"

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'frame_color'. This is the getter.

frame_color=

Signature: void **frame_color=** (unsigned int color)

Description: Sets the frame color to the given value

The color is a 32bit value encoding the blue value in the lower 8 bits, the green value in the next 8 bits and the red value in the 8 bits above that.

Python specific notes:
The object exposes a writable attribute 'frame_color'. This is the setter.

has_dither_pattern?

(1) Signature: *[const]* bool **has_dither_pattern?** (bool real)

Description: True, if the dither pattern is set

(2) Signature: *[const]* bool **has_dither_pattern?**

Description: True, if the dither pattern is set

This method is a convenience method for "has_dither_pattern?(true)"

This method has been introduced in version 0.22.

has_fill_color?

(1) Signature: *[const]* bool **has_fill_color?** (bool real)

Description: True, if the fill color is set

(2) Signature: *[const]* bool **has_fill_color?**

Description: True, if the fill color is set

This method is a convenience method for "has_fill_color?(true)"

This method has been introduced in version 0.22.

has_frame_color?

(1) Signature: *[const]* bool **has_frame_color?** (bool real)

Description: True, if the frame color is set

(2) Signature: *[const]* bool **has_frame_color?**
Description: True, if the frame color is set

This method is a convenience method for "has_frame_color?(true)"
This method has been introduced in version 0.22.

has_line_style?

(1) Signature: *[const]* bool **has_line_style?** (bool real)
Description: Gets a value indicating whether the line style is set

This method has been introduced in version 0.25.

(2) Signature: *[const]* bool **has_line_style?**
Description: True, if the line style is set

This method is a convenience method for "has_line_style?(true)"
This method has been introduced in version 0.25.

has_lower_hier_level?

(1) Signature: *[const]* bool **has_lower_hier_level?** (bool real)
Description: Gets a value indicating whether a lower hierarchy level is explicitly specified

If "real" is true, the effective value is returned.

(2) Signature: *[const]* bool **has_lower_hier_level?**
Description: Gets a value indicating whether a lower hierarchy level is explicitly specified

This method is a convenience method for "has_lower_hier_level?(true)"
This method has been introduced in version 0.22.

has_source_name?

(1) Signature: *[const]* bool **has_source_name?** (bool real)
Description: Gets a value indicating whether a stream layer name is specified for this layer

If "real" is true, the effective value is returned.

(2) Signature: *[const]* bool **has_source_name?**
Description: Gets a value indicating whether a stream layer name is specified for this layer

This method is a convenience method for "has_source_name?(true)"
This method has been introduced in version 0.22.

has_upper_hier_level?

(1) Signature: *[const]* bool **has_upper_hier_level?** (bool real)
Description: Gets a value indicating whether an upper hierarchy level is explicitly specified

If "real" is true, the effective value is returned.

(2) Signature: *[const]* bool **has_upper_hier_level?**
Description: Gets a value indicating whether an upper hierarchy level is explicitly specified

This method is a convenience method for "has_upper_hier_level?(true)"
This method has been introduced in version 0.22.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

layer_index

Signature: *[const]* int **layer_index**

Description: Gets the the layer index

This is the index of the actual layer used. The source specification given by source_layer, source_datatype, source_name is evaluated and the corresponding layer is looked up in the layout object. If a source_layer_index is specified, this layer index is taken as the layer index to use.

line_style

(1) Signature: *[const]* int **line_style** (bool real)

Description: Gets the line style index

real: Set to true to return the real instead of local value

This method may deliver an invalid line style index if it is not set (see has_line_style?).

This method has been introduced in version 0.25.

Python specific notes:
This method is available as 'line_style_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* int **line_style**

Description: Gets the line style index

This method is a convenience method for "line_style(true)"

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'line_style'. This is the getter.

line_style=

Signature: void **line_style=** (int index)

Description: Sets the line style index

The line style index must be one of the valid indices. The first indices are reserved for built-in pattern, the following ones are custom pattern. Index 0 is always solid filled. For custom line styles see LayoutView#add_line_style.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'line_style'. This is the setter.

lower_hier_level

(1) Signature: *[const]* int **lower_hier_level** (bool real)

Description: Gets the lower hierarchy level shown

This is the hierarchy level at which the drawing starts. This property is only meaningful, if has_lower_hier_level is true. The hierarchy level can be relative in which case, 0 refers to the context cell's level. A mode can be specified for the hierarchy level which is 0 for absolute, 1 for minimum of specified level and set level and 2 for maximum of specified level and set level.

Python specific notes:

This method is available as 'lower_hier_level_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* int **lower_hier_level**

Description: Gets the lower hierarchy level shown

This method is a convenience method for "lower_hier_level(true)"

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'lower_hier_level'. This is the getter.

lower_hier_level=

Signature: void **lower_hier_level=** (int level)

Description: Sets the lower hierarchy level

If this method is called, the lower hierarchy level is enabled. See lower_hier_level for a description of this property.

Python specific notes:
The object exposes a writable attribute 'lower_hier_level'. This is the setter.

lower_hier_level_mode

(1) Signature: *[const]* int **lower_hier_level_mode** (bool real)

Description: Gets the mode for the lower hierarchy level.

real:	If true, the computed value is returned, otherwise the local node value

The mode value can be 0 (value is given by lower_hier_level), 1 for "minimum value" and 2 for "maximum value".

This method has been introduced in version 0.20.

(2) Signature: *[const]* int **lower_hier_level_mode**

Description: Gets the mode for the lower hierarchy level.

This method is a convenience method for "lower_hier_level_mode(true)"

This method has been introduced in version 0.22.

lower_hier_level_relative

(1) Signature: *[const]* bool **lower_hier_level_relative** (bool real)

Description: Gets a value indicating whether the lower hierarchy level is relative.

Use of this method is deprecated. Use lower_hier_level_relative? instead

See lower_hier_level for a description of this property.

This method has been introduced in version 0.19.

(2) Signature: *[const]* bool **lower_hier_level_relative**

Description: Gets a value indicating whether the upper hierarchy level is relative.

Use of this method is deprecated. Use lower_hier_level_relative? instead

This method is a convenience method for "lower_hier_level_relative(true)"

This method has been introduced in version 0.22.

lower_hier_level_relative?

(1) Signature: *[const]* bool **lower_hier_level_relative?** (bool real)

Description: Gets a value indicating whether the lower hierarchy level is relative.

See lower_hier_level for a description of this property.

This method has been introduced in version 0.19.

(2) Signature: *[const]* bool **lower_hier_level_relative?**

Description: Gets a value indicating whether the upper hierarchy level is relative.

This method is a convenience method for "lower_hier_level_relative(true)"

This method has been introduced in version 0.22.

marked=

Signature: void **marked=** (bool marked)

Description: Sets the marked state

Python specific notes:
The object exposes a writable attribute 'marked'. This is the setter.

marked?

(1) Signature: *[const]* bool **marked?** (bool real)

Description: Gets the marked state

Python specific notes:
This method is available as 'marked_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* bool **marked?**

Description: Gets the marked state

This method is a convenience method for "marked?(true)"

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'marked'. This is the getter.

name

Signature: *[const]* string **name**

Description: Gets the name

Python specific notes:
The object exposes a readable attribute 'name'. This is the getter.

name=

Signature: void **name=** (string name)

Description: Sets the name to the given string

Python specific notes:
The object exposes a writable attribute 'name'. This is the setter.

new

Signature: *[static]* new LayerProperties ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

set_lower_hier_level

(1) Signature: void **set_lower_hier_level** (int level, bool relative)

Description: Sets the lower hierarchy level and if it is relative to the context cell

If this method is called, the lower hierarchy level is enabled. See lower_hier_level for a description of this property.

This method has been introduced in version 0.19.

(2) Signature: void **set_lower_hier_level** (int level, bool relative, int mode)

Description: Sets the lower hierarchy level, whether it is relative to the context cell and the mode

If this method is called, the lower hierarchy level is enabled. See lower_hier_level for a description of this property.

This method has been introduced in version 0.20.

set_upper_hier_level

(1) Signature: void **set_upper_hier_level** (int level, bool relative)

Description: Sets the upper hierarchy level and if it is relative to the context cell

If this method is called, the upper hierarchy level is enabled. See upper_hier_level for a description of this property.

This method has been introduced in version 0.19.

(2) Signature: void **set_upper_hier_level** (int level, bool relative, int mode)

Description: Sets the upper hierarchy level, if it is relative to the context cell and the mode

If this method is called, the upper hierarchy level is enabled. See upper_hier_level for a description of this property.

This method has been introduced in version 0.20.

source

(1) Signature: *[const]* string **source** (bool real)

Description: Gets the source specification

real: Set to true to return the computed instead of local value

This method delivers the source specification as a string

Python specific notes:
This method is available as 'source_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* string **source**

Description: Gets the source specification

This method is a convenience method for "source(true)"

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'source'. This is the getter.

source=

Signature: void **source=** (string s)

Description: Loads the source specification from a string

Sets the source specification to the given string. The source specification may contain the cellview index, the source layer (given by layer/datatype or layer name), transformation, property selector etc. This method throws an exception if the specification is not valid.

Python specific notes:
The object exposes a writable attribute 'source'. This is the setter.

source_cellview

(1) Signature: *[const]* int **source_cellview** (bool real)

Description: Gets the cellview index that this layer refers to

If "real" is true, the effective value is returned.

Python specific notes:
This method is available as 'source_cellview_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* int **source_cellview**

Description: Gets the cellview index that this layer refers to

This method is a convenience method for "source_cellview(true)"

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'source_cellview'. This is the getter.

source_cellview=

Signature: void **source_cellview=** (int cellview_index)

Description: Sets the cellview index that this layer refers to

See cellview for a description of the transformations.

Python specific notes:
The object exposes a writable attribute 'source_cellview'. This is the setter.

source_datatype

(1) Signature: *[const]* int **source_datatype** (bool real)

Description: Gets the stream datatype that the shapes are taken from

If the datatype is positive, the actual layer is looked up by this stream datatype. If a name or layer index is specified, the stream datatype is not used.

If "real" is true, the effective value is returned.

Python specific notes:
This method is available as 'source_datatype_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* int **source_datatype**

Description: Gets the stream datatype that the shapes are taken from

This method is a convenience method for "source_datatype(true)"

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'source_datatype'. This is the getter.

source_datatype=

Signature: void **source_datatype=** (int datatype)

Description: Sets the stream datatype that the shapes are taken from

See datatype for a description of this property

Python specific notes:
The object exposes a writable attribute 'source_datatype'. This is the setter.

source_layer

(1) Signature: *[const]* int **source_layer** (bool real)

Description: Gets the stream layer that the shapes are taken from

If the layer is positive, the actual layer is looked up by this stream layer. If a name or layer index is specified, the stream layer is not used.

If "real" is true, the effective value is returned.

Python specific notes:
This method is available as 'source_layer_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* int **source_layer**

Description: Gets the stream layer that the shapes are taken from

This method is a convenience method for "source_layer(true)"

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'source_layer'. This is the getter.

source_layer=

Signature: void **source_layer=** (int layer)

Description: Sets the stream layer that the shapes are taken from

See source_layer for a description of this property

Python specific notes:
The object exposes a writable attribute 'source_layer'. This is the setter.

source_layer_index

(1) Signature: *[const]* int **source_layer_index** (bool real)

Description: Gets the layer index that the shapes are taken from

If the layer index is positive, the shapes drawn are taken from this layer rather than searched for by layer and datatype. This property is stronger than the layer/datatype or name specification.

A different method is layer_index which indicates the ID of the layer actually used. While "source_layer_index" is one of several ways to address the layer drawn, "layer_index" is the ID (index) of the layer matching the source specification and is >= 0 if such a layer is found.

If "real" is true, the effective value is returned.

Python specific notes:
This method is available as 'source_layer_index_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* int **source_layer_index**

Description: Gets the stream layer that the shapes are taken from

This method is a convenience method for "source_layer_index(true)"

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'source_layer_index'. This is the getter.

source_layer_index=

Signature: void **source_layer_index=** (int index)

Description: Sets the layer index specification that the shapes are taken from

See source_layer_index for a description of this property.

Python specific notes:
The object exposes a writable attribute 'source_layer_index'. This is the setter.

source_name

(1) Signature: *[const]* string **source_name** (bool real)

Description: Gets the stream name that the shapes are taken from

If the name is non-empty, the actual layer is looked up by this stream layer name. If a layer index (see layer_index) is specified, the stream datatype is not used. A name is only meaningful for OASIS files.

If "real" is true, the effective value is returned.

Python specific notes:
This method is available as 'source_name_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* string **source_name**

Description: Gets the stream name that the shapes are taken from

This method is a convenience method for "source_name(true)"

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'source_name'. This is the getter.

source_name=

Signature: void **source_name=** (string name)

Description: Sets the stream layer name that the shapes are taken from

See name for a description of this property

Python specific notes:
The object exposes a writable attribute 'source_name'. This is the setter.

trans

(1) Signature: *[const]* DCplxTrans[] **trans** (bool real)

Description: Gets the transformations that the layer is transformed with

The transformations returned by this accessor is the one used for displaying this layer. The layout is transformed with each of these transformations before it is drawn.

If "real" is true, the effective value is returned.

Python specific notes:
This method is available as 'trans_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* DCplxTrans[] **trans**

Description: Gets the transformations that the layer is transformed with

This method is a convenience method for "trans(true)"

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'trans'. This is the getter.

trans=

Signature: void **trans=** (DCplxTrans[] trans_vector)

Description: Sets the transformations that the layer is transformed with

See trans for a description of the transformations.

Python specific notes:
The object exposes a writable attribute 'trans'. This is the setter.

transparent=

Signature: void **transparent=** (bool transparent)

Description: Sets the transparency state

Python specific notes:
The object exposes a writable attribute 'transparent'. This is the setter.

transparent?

(1) Signature: *[const]* bool **transparent?** (bool real)

Description: Gets the transparency state

Python specific notes:
This method is available as 'transparent_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* bool **transparent?**

Description: Gets the transparency state

This method is a convenience method for "transparent?(true)"

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'transparent'. This is the getter.

upper_hier_level

(1) Signature: *[const]* int **upper_hier_level** (bool real)

Description: Gets the upper hierarchy level shown

This is the hierarchy level at which the drawing starts. This property is only meaningful, if has_upper_hier_level is true. The hierarchy level can be relative in which case, 0 refers to the context cell's level. A mode can be specified for the hierarchy level which is 0 for absolute, 1 for minimum of specified level and set level and 2 for maximum of specified level and set level.

Python specific notes:
This method is available as 'upper_hier_level_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* int **upper_hier_level**

Description: Gets the upper hierarchy level shown

This method is a convenience method for "upper_hier_level(true)"

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'upper_hier_level'. This is the getter.

upper_hier_level=

Signature: void **upper_hier_level=** (int level)

Description: Sets a upper hierarchy level

If this method is called, the upper hierarchy level is enabled. See upper_hier_level for a description of this property.

Python specific notes:
The object exposes a writable attribute 'upper_hier_level'. This is the setter.

upper_hier_level_mode

(1) Signature: *[const]* int **upper_hier_level_mode** (bool real)

Description: Gets the mode for the upper hierarchy level.

real:	If true, the computed value is returned, otherwise the local node value

The mode value can be 0 (value is given by upper_hier_level), 1 for "minimum value" and 2 for "maximum value".

This method has been introduced in version 0.20.

(2) Signature: *[const]* int **upper_hier_level_mode**

Description: Gets the mode for the upper hierarchy level.

This method is a convenience method for "upper_hier_level_mode(true)"

This method has been introduced in version 0.22.

upper_hier_level_relative

(1) Signature: *[const]* bool **upper_hier_level_relative** (bool real)

Description: Gets a value indicating whether if the upper hierarchy level is relative.

Use of this method is deprecated. Use upper_hier_level_relative? instead

See upper_hier_level for a description of this property.

This method has been introduced in version 0.19.

(2) Signature: *[const]* bool **upper_hier_level_relative**

Description: Gets a value indicating whether the upper hierarchy level is relative.

Use of this method is deprecated. Use upper_hier_level_relative? instead

This method is a convenience method for "upper_hier_level_relative(true)"

This method has been introduced in version 0.22.

upper_hier_level_relative?

(1) Signature: *[const]* bool **upper_hier_level_relative?** (bool real)

Description: Gets a value indicating whether if the upper hierarchy level is relative.

See upper_hier_level for a description of this property.

This method has been introduced in version 0.19.

(2) Signature: *[const]* bool **upper_hier_level_relative?**

Description: Gets a value indicating whether the upper hierarchy level is relative.

This method is a convenience method for "upper_hier_level_relative(true)"

This method has been introduced in version 0.22.

valid=

Signature: void **valid=** (bool valid)

Description: Sets the validity state

Python specific notes:
The object exposes a writable attribute 'valid'. This is the setter.

valid?

(1) Signature: *[const]* bool **valid?** (bool real)

Description: Gets the validity state

Python specific notes:
This method is available as 'valid_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* bool **valid?**

Description: Gets the validity state

This method is a convenience method for "valid?(true)"

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a readable attribute 'valid'. This is the getter.

visible=

Signature: void **visible=** (bool visible)

Description: Sets the visibility state

Python specific notes:
The object exposes a writable attribute 'visible'. This is the setter.

visible?

(1) Signature: *[const]* bool **visible?** (bool real)

Description: Gets the visibility state

Python specific notes:
This method is available as 'visible_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* bool **visible?**

Description: Gets the visibility state

This method is a convenience method for "visible?(true)"

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'visible'. This is the getter.

width

(1) Signature: *[const]* int **width** (bool real)

Description: Gets the line width

Python specific notes:
This method is available as 'width_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* int **width**

Description: Gets the line width

This method is a convenience method for "width(true)"

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'width'. This is the getter.

width=

Signature: void **width=** (int width)

Description: Sets the line width to the given width

Python specific notes:
The object exposes a writable attribute 'width'. This is the setter.

xfill=

Signature: void **xfill=** (bool xfill)

Description: Sets a value indicating whether shapes are drawn with a cross

This attribute has been introduced in version 0.25.

Python specific notes:

The object exposes a writable attribute 'xfill'. This is the setter.

xfill?

(1) Signature: *[const]* bool **xfill?** (bool real)

Description: Gets a value indicating whether shapes are drawn with a cross

This attribute has been introduced in version 0.25.

Python specific notes:
This method is available as 'xfill_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* bool **xfill?**

Description: Gets a value indicating whether shapes are drawn with a cross

This method is a convenience method for "xfill?(true)"

This attribute has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'xfill'. This is the getter.

4.196. API reference - Class LayerPropertiesNode

Notation used in Ruby API documentation

Module: lay

Description: A layer properties node structure

Class hierarchy: LayerPropertiesNode » LayerProperties

This class is derived from LayerProperties. Objects of this class are used in the hierarchy of layer views that are arranged in a tree while the LayerProperties object reflects the properties of a single node.

Public methods

[const]	bool	**!=**	(const LayerPropertie other)	Inequality
[const]	bool	**==**	(const LayerPropertiesNode other)	Equality
	void	**_assign**	(const LayerPropertie other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new LayerPropertiesNode ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	LayerPropertiesNodeRef	**add_child**		Add a child entry
	LayerPropertiesNodeRef	**add_child**	(const LayerProperties ptr child)	Add a child entry
[const]	DBox	**bbox**		Compute the bbox of this layer
	void	**clear_children**		Clears all children
	void	**expanded=**	(bool ex)	Set a value indicating whether the layer tree node is expanded.

[const]	LayerPropertiesNode	**flat**	return the "flattened" (effective) layer properties node for this node
[const]	bool	**has_children?**	Test, if there are children
[const]	unsigned int	**id**	Obtain the unique ID
[const]	bool	**is_expanded?**	Gets a value indicating whether the layer tree node is expanded.
[const]	unsigned int	**list_index**	Gets the index of the layer properties list that the node lives in
	LayoutView ptr	**view**	Gets the view this node lives in

Detailed description

!=

Signature: *[const]* bool **!=** (const LayerPropertiesNode other)

Description: Inequality

other: The other object to compare against

==

Signature: *[const]* bool **==** (const LayerPropertiesNode other)

Description: Equality

other: The other object to compare against

_assign

Signature: void **_assign** (const LayerPropertiesNode other)

Description: Assigns another object to self

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_dup

Signature: *[const]* new LayerPropertiesNode ptr **_dup**

Description: Creates a copy of self

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

add_child

(1) Signature: LayerPropertiesNodeRef **add_child**

Description: Add a child entry

Returns: A reference to the node created

This method allows building a layer properties tree by adding children to node objects. It returns a reference to the node object created which is a freshly initialized one.

The parameterless version of this method was introduced in version 0.25.

(2) Signature: LayerPropertiesNodeRef **add_child** (const LayerProperties ptr child)

Description: Add a child entry

Returns: A reference to the node created

This method allows building a layer properties tree by adding children to node objects. It returns a reference to the node object created.

This method was introduced in version 0.22.

bbox

Signature: *[const]* DBox **bbox**

Description: Compute the bbox of this layer

Returns: A bbox in micron units

This takes the layout and path definition (supported by the given default layout or path, if no specific is given). The node must have been attached to a view to make this operation possible.

clear_children

Signature: void **clear_children**

Description: Clears all children

This method was introduced in version 0.22.

expanded=

Signature: void **expanded=** (bool ex)

Description: Set a value indicating whether the layer tree node is expanded.

Setting this value to 'true' will expand (open) the tree node. Setting it to 'false' will collapse the node.

This predicate has been introduced in version 0.28.6.

Python specific notes:
The object exposes a writable attribute 'expanded'. This is the setter.

flat

Signature: *[const]* LayerPropertiesNode **flat**

Description: return the "flattened" (effective) layer properties node for this node

This method returns a LayerPropertiesNode object that is not embedded into a hierarchy. This object represents the effective layer properties for the given node. In particular, all 'local' properties are identical to the 'real' properties. Such an object can be used as a basis for manipulations.

Unlike the name suggests, this node will still contain a hierarchy of nodes below if the original node did so.

has_children?

Signature: *[const]* bool **has_children?**

Description: Test, if there are children

id

Signature: *[const]* unsigned int **id**

Description: Obtain the unique ID

Each layer properties node object has a unique ID that is created when a new LayerPropertiesNode object is instantiated. The ID is copied when the object is copied. The ID can be used to identify the object irregardless of its content.

is_expanded?

Signature: *[const]* bool **is_expanded?**

Description: Gets a value indicating whether the layer tree node is expanded.

This predicate has been introduced in version 0.28.6.

Python specific notes:
The object exposes a readable attribute 'expanded'. This is the getter.

list_index

Signature: *[const]* unsigned int **list_index**

Description: Gets the index of the layer properties list that the node lives in

view

Signature: LayoutView ptr **view**

Description: Gets the view this node lives in

This reference can be nil if the node is a orphan node that lives outside a view.

4.197. API reference - Class LayerPropertiesNodeRef

Notation used in Ruby API documentation

Module: lay

Description: A class representing a reference to a layer properties node

Class hierarchy: LayerPropertiesNodeRef » LayerPropertiesNode » LayerProperties

This object is returned by the layer properties iterator's current method (LayerPropertiesIterator#current). A reference behaves like a layer properties node, but changes in the node are reflected in the view it is attached to.

A typical use case for references is this:

```
# Hides a layers of a view
view = RBA::LayoutView::current
view.each_layer do |lref|
  # lref is a LayerPropertiesNodeRef object
  lref.visible = false
end
```

This class has been introduced in version 0.25.

Public methods

	void	**_assign**	(const LayerProperties other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new LayerPropertiesNodeRef ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const LayerProperties other)	Assigns the contents of the 'other' object to self.
	void	**assign**	(const LayerPropertiesNode other)	Assigns the contents of the 'other' object to self.
	void	**delete**		Erases the current node and all child nodes

[const]	LayerPropertiesNode	**dup**	Creates a LayerPropertiesNode object as a copy of the content of this node.
[const]	bool	**is_valid?**	Returns true, if the reference points to a valid layer properties node

Detailed description

_assign

Signature: void **_assign** (const LayerPropertiesNodeRef other)

Description: Assigns another object to self

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_dup

Signature: *[const]* new LayerPropertiesNodeRef ptr **_dup**

Description: Creates a copy of self

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it

is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

(1) Signature: void **assign** (const LayerPropertiesNode other)

Description: Assigns the contents of the 'other' object to self.

This version accepts a LayerPropertiesNode object and allows modification of the layer node's hierarchy. Assignment will reconfigure the layer node in the view.

(2) Signature: void **assign** (const LayerProperties other)

Description: Assigns the contents of the 'other' object to self.

This version accepts a LayerProperties object. Assignment will change the properties of the layer in the view.

delete

Signature: void **delete**

Description: Erases the current node and all child nodes

After erasing the node, the reference will become invalid.

dup

Signature: *[const]* LayerPropertiesNode **dup**

Description: Creates a LayerPropertiesNode object as a copy of the content of this node.

This method is mainly provided for backward compatibility with 0.24 and before.

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

is_valid?

Signature: *[const]* bool **is_valid?**

Description: Returns true, if the reference points to a valid layer properties node

Invalid references behave like ordinary LayerPropertiesNode objects but without the ability to update the view upon changes of attributes.

4.198. API reference - Class LayerPropertiesIterator

Notation used in Ruby API documentation

Module: lay

Description: Layer properties iterator

This iterator provides a flat view for the layers in the layer tree if used with the next method. In this mode it will descend into the hierarchy and deliver node by node as a linear (flat) sequence.

The iterator can also be used to navigate through the node hierarchy using next_sibling, down_first_child, parent etc.

The iterator also plays an important role for manipulating the layer properties tree, i.e. by specifying insertion points in the tree for the LayoutView class.

Public constructors

new LayerPropertiesIterator ptr	**new**	Creates a new object of this class

Public methods

[const]	bool	**!=**	(const LayerPropertie other)	Inequality
[const]	bool	**<**	(const LayerPropertiesIterator other)	Comparison
[const]	bool	**==**	(const LayerPropertie other)	Equality
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const LayerPropertiesIterator other)	Assigns another object to self
[const]	bool	**at_end?**		At-the-end property
[const]	bool	**at_top?**		At-the-top property

[const]	unsigned long	**child_index**		Returns the index of the child within the parent
[const]	LayerPropertiesNodeRef	**current**		Returns a reference to the layer properties node that the iterator points to
	LayerPropertiesIterator	**down_first_child**		Move to the first child
	LayerPropertiesIterator	**down_last_child**		Move to the last child
[const]	new LayerPropertiesIterator ptr	**dup**		Creates a copy of self
[const]	LayerPropertiesIterator	**first_child**		Returns the iterator pointing to the first child
[const]	bool	**is_null?**		"is null" predicate
[const]	LayerPropertiesIterator	**last_child**		Returns the iterator pointing behind the last child
	LayerPropertiesIterator	**next**		Increment operator
	LayerPropertiesIterator	**next_sibling**	(long n)	Move to the next sibling by a given distance
[const]	unsigned long	**num_siblings**		Return the number of siblings
[const]	LayerPropertiesIterator	**parent**		Returns the iterator pointing to the parent node
	LayerPropertiesIterator	**to_sibling**	(unsigned long n)	Move to the sibling with the given index
	LayerPropertiesIterator	**up**		Move up

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

!=

Signature: *[const]* bool **!=** (const LayerPropertiesIterator other)

Description: Inequality

other: The other object to compare against

<

Signature: *[const]* bool **<** (const LayerPropertiesIterator other)

Description: Comparison

other: The other object to compare against

Returns: true, if self points to an object that comes before other

==

Signature: *[const]* bool **==** (const LayerPropertiesIterator other)

Description: Equality

other: The other object to compare against

Returns true, if self and other point to the same layer properties node. Caution: this does not imply that both layer properties nodes sit in the same tab. Just their position in the tree is compared.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the

reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const LayerPropertiesIterator other)

Description: Assigns another object to self

at_end?

Signature: *[const]* bool **at_end?**

Description: At-the-end property

This predicate is true if the iterator is at the end of either all elements or at the end of the child list (if down_last_child or down_first_child is used to iterate).

at_top?

Signature: *[const]* bool **at_top?**

Description: At-the-top property

This predicate is true if there is no parent node above the node addressed by self.

child_index

Signature: *[const]* unsigned long **child_index**

Description: Returns the index of the child within the parent

This method returns the index of that the properties node the iterator points to in the list of children of its parent. If the element does not have a parent, the index of the element in the global list is returned.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

current

Signature: *[const]* LayerPropertiesNodeRef **current**

Description: Returns a reference to the layer properties node that the iterator points to

Starting with version 0.25, the returned object can be manipulated and the changes will be reflected in the view immediately.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

down_first_child

Signature: LayerPropertiesIterator **down_first_child**

Description: Move to the first child

This method moves to the first child of the current element. If there is no child, at_end? will be true. Even then, the iterator is sitting at the the child level and up can be used to move back.

down_last_child

Signature: LayerPropertiesIterator **down_last_child**

Description: Move to the last child

This method moves behind the last child of the current element. at_end? will be true then. Even then, the iterator points to the child level and up can be used to move back.

Despite the name, the iterator does not address the last child, but the position after that child. To actually get the iterator for the last child, use down_last_child and next_sibling(-1).

dup

Signature: *[const]* new LayerPropertiesIterator ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

first_child

Signature: *[const]* LayerPropertiesIterator **first_child**

Description: Returns the iterator pointing to the first child

If there is no children, the iterator will be a valid insert point but not point to any valid element. It will report at_end? = true.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_null?

Signature: *[const]* bool **is_null?**

Description: "is null" predicate

This predicate is true if the iterator is "null". Such an iterator can be created with the default constructor or by moving a top-level iterator up.

last_child

Signature: *[const]* LayerPropertiesIterator **last_child**

Description: Returns the iterator pointing behind the last child

The iterator will be a valid insert point but not point to any valid element. It will report at_end? = true.

Despite the name, the iterator does not address the last child, but the position after that child. To actually get the iterator for the last child, use last_child and call next_sibling(-1) on that iterator.

new

Signature: *[static]* new LayerPropertiesIterator ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

next

Signature: LayerPropertiesIterator **next**

Description: Increment operator

The iterator will be incremented to point to the next layer entry. It will descend into the hierarchy to address child nodes if there are any.

next_sibling

Signature: LayerPropertiesIterator **next_sibling** (long n)

Description: Move to the next sibling by a given distance

The iterator is moved to the nth next sibling of the current element. Use negative distances to move backward.

num_siblings

Signature: *[const]* unsigned long **num_siblings**

Description: Return the number of siblings

The count includes the current element. More precisely, this property delivers the number of children of the current node's parent.

parent

Signature: *[const]* LayerPropertiesIterator **parent**

Description: Returns the iterator pointing to the parent node

This method will return an iterator pointing to the parent element. If there is no parent, the returned iterator will be a null iterator.

to_sibling

Signature: LayerPropertiesIterator **to_sibling** (unsigned long n)

Description: Move to the sibling with the given index

The iterator is moved to the nth sibling by selecting the nth child in the current node's parent.

up

Signature: LayerPropertiesIterator **up**

Description: Move up

The iterator is moved to point to the current element's parent. If the current element does not have a parent, the iterator will become a null iterator.

4.199. API reference - Class LayoutView::SelectionMode

Notation used in Ruby API documentation

Module: lay

Description: Specifies how selected objects interact with already selected ones.

This class is equivalent to the class LayoutView::SelectionMode

This enum was introduced in version 0.27.

Public constructors

new LayoutView::SelectionMode ptr	**new**	(int i)	Creates an enum from an integer value
new LayoutView::SelectionMode ptr	**new**	(string s)	Creates an enum from a string value

Public methods

[const]	bool	**!=**	(const LayoutView::SelectionMc other)	Compares two enums for inequality
[const]	bool	**!=**	(int other)	Compares an enum with an integer for inequality
[const]	bool	**<**	(const LayoutView::SelectionMc other)	Returns true if the first enum is less (in the enum symbol order) than the second
[const]	bool	**<**	(int other)	Returns true if the enum is less (in the enum symbol order) than the integer value
[const]	bool	**==**	(const LayoutView::SelectionMc other)	Compares two enums
[const]	bool	**==**	(int other)	Compares an enum with an integer value
[const]	int	**hash**		Gets the hash value from the enum
[const]	string	**inspect**		Converts an enum to a visual string
[const]	int	**to_i**		Gets the integer value from the enum
[const]	string	**to_s**		Gets the symbolic string from an enum

Public static methods and constants

[static,const]	LayoutView::SelectionMode	**Add**	Adds to any existing selection
[static,const]	LayoutView::SelectionMode	**Invert**	Adds to any existing selection, if it's not there yet or removes it from the selection if it's already selected
[static,const]	LayoutView::SelectionMode	**Replace**	Replaces the existing selection

[static,const]	LayoutView::SelectionMode	**Reset**	Removes from any existing selection

Detailed description

!=	**(1) Signature**: *[const]* bool **!=** (const LayoutView::SelectionMode other) **Description**: Compares two enums for inequality **(2) Signature**: *[const]* bool **!=** (int other) **Description**: Compares an enum with an integer for inequality
<	**(1) Signature**: *[const]* bool **<** (const LayoutView::SelectionMode other) **Description**: Returns true if the first enum is less (in the enum symbol order) than the second **(2) Signature**: *[const]* bool **<** (int other) **Description**: Returns true if the enum is less (in the enum symbol order) than the integer value
==	**(1) Signature**: *[const]* bool **==** (const LayoutView::SelectionMode other) **Description**: Compares two enums **(2) Signature**: *[const]* bool **==** (int other) **Description**: Compares an enum with an integer value
Add	**Signature**: *[static,const]* LayoutView::SelectionMode **Add** **Description**: Adds to any existing selection **Python specific notes:** The object exposes a readable attribute 'Add'. This is the getter.
Invert	**Signature**: *[static,const]* LayoutView::SelectionMode **Invert** **Description**: Adds to any existing selection, if it's not there yet or removes it from the selection if it's already selected **Python specific notes:** The object exposes a readable attribute 'Invert'. This is the getter.
Replace	**Signature**: *[static,const]* LayoutView::SelectionMode **Replace** **Description**: Replaces the existing selection **Python specific notes:** The object exposes a readable attribute 'Replace'. This is the getter.
Reset	**Signature**: *[static,const]* LayoutView::SelectionMode **Reset** **Description**: Removes from any existing selection **Python specific notes:** The object exposes a readable attribute 'Reset'. This is the getter.
hash	**Signature**: *[const]* int **hash** **Description**: Gets the hash value from the enum

Python specific notes:
This method is also available as 'hash(object)'.

inspect

Signature: *[const]* string **inspect**

Description: Converts an enum to a visual string

Python specific notes:
This method is also available as 'repr(object)'.

new

(1) Signature: *[static]* new LayoutView::SelectionMode ptr **new** (int i)

Description: Creates an enum from an integer value

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new LayoutView::SelectionMode ptr **new** (string s)

Description: Creates an enum from a string value

Python specific notes:
This method is the default initializer of the object.

to_i

Signature: *[const]* int **to_i**

Description: Gets the integer value from the enum

Python specific notes:
This method is also available as 'int(object)'.

to_s

Signature: *[const]* string **to_s**

Description: Gets the symbolic string from an enum

Python specific notes:
This method is also available as 'str(object)'.

4.200. API reference - Class CellView

Notation used in Ruby API documentation

Module: lay

Description: A class describing what is shown inside a layout view

The cell view points to a specific cell within a certain layout and a hierarchical context. For that, first of all a layout pointer is provided. The cell itself is addressed by an cell_index or a cell object reference. The layout pointer can be nil, indicating that the cell view is invalid.

The cell is not only identified by its index or object but also by the path leading to that cell. This path indicates how to find the cell in the hierarchical context of its parent cells.

The path is in fact composed of two parts: first in an unspecific fashion, just describing which parent cells are used. The target of this path is called the "context cell". It is accessible by the ctx_cell_index or ctx_cell methods. In the viewer, the unspecific part of the path is the location of the cell in the cell tree.

Additionally the path's second part may further identify a specific instance of a certain subcell in the context cell. This is done through a set of InstElement objects. The target of this specific path is the actual cell addressed by the cellview. This target cell is accessible by the cell_index or cell methods. In the viewer, the target cell is shown in the context of the context cell. The hierarchy levels are counted from the context cell, which is on level 0. If the context path is empty, the context cell is identical with the target cell.

Starting with version 0.25, the cellview can be modified directly. This will have an immediate effect on the display. For example, the following code will select a different cell:

```
cv = RBA::CellView::active
cv.cell_name = "TOP2"
```

See The Application API for more details about the cellview objects.

Public constructors

new CellView ptr	**new**	Creates a new object of this class

Public methods

[const]	bool	**==**	(const CellView other)	Equality: indicates whether the cellviews refer to the same one
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**ascend**		Ascends upwards in the hierarchy.

	void	**assign**	(const CellView other)	Assigns another object to self
[const]	Cell ptr	**cell**		Gets the reference to the target cell currently addressed
	void	**cell=**	(Cell ptr cell)	Sets the cell by reference to a Cell object
[const]	unsigned int	**cell_index**		Gets the target cell's index
	void	**cell_index=**	(unsigned int cell_index)	Sets the path to the given cell
[const]	string	**cell_name**		Gets the name of the target cell currently addressed
	void	**cell_name=**	(string cell_name)	Sets the cell by name
	void	**close**		Closes this cell view
[const]	DCplxTrans	**context_dtrans**		Gets the accumulated transformation of the context path in micron unit space
[const]	InstElement[]	**context_path**		Gets the cell's context path
	void	**context_path=**	(InstElement[] path)	Sets the context path explicitly
[const]	ICplxTrans	**context_trans**		Gets the accumulated transformation of the context path
[const]	Cell ptr	**ctx_cell**		Gets the reference to the context cell currently addressed
[const]	unsigned int	**ctx_cell_index**		Gets the context cell's index
	void	**descend**	(InstElement[] path)	Descends further into the hierarchy.
[const]	new CellView ptr	**dup**		Creates a copy of self
[const]	string	**filename**		Gets filename associated with the layout behind the cellview
	void	**hide_cell**	(const Cell ptr cell)	Hides the given cell
[const]	int	**index**		Gets the index of this cellview in the layout view
	bool	**is_cell_hidden?**	(const Cell ptr cell)	Returns true, if the given cell is hidden
[const]	bool	**is_dirty?**		Gets a flag indicating whether the layout needs saving
[const]	bool	**is_valid?**		Returns true, if the cellview is valid

[const]	Layout ptr	**layout**		Gets the reference to the layout object addressed by this view
[const]	string	**name**		Gets the unique name associated with the layout behind the cellview
	void	**name=**	(string name)	sets the unique name associated with the layout behind the cellview
[signal]	void	**on_technology_changed**		An event indicating that the technology has changed
[const]	unsigned int[]	**path**		Gets the cell's unspecific part of the path leading to the context cell
	void	**path=**	(unsigned int[] path)	Sets the unspecific part of the path explicitly
	void	**reset_cell**		Resets the cell
	void	**set_cell**	(unsigned int cell_index)	Sets the path to the given cell
	void	**set_cell_name**	(string cell_name)	Sets the cell by name
	void	**set_context_path**	(InstElement[] path)	Sets the context path explicitly
	void	**set_path**	(unsigned int[] path)	Sets the unspecific part of the path explicitly
	void	**show_all_cells**		Makes all cells shown (cancel effects of hide_cell) for the specified cell view
	void	**show_cell**	(const Cell ptr cell)	Shows the given cell (cancels the effect of hide_cell)
[const]	string	**technology**		Returns the technology name for the layout behind the given cell view
[const]	void	**technology=**	(string tech_name)	Sets the technology for the layout behind the given cell view
	LayoutView ptr	**view**		Gets the view the cellview resides in

Public static methods and constants

CellView	**active**	Gets the active CellView

Deprecated methods (protected, public, static, non-static and constructors)

void	**create**	Use of this method is deprecated. Use _create instead
void	**destroy**	Use of this method is deprecated. Use _destroy instead

[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

==

Signature: *[const]* bool **==** (const CellView other)

Description: Equality: indicates whether the cellviews refer to the same one

In version 0.25, the definition of the equality operator has been changed to reflect identity of the cellview. Before that version, identity of the cell shown was implied.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the

reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

active

Signature: *[static]* CellView **active**

Description: Gets the active CellView

The active CellView is the one that is selected in the current layout view. This method is equivalent to

```
RBA::LayoutView::current.active_cellview
```

If no CellView is active, this method returns nil.

This method has been introduced in version 0.23.

ascend

Signature: void **ascend**

Description: Ascends upwards in the hierarchy.

Removes one element from the specific path of the cellview with the given index. Returns the element removed. This method has been added in version 0.25.

assign

Signature: void **assign** (const CellView other)

Description: Assigns another object to self

cell

Signature: *[const]* Cell ptr **cell**

Description: Gets the reference to the target cell currently addressed

Python specific notes:
The object exposes a readable attribute 'cell'. This is the getter.

cell=

Signature: void **cell=** (Cell ptr cell)

Description: Sets the cell by reference to a Cell object

Setting the cell reference to nil invalidates the cellview. This method will construct any path to this cell, not a particular one. It will clear the context path and update the context and target cell.

Python specific notes:
The object exposes a writable attribute 'cell'. This is the setter.

cell_index

Signature: *[const]* unsigned int **cell_index**

Description: Gets the target cell's index

Python specific notes:
The object exposes a readable attribute 'cell_index'. This is the getter.

cell_index=

Signature: void **cell_index=** (unsigned int cell_index)

Description: Sets the path to the given cell

This method will construct any path to this cell, not a particular one. It will clear the context path and update the context and target cell. Note that the cell is specified by its index.

Python specific notes:
The object exposes a writable attribute 'cell_index'. This is the setter.

cell_name

Signature: *[const]* string **cell_name**

Description: Gets the name of the target cell currently addressed

Python specific notes:
The object exposes a readable attribute 'cell_name'. This is the getter.

cell_name=

Signature: void **cell_name=** (string cell_name)

Description: Sets the cell by name

If the name is not a valid one, the cellview will become invalid. This method will construct any path to this cell, not a particular one. It will clear the context path and update the context and target cell.

Python specific notes:
The object exposes a writable attribute 'cell_name'. This is the setter.

close

Signature: void **close**

Description: Closes this cell view

This method will close the cellview - remove it from the layout view. After this method was called, the cellview will become invalid (see is_valid?).

This method was introduced in version 0.25.

context_dtrans

Signature: *[const]* DCplxTrans **context_dtrans**

Description: Gets the accumulated transformation of the context path in micron unit space

This is the transformation applied to the target cell before it is shown in the context cell Technically this is the product of all transformations over the context path. See context_trans for a version delivering an integer-unit space transformation.

This method has been introduced in version 0.27.3.

context_path

Signature: *[const]* InstElement[] **context_path**

Description: Gets the cell's context path

The context path leads from the context cell to the target cell in a specific fashion, i.e. describing each instance in detail, not just by cell indexes. If the context and target cell are identical, the context path is empty.

Python specific notes:
The object exposes a readable attribute 'context_path'. This is the getter.

context_path=

Signature: void **context_path=** (InstElement[] path)

Description: Sets the context path explicitly

This method assumes that the unspecific part of the path is established already and that the context path starts from the context cell.

Python specific notes:
The object exposes a writable attribute 'context_path'. This is the setter.

context_trans

Signature: *[const]* ICplxTrans **context_trans**

Description: Gets the accumulated transformation of the context path

This is the transformation applied to the target cell before it is shown in the context cell Technically this is the product of all transformations over the context path. See context_dtrans for a version delivering a micron-unit space transformation.

	This method has been introduced in version 0.27.3.
create	**Signature**: void **create** **Description**: Ensures the C++ object is created Use of this method is deprecated. Use _create instead Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
ctx_cell	**Signature**: *[const]* Cell ptr **ctx_cell** **Description**: Gets the reference to the context cell currently addressed
ctx_cell_index	**Signature**: *[const]* unsigned int **ctx_cell_index** **Description**: Gets the context cell's index
descend	**Signature**: void **descend** (InstElement[] path) **Description**: Descends further into the hierarchy. Adds the given path (given as an array of InstElement objects) to the specific path of the cellview with the given index. In effect, the cell addressed by the terminal of the new path components can be shown in the context of the upper cells, if the minimum hierarchy level is set to a negative value. The path is assumed to originate from the current cell and contain specific instances sorted from top to bottom. This method has been added in version 0.25.
destroy	**Signature**: void **destroy** **Description**: Explicitly destroys the object Use of this method is deprecated. Use _destroy instead Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
destroyed?	**Signature**: *[const]* bool **destroyed?** **Description**: Returns a value indicating whether the object was already destroyed Use of this method is deprecated. Use _destroyed? instead This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
dup	**Signature**: *[const]* new CellView ptr **dup** **Description**: Creates a copy of self **Python specific notes:** This method also implements '__copy__' and '__deepcopy__'.
filename	**Signature**: *[const]* string **filename** **Description**: Gets filename associated with the layout behind the cellview
hide_cell	**Signature**: void **hide_cell** (const Cell ptr cell) **Description**: Hides the given cell

This method has been added in version 0.25.

index

Signature: *[const]* int **index**

Description: Gets the index of this cellview in the layout view

The index will be negative if the cellview is not a valid one. This method has been added in version 0.25.

is_cell_hidden?

Signature: bool **is_cell_hidden?** (const Cell ptr cell)

Description: Returns true, if the given cell is hidden

This method has been added in version 0.25.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_dirty?

Signature: *[const]* bool **is_dirty?**

Description: Gets a flag indicating whether the layout needs saving

A layout is 'dirty' if it is modified and needs saving. This method returns true in this case.

This method has been introduced in version 0.24.10.

is_valid?

Signature: *[const]* bool **is_valid?**

Description: Returns true, if the cellview is valid

A cellview may become invalid if the corresponding tab is closed for example.

layout

Signature: *[const]* Layout ptr **layout**

Description: Gets the reference to the layout object addressed by this view

name

Signature: *[const]* string **name**

Description: Gets the unique name associated with the layout behind the cellview

Python specific notes:
The object exposes a readable attribute 'name'. This is the getter.

name=

Signature: void **name=** (string name)

Description: sets the unique name associated with the layout behind the cellview

this method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'name'. This is the setter.

new

Signature: *[static]* new CellView ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

on_technology_changed

Signature: *[signal]* void **on_technology_changed**

Description: An event indicating that the technology has changed

This event is triggered when the CellView is attached to a different technology.

This event has been introduced in version 0.27.

Python specific notes:
The object exposes a readable attribute 'on_technology_changed'. This is the getter.
The object exposes a writable attribute 'on_technology_changed'. This is the setter.

path

Signature: *[const]* unsigned int[] **path**

Description: Gets the cell's unspecific part of the path leading to the context cell

Python specific notes:
The object exposes a readable attribute 'path'. This is the getter.

path=

Signature: void **path=** (unsigned int[] path)

Description: Sets the unspecific part of the path explicitly

Setting the unspecific part of the path will clear the context path component and update the context and target cell.

Python specific notes:
The object exposes a writable attribute 'path'. This is the setter.

reset_cell

Signature: void **reset_cell**

Description: Resets the cell

The cellview will become invalid. The layout object will still be attached to the cellview, but no cell will be selected.

set_cell

Signature: void **set_cell** (unsigned int cell_index)

Description: Sets the path to the given cell

This method will construct any path to this cell, not a particular one. It will clear the context path and update the context and target cell. Note that the cell is specified by its index.

Python specific notes:
The object exposes a writable attribute 'cell_index'. This is the setter.

set_cell_name

Signature: void **set_cell_name** (string cell_name)

Description: Sets the cell by name

If the name is not a valid one, the cellview will become invalid. This method will construct any path to this cell, not a particular one. It will clear the context path and update the context and target cell.

Python specific notes:
The object exposes a writable attribute 'cell_name'. This is the setter.

set_context_path

Signature: void **set_context_path** (InstElement[] path)

Description: Sets the context path explicitly

This method assumes that the unspecific part of the path is established already and that the context path starts from the context cell.

Python specific notes:
The object exposes a writable attribute 'context_path'. This is the setter.

set_path

Signature: void **set_path** (unsigned int[] path)

Description: Sets the unspecific part of the path explicitly

Setting the unspecific part of the path will clear the context path component and update the context and target cell.

Python specific notes:
The object exposes a writable attribute 'path'. This is the setter.

show_all_cells

Signature: void **show_all_cells**

Description: Makes all cells shown (cancel effects of hide_cell) for the specified cell view

This method has been added in version 0.25.

show_cell

Signature: void **show_cell** (const Cell ptr cell)

Description: Shows the given cell (cancels the effect of hide_cell)

This method has been added in version 0.25.

technology

Signature: *[const]* string **technology**

Description: Returns the technology name for the layout behind the given cell view

This method has been added in version 0.23.

Python specific notes:
The object exposes a readable attribute 'technology'. This is the getter.

technology=

Signature: *[const]* void **technology=** (string tech_name)

Description: Sets the technology for the layout behind the given cell view

According to the specification of the technology, new layer properties may be loaded or the net tracer may be reconfigured. If the layout is shown in multiple views, the technology is updated for all views. This method has been added in version 0.22.

Python specific notes:
The object exposes a writable attribute 'technology'. This is the setter.

view

Signature: LayoutView ptr **view**

Description: Gets the view the cellview resides in

This reference will be nil if the cellview is not a valid one. This method has been added in version 0.25.

4.201. API reference - Class Marker

Notation used in Ruby API documentation

Module: lay

Description: The floating-point coordinate marker object

The marker is a visual object that "marks" (highlights) a certain area of the layout, given by a database object. This object accepts database objects with floating-point coordinates in micron values.

Public constructors

new Marker ptr	**new**	(LayoutView ptr view)		Creates a marker

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	unsigned int	**color**		Gets the color of the marker
	void	**color=**	(unsigned int color)	Sets the color of the marker
	void	**dismissable=**	(bool flag)	Sets a value indicating whether the marker can be hidden
[const]	bool	**dismissable?**		Gets a value indicating whether the marker can be hidden
[const]	int	**dither_pattern**		Gets the stipple pattern index
	void	**dither_pattern=**	(int index)	Sets the stipple pattern index
[const]	unsigned int	**frame_color**		Gets the frame color of the marker
	void	**frame_color=**	(unsigned int color)	Sets the frame color of the marker
[const]	int	**halo**		Gets the halo flag
	void	**halo=**	(int halo)	Sets the halo flag
[const]	bool	**has_color?**		Returns a value indicating whether the marker has a specific color

[const]	bool	**has_frame_color?**		Returns a value indicating whether the marker has a specific frame color
[const]	int	**line_style**		Get the line style
	void	**line_style=**	(int index)	Sets the line style
[const]	int	**line_width**		Gets the line width of the marker
	void	**line_width=**	(int width)	Sets the line width of the marker
	void	**reset_color**		Resets the color of the marker
	void	**reset_frame_color**		Resets the frame color of the marker
	void	**set**	(const DBox box)	Sets the box the marker is to display
	void	**set**	(const DText text)	Sets the text the marker is to display
	void	**set**	(const DEdge edge)	Sets the edge the marker is to display
	void	**set**	(const DPath path)	Sets the path the marker is to display
	void	**set**	(const DPolygon polygon)	Sets the polygon the marker is to display
	void	**set_box**	(const DBox box)	Sets the box the marker is to display
	void	**set_edge**	(const DEdge edge)	Sets the edge the marker is to display
	void	**set_path**	(const DPath path)	Sets the path the marker is to display
	void	**set_polygon**	(const DPolygon polygon)	Sets the polygon the marker is to display
	void	**set_text**	(const DText text)	Sets the text the marker is to display
[const]	int	**vertex_size**		Gets the vertex size of the marker
	void	**vertex_size=**	(int size)	Sets the vertex size of the marker

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

color

Signature: *[const]* unsigned int **color**

Description: Gets the color of the marker

This value is valid only if has_color? is true.

Python specific notes:
The object exposes a readable attribute 'color'. This is the getter.

color=

Signature: void **color=** (unsigned int color)

Description: Sets the color of the marker

The color is a 32bit unsigned integer encoding the RGB values in the lower 3 bytes (blue in the lowest significant byte). The color can be reset with reset_color, in which case, the default foreground color is used.

Python specific notes:
The object exposes a writable attribute 'color'. This is the setter.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dismissable=

Signature: void **dismissable=** (bool flag)

Description: Sets a value indicating whether the marker can be hidden

Dismissable markers can be hidden setting "View/Show Markers" to "off". The default setting is "false" meaning the marker can't be hidden.

This attribute has been introduced in version 0.25.4.

Python specific notes:
The object exposes a writable attribute 'dismissable'. This is the setter.

dismissable?

Signature: *[const]* bool **dismissable?**

Description: Gets a value indicating whether the marker can be hidden

See dismissable= for a description of this predicate.

Python specific notes:
The object exposes a readable attribute 'dismissable'. This is the getter.

dither_pattern

Signature: *[const]* int **dither_pattern**

Description: Gets the stipple pattern index

See dither_pattern= for a description of the stipple pattern index.

Python specific notes:

The object exposes a readable attribute 'dither_pattern'. This is the getter.

dither_pattern=

Signature: void **dither_pattern=** (int index)

Description: Sets the stipple pattern index

A value of -1 or less than zero indicates that the marker is not filled. Otherwise, the value indicates which pattern to use for filling the marker.

Python specific notes:
The object exposes a writable attribute 'dither_pattern'. This is the setter.

frame_color

Signature: *[const]* unsigned int **frame_color**

Description: Gets the frame color of the marker

This value is valid only if has_frame_color? is true.The set method has been added in version 0.20.

Python specific notes:
The object exposes a readable attribute 'frame_color'. This is the getter.

frame_color=

Signature: void **frame_color=** (unsigned int color)

Description: Sets the frame color of the marker

The color is a 32bit unsigned integer encoding the RGB values in the lower 3 bytes (blue in the lowest significant byte). The color can be reset with reset_frame_color, in which case the fill color is used. The set method has been added in version 0.20.

Python specific notes:
The object exposes a writable attribute 'frame_color'. This is the setter.

halo

Signature: *[const]* int **halo**

Description: Gets the halo flag

See halo= for a description of the halo flag.

Python specific notes:
The object exposes a readable attribute 'halo'. This is the getter.

halo=

Signature: void **halo=** (int halo)

Description: Sets the halo flag

The halo flag is either -1 (for taking the default), 0 to disable the halo or 1 to enable it. If the halo is enabled, a pixel border with the background color is drawn around the marker, the vertices and texts.

Python specific notes:
The object exposes a writable attribute 'halo'. This is the setter.

has_color?

Signature: *[const]* bool **has_color?**

Description: Returns a value indicating whether the marker has a specific color

has_frame_color?

Signature: *[const]* bool **has_frame_color?**

Description: Returns a value indicating whether the marker has a specific frame color

The set method has been added in version 0.20.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

line_style

Signature: *[const]* int **line_style**

Description: Get the line style

See line_style= for a description of the line style index. This method has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'line_style'. This is the getter.

line_style=

Signature: void **line_style=** (int index)

Description: Sets the line style

The line style is given by an index. 0 is solid, 1 is dashed and so forth.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'line_style'. This is the setter.

line_width

Signature: *[const]* int **line_width**

Description: Gets the line width of the marker

See line_width= for a description of the line width.

Python specific notes:
The object exposes a readable attribute 'line_width'. This is the getter.

line_width=

Signature: void **line_width=** (int width)

Description: Sets the line width of the marker

This is the width of the line drawn for the outline of the marker.

Python specific notes:
The object exposes a writable attribute 'line_width'. This is the setter.

new

Signature: *[static]* new Marker ptr **new** (LayoutView ptr view)

Description: Creates a marker

A marker is always associated with a view, in which it is shown. The view this marker is associated with must be passed to the constructor.

Python specific notes:
This method is the default initializer of the object.

reset_color

Signature: void **reset_color**

Description: Resets the color of the marker

See set_color for a description of the color property of the marker.

reset_frame_color

Signature: void **reset_frame_color**

Description: Resets the frame color of the marker

See set_frame_color for a description of the frame color property of the marker.The set method has been added in version 0.20.

set

(1) Signature: void **set** (const DBox box)

Description: Sets the box the marker is to display

Makes the marker show a box. The box must be given in micron units. If the box is empty, no marker is drawn. The set method has been added in version 0.20.

(2) Signature: void **set** (const DText text)

Description: Sets the text the marker is to display

Makes the marker show a text. The text must be given in micron units. The set method has been added in version 0.20.

(3) Signature: void **set** (const DEdge edge)

Description: Sets the edge the marker is to display

Makes the marker show a edge. The edge must be given in micron units. The set method has been added in version 0.20.

(4) Signature: void **set** (const DPath path)

Description: Sets the path the marker is to display

Makes the marker show a path. The path must be given in micron units. The set method has been added in version 0.20.

(5) Signature: void **set** (const DPolygon polygon)

Description: Sets the polygon the marker is to display

Makes the marker show a polygon. The polygon must be given in micron units. The set method has been added in version 0.20.

set_box

Signature: void **set_box** (const DBox box)

Description: Sets the box the marker is to display

Makes the marker show a box. The box must be given in micron units. If the box is empty, no marker is drawn. The set method has been added in version 0.20.

set_edge

Signature: void **set_edge** (const DEdge edge)

Description: Sets the edge the marker is to display

Makes the marker show a edge. The edge must be given in micron units. The set method has been added in version 0.20.

set_path

Signature: void **set_path** (const DPath path)

Description: Sets the path the marker is to display

Makes the marker show a path. The path must be given in micron units. The set method has been added in version 0.20.

set_polygon

Signature: void **set_polygon** (const DPolygon polygon)

Description: Sets the polygon the marker is to display

	Makes the marker show a polygon. The polygon must be given in micron units. The set method has been added in version 0.20.
set_text	**Signature**: void **set_text** (const DText text) **Description**: Sets the text the marker is to display Makes the marker show a text. The text must be given in micron units. The set method has been added in version 0.20.
vertex_size	**Signature**: *[const]* int **vertex_size** **Description**: Gets the vertex size of the marker See vertex_size= for a description. **Python specific notes:** The object exposes a readable attribute 'vertex_size'. This is the getter.
vertex_size=	**Signature**: void **vertex_size=** (int size) **Description**: Sets the vertex size of the marker This is the size of the rectangles drawn for the vertices object. **Python specific notes:** The object exposes a writable attribute 'vertex_size'. This is the setter.

4.202. API reference - Class AbstractMenu

Notation used in Ruby API documentation

Module: lay

Description: An abstraction for the application menus

The abstract menu is a class that stores a main menu and several popup menus in a generic form such that they can be manipulated and converted into GUI objects.

Each item can be associated with a Action, which delivers a title, enabled/disable state etc. The Action is either provided when new entries are inserted or created upon initialisation.

The abstract menu class provides methods to manipulate the menu structure (the state of the menu items, their title and shortcut key is provided and manipulated through the Action object).

Menu items and submenus are referred to by a "path". The path is a string with this interpretation:

""	is the root
"[<path>.]<name>"	is an element of the submenu given by <path>. If <path> is omitted, this refers to an element in the root
"[<path>.]end"	refers to the item past the last item of the submenu given by <path> or root
"[<path>.]begin"	refers to the first item of the submenu given by <path> or root
"[<path>.]#<n>"	refers to the nth item of the submenu given by <path> or root (n is an integer number)

Menu items can be put into groups. The path strings of each group can be obtained with the "group" method. An item is put into a group by appending ":<group-name>" to the item's name. This specification can be used several times.

Detached menus (i.e. for use in context menus) can be created as virtual top-level submenus with a name of the form "@<name>". A special detached menu is "@toolbar" which represents the tool bar of the main window. Menus are closely related to the Action class. Actions are used to represent selectable items inside menus, provide the title and other configuration settings. Actions also link the menu items with code. See the Action class description for further details.

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	Action ptr	**action**	(string path)	Gets the reference to a Action object associated with the given path
	void	**clear_menu**	(string path)	Deletes the children of the item given by the path
	void	**delete_item**	(string path)	Deletes the item given by the path

[const]	string[]	**group**	(string group)	Gets the group members
	void	**insert_item**	(string path, string name, const Action ptr action)	Inserts a new item before the one given by the path
	void	**insert_menu**	(string path, string name, string title)	Inserts a new submenu before the item given by the path
	void	**insert_menu**	(string path, string name, Action ptr action)	Inserts a new submenu before the item given by the path
	void	**insert_separator**	(string path, string name)	Inserts a new separator before the item given by the path
[const]	bool	**is_menu?**	(string path)	Returns true if the item is a menu
[const]	bool	**is_separator?**	(string path)	Returns true if the item is a separator
[const]	bool	**is_valid?**	(string path)	Returns true if the path is a valid one
[const]	string[]	**items**	(string path)	Gets the subitems for a given submenu

Public static methods and constants

	string	**pack_key_binding**	(map<string,string> path_to_keys)	Serializes a key binding definition into a single string
	string	**pack_menu_items_hidden**	(map<string,bool> path_to_visibility)	Serializes a menu item visibility definition into a single string
	map<string,string>	**unpack_key_binding**	(string s)	Deserializes a key binding definition
	map<string,bool>	**unpack_menu_items_hidden**	(string s)	Deserializes a menu item visibility definition

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

action

Signature: Action ptr **action** (string path)

Description: Gets the reference to a Action object associated with the given path

path:	The path to the item.
Returns:	A reference to a Action object associated with this path or nil if the path is not valid

clear_menu

Signature: void **clear_menu** (string path)

Description: Deletes the children of the item given by the path

path:	The path to the item whose children to delete

This method has been introduced in version 0.28.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

delete_item

Signature: void **delete_item** (string path)

Description: Deletes the item given by the path

path:	The path to the item to delete

This method will also delete all children of the given item. To clear the children only, use clear_menu.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

group

Signature: *[const]* string[] **group** (string group)

Description: Gets the group members

group:	The group name
A:	vector of all members (by path) of the group

insert_item

Signature: void **insert_item** (string path, string name, const Action ptr action)

Description: Inserts a new item before the one given by the path

path:	The path to the item before which to insert the new item
name:	The name of the item to insert
action:	The Action object to insert

The Action object passed as the third parameter references the handler which both implements the action to perform and the menu item's appearance such as title, icon and keyboard shortcut.

insert_menu

(1) Signature: void **insert_menu** (string path, string name, string title)

Description: Inserts a new submenu before the item given by the path

path:	The path to the item before which to insert the submenu
name:	The name of the submenu to insert

title: The title of the submenu to insert

The title string optionally encodes the key shortcut and icon resource in the form <text>["("<shortcut>")"]["<"<icon-resource>">"].

(2) Signature: void **insert_menu** (string path, string name, Action ptr action)

Description: Inserts a new submenu before the item given by the path

path: The path to the item before which to insert the submenu

name: The name of the submenu to insert

action: The action object of the submenu to insert

This method variant has been added in version 0.28.

insert_separator

Signature: void **insert_separator** (string path, string name)

Description: Inserts a new separator before the item given by the path

path: The path to the item before which to insert the separator

name: The name of the separator to insert

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_menu?

Signature: *[const]* bool **is_menu?** (string path)

Description: Returns true if the item is a menu

path: The path to the item

Returns: false if the path is not valid or is not a menu

is_separator?

Signature: *[const]* bool **is_separator?** (string path)

Description: Returns true if the item is a separator

path: The path to the item

Returns: false if the path is not valid or is not a separator

This method has been introduced in version 0.19.

is_valid?

Signature: *[const]* bool **is_valid?** (string path)

Description: Returns true if the path is a valid one

path: The path to check

Returns: false if the path is not a valid path to an item

items

Signature: *[const]* string[] **items** (string path)

Description: Gets the subitems for a given submenu

path: The path to the submenu

	Returns:	A vector or path strings for the child items or an empty vector if the path is not valid or the item does not have children

pack_key_binding

Signature: *[static]* string **pack_key_binding** (map<string,string> path_to_keys)

Description: Serializes a key binding definition into a single string

The serialized format is used by the 'key-bindings' config key. This method will take an array of path/key definitions (including the Action#NoKeyBound option) and convert it to a single string suitable for assigning to the config key.

This method has been introduced in version 0.26.

pack_menu_items_hidden

Signature: *[static]* string **pack_menu_items_hidden** (map<string,bool> path_to_visibility)

Description: Serializes a menu item visibility definition into a single string

The serialized format is used by the 'menu-items-hidden' config key. This method will take an array of path/visibility flag definitions and convert it to a single string suitable for assigning to the config key.

This method has been introduced in version 0.26.

unpack_key_binding

Signature: *[static]* map<string,string> **unpack_key_binding** (string s)

Description: Deserializes a key binding definition

This method is the reverse of pack_key_binding.

This method has been introduced in version 0.26.

unpack_menu_items_hidden

Signature: *[static]* map<string,bool> **unpack_menu_items_hidden** (string s)

Description: Deserializes a menu item visibility definition

This method is the reverse of pack_menu_items_hidden.

This method has been introduced in version 0.26.

4.203. API reference - Class Action

Notation used in Ruby API documentation

Module: lay

Description: The abstraction for an action (i.e. used inside menus)

Class hierarchy: Action

Actions act as a generalization of menu entries. The action provides the appearance of a menu entry such as title, key shortcut etc. and dispatches the menu events. The action can be manipulated to change to appearance of a menu entry and can be attached an observer that receives the events when the menu item is selected.

Multiple action objects can refer to the same action internally, in which case the information and event handler is copied between the incarnations. This way, a single implementation can be provided for multiple places where an action appears, for example inside the toolbar and in addition as a menu entry. Both actions will shared the same icon, text, shortcut etc.

Actions are mainly used for providing new menu items inside the AbstractMenu class. This is some sample Ruby code for that case:

```
a = RBA::Action.new
a.title = "Push Me!"
a.on_triggered do
  puts "I was pushed!"
end

app = RBA::Application.instance
mw = app.main_window

menu = mw.menu
menu.insert_separator("@toolbar.end", "name")
menu.insert_item("@toolbar.end", "my_action", a)
```

This code will register a custom action in the toolbar. When the toolbar button is pushed a message is printed. The toolbar is addressed by a path starting with the pseudo root "@toolbar".

In Version 0.23, the Action class has been merged with the ActionBase class.

Public constructors

new Action ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference
	void	**_manage**	Marks the object as managed by the script side.
	void	**_unmanage**	Marks the object as no longer owned by the script side.

	void	**checkable=**	(bool checkable)	Makes the item(s) checkable or not
	void	**checked=**	(bool checked)	Checks or unchecks the item
[const]	string	**default_shortcut**		Gets the default keyboard shortcut
	void	**default_shortcut=**	(string shortcut)	Sets the default keyboard shortcut
[const]	string	**effective_shortcut**		Gets the effective keyboard shortcut
	void	**enabled=**	(bool enabled)	Enables or disables the action
	void	**hidden=**	(bool hidden)	Sets a value that makes the item hidden always
	void	**icon=**	(string file)	Sets the icon to the given image file
	void	**icon=**	(const QIcon qicon)	Sets the icon to the given QIcon object
[const]	string	**icon_text**		Gets the icon's text
	void	**icon_text=**	(string icon_text)	Sets the icon's text
[const]	bool	**is_checkable?**		Gets a value indicating whether the item is checkable
[const]	bool	**is_checked?**		Gets a value indicating whether the item is checked
[const]	bool	**is_effective_enabled?**		Gets a value indicating whether the item is really enabled
[const]	bool	**is_effective_visible?**		Gets a value indicating whether the item is really visible
[const]	bool	**is_enabled?**		Gets a value indicating whether the item is enabled
[const]	bool	**is_hidden?**		Gets a value indicating whether the item is hidden
[const]	bool	**is_separator?**		Gets a value indicating whether the item is a separator
[const]	bool	**is_visible?**		Gets a value indicating whether the item is visible
[const]	Macro ptr	**macro**		Gets the macro associated with the action
[virtual]	void	**menu_opening**		This method is called if the menu item is a sub-menu and before the menu is opened.

[signal]	void	**on_menu_opening**		This event is called if the menu item is a sub-menu and before the menu is opened.
[signal]	void	**on_triggered**		This event is called if the menu item is selected.
	void	**separator=**	(bool separator)	Makes an item a separator or not
[const]	string	**shortcut**		Gets the keyboard shortcut
	void	**shortcut=**	(string shortcut)	Sets the keyboard shortcut
[const]	string	**title**		Gets the title
	void	**title=**	(string title)	Sets the title
[const]	string	**tool_tip**		Gets the tool tip text.
	void	**tool_tip=**	(string text)	Sets the tool tip text
	void	**trigger**		Triggers the action programmatically
[virtual]	void	**triggered**		This method is called if the menu item is selected.
	void	**visible=**	(bool visible)	Sets the item's visibility
[virtual,const]	bool	**wants_enabled**		Returns a value whether the action wants to become enabled.
[virtual,const]	bool	**wants_visible**		Returns a value whether the action wants to become visible

Public static methods and constants

[static,const]	string	**NoKeyBound**	Gets a shortcut value indicating that no shortcut shall be assigned

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

NoKeyBound

Signature: *[static,const]* string **NoKeyBound**

Description: Gets a shortcut value indicating that no shortcut shall be assigned

This method has been introduced in version 0.26.

Python specific notes:
The object exposes a readable attribute 'NoKeyBound'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

checkable=

Signature: void **checkable=** (bool checkable)

Description: Makes the item(s) checkable or not

checkable: true to make the item checkable

Python specific notes:
The object exposes a writable attribute 'checkable'. This is the setter.

checked=

Signature: void **checked=** (bool checked)

Description: Checks or unchecks the item

checked: true to make the item checked

Python specific notes:
The object exposes a writable attribute 'checked'. This is the setter.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

default_shortcut

Signature: *[const]* string **default_shortcut**

Description: Gets the default keyboard shortcut

Returns: The default keyboard shortcut as a string

This attribute has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'default_shortcut'. This is the getter.

default_shortcut=

Signature: void **default_shortcut=** (string shortcut)

Description: Sets the default keyboard shortcut

The default shortcut is used, if shortcut is empty.

This attribute has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'default_shortcut'. This is the setter.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

effective_shortcut

Signature: *[const]* string **effective_shortcut**

Description: Gets the effective keyboard shortcut

Returns: The effective keyboard shortcut as a string

The effective shortcut is the one that is taken. It's either shortcut or default_shortcut.

This attribute has been introduced in version 0.25.

enabled=

Signature: void **enabled=** (bool enabled)

Description: Enables or disables the action

enabled: true to enable the item

Python specific notes:
The object exposes a writable attribute 'enabled'. This is the setter.

hidden=

Signature: void **hidden=** (bool hidden)

Description: Sets a value that makes the item hidden always

See is_hidden? for details.

This attribute has been introduced in version 0.25

Python specific notes:
The object exposes a writable attribute 'hidden'. This is the setter.

icon=

(1) Signature: void **icon=** (string file)

Description: Sets the icon to the given image file

file: The image file to load for the icon

Passing an empty string will reset the icon.

Python specific notes:
The object exposes a writable attribute 'icon'. This is the setter.

(2) Signature: void **icon=** (const QIcon qicon)

Description: Sets the icon to the given QIcon object

qicon: The QIcon object

This variant has been added in version 0.28.

Python specific notes:
The object exposes a writable attribute 'icon'. This is the setter.

icon_text

Signature: *[const]* string **icon_text**

Description: Gets the icon's text

Python specific notes:
The object exposes a readable attribute 'icon_text'. This is the getter.

icon_text=

Signature: void **icon_text=** (string icon_text)

Description: Sets the icon's text

If an icon text is set, this will be used for the text below the icon. If no icon text is set, the normal text will be used for the icon. Passing an empty string will reset the icon's text.

Python specific notes:

	The object exposes a writable attribute 'icon_text'. This is the setter.
is_checkable?	**Signature**: *[const]* bool **is_checkable?** **Description**: Gets a value indicating whether the item is checkable **Python specific notes:** The object exposes a readable attribute 'checkable'. This is the getter.
is_checked?	**Signature**: *[const]* bool **is_checked?** **Description**: Gets a value indicating whether the item is checked **Python specific notes:** The object exposes a readable attribute 'checked'. This is the getter.
is_const_object?	**Signature**: *[const]* bool **is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.
is_effective_enabled?	**Signature**: *[const]* bool **is_effective_enabled?** **Description**: Gets a value indicating whether the item is really enabled This is the combined value from is_enabled? and dynamic value (wants_enabled). This attribute has been introduced in version 0.28.
is_effective_visible?	**Signature**: *[const]* bool **is_effective_visible?** **Description**: Gets a value indicating whether the item is really visible This is the combined visibility from is_visible? and is_hidden? and dynamic visibility (wants_visible). This attribute has been introduced in version 0.25.
is_enabled?	**Signature**: *[const]* bool **is_enabled?** **Description**: Gets a value indicating whether the item is enabled **Python specific notes:** The object exposes a readable attribute 'enabled'. This is the getter.
is_hidden?	**Signature**: *[const]* bool **is_hidden?** **Description**: Gets a value indicating whether the item is hidden If an item is hidden, it's always hidden and is_visible? does not have an effect. This attribute has been introduced in version 0.25. **Python specific notes:** The object exposes a readable attribute 'hidden'. This is the getter.
is_separator?	**Signature**: *[const]* bool **is_separator?** **Description**: Gets a value indicating whether the item is a separator This method has been introduced in version 0.25. **Python specific notes:** The object exposes a readable attribute 'separator'. This is the getter.

is_visible?

Signature: *[const]* bool **is_visible?**

Description: Gets a value indicating whether the item is visible

The visibility combines with is_hidden?. To get the true visiblity, use is_effective_visible?.

Python specific notes:
The object exposes a readable attribute 'visible'. This is the getter.

macro

Signature: *[const]* Macro ptr **macro**

Description: Gets the macro associated with the action

If the action is associated with a macro, this method returns a reference to the Macro object. Otherwise, this method returns nil.

This method has been added in version 0.25.

menu_opening

Signature: *[virtual]* void **menu_opening**

Description: This method is called if the menu item is a sub-menu and before the menu is opened.

Reimplement this method is a derived class to receive this event. You can also use the on_menu_opening event instead.

This method has been added in version 0.28.

new

Signature: *[static]* new Action ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

on_menu_opening

Signature: *[signal]* void **on_menu_opening**

Description: This event is called if the menu item is a sub-menu and before the menu is opened.

This event provides an opportunity to populate the menu before it is opened.

This event has been introduced in version 0.28.

Python specific notes:
The object exposes a readable attribute 'on_menu_opening'. This is the getter.
The object exposes a writable attribute 'on_menu_opening'. This is the setter.

on_triggered

Signature: *[signal]* void **on_triggered**

Description: This event is called if the menu item is selected.

This event has been introduced in version 0.21 and moved to the ActionBase class in 0.28.

Python specific notes:
The object exposes a readable attribute 'on_triggered'. This is the getter.
The object exposes a writable attribute 'on_triggered'. This is the setter.

separator=

Signature: void **separator=** (bool separator)

Description: Makes an item a separator or not

separator: true to make the item a separator

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'separator'. This is the setter.

shortcut

Signature: *[const]* string **shortcut**

Description: Gets the keyboard shortcut

Returns: The keyboard shortcut as a string

Python specific notes:
The object exposes a readable attribute 'shortcut'. This is the getter.

shortcut=

Signature: void **shortcut=** (string shortcut)

Description: Sets the keyboard shortcut

shortcut: The keyboard shortcut in Qt notation (i.e. "Ctrl+C")

If the shortcut string is empty, the default shortcut will be used. If the string is equal to Action#NoKeyBound, no keyboard shortcut will be assigned.

The NoKeyBound option has been added in version 0.26.

Python specific notes:
The object exposes a writable attribute 'shortcut'. This is the setter.

title

Signature: *[const]* string **title**

Description: Gets the title

Returns: The current title string

Python specific notes:
The object exposes a readable attribute 'title'. This is the getter.

title=

Signature: void **title=** (string title)

Description: Sets the title

title: The title string to set (just the title)

Python specific notes:
The object exposes a writable attribute 'title'. This is the setter.

tool_tip

Signature: *[const]* string **tool_tip**

Description: Gets the tool tip text.

This method has been added in version 0.22.

Python specific notes:
The object exposes a readable attribute 'tool_tip'. This is the getter.

tool_tip=

Signature: void **tool_tip=** (string text)

Description: Sets the tool tip text

The tool tip text is displayed in the tool tip window of the menu entry. This is in particular useful for entries in the tool bar. This method has been added in version 0.22.

Python specific notes:
The object exposes a writable attribute 'tool_tip'. This is the setter.

trigger

Signature: void **trigger**

Description: Triggers the action programmatically

triggered

Signature: *[virtual]* void **triggered**

Description: This method is called if the menu item is selected.

Reimplement this method is a derived class to receive this event. You can also use the on_triggered event instead.

visible=

Signature: void **visible=** (bool visible)

Description: Sets the item's visibility

visible: true to make the item visible

Python specific notes:
The object exposes a writable attribute 'visible'. This is the setter.

wants_enabled

Signature: *[virtual,const]* bool **wants_enabled**

Description: Returns a value whether the action wants to become enabled.

This is a dynamic query for enabled state which the system uses to dynamically show or hide menu items. This information is evaluated in addition to is_enabled? and contributes to the effective enabled status from is_effective_enabled?.

This feature has been introduced in version 0.28.

wants_visible

Signature: *[virtual,const]* bool **wants_visible**

Description: Returns a value whether the action wants to become visible

This is a dynamic query for visibility which the system uses to dynamically show or hide menu items, for example in the MRU lists. This visibility information is evaluated in addition to is_visible? and is_hidden? and contributes to the effective visibility status from is_effective_visible?.

This feature has been introduced in version 0.28.

4.204. API reference - Class PluginFactory

Notation used in Ruby API documentation

Module: lay

Description: The plugin framework's plugin factory object

Plugins are components that extend KLayout's functionality in various aspects. Scripting support exists currently for providing mouse mode handlers and general on-demand functionality connected with a menu entry.

Plugins are objects that implement the Plugin interface. Each layout view is associated with one instance of such an object. The PluginFactory is a singleton which is responsible for creating Plugin objects and providing certain configuration information such as where to put the menu items connected to this plugin and what configuration keys are used.

An implementation of PluginFactory must at least provide an implementation of create_plugin. This method must instantiate a new object of the specific plugin.

After the factory has been created, it must be registered in the system using one of the register methods. It is therefore recommended to put the call to register at the end of the "initialize" method. For the registration to work properly, the menu items must be defined before register is called.

The following features can also be implemented:

- Reserve keys in the configuration file using add_option in the constructor
- Create menu items by using add_menu_entry in the constructor
- Set the title for the mode entry that appears in the tool bar using the register argument
- Provide global functionality (independent from the layout view) using configure or menu_activated

This is a simple example for a plugin in Ruby. It switches the mouse cursor to a 'cross' cursor when it is active:

```
class PluginTestFactory < RBA::PluginFactory

  # Constructor
  def initialize
    # registers the new plugin class at position 100000 (at the end), with name
    # "my_plugin_test" and title "My plugin test"
    register(100000, "my_plugin_test", "My plugin test")
  end

  # Create a new plugin instance of the custom type
  def create_plugin(manager, dispatcher, view)
    return PluginTest.new
  end

end

# The plugin class
class PluginTest < RBA::Plugin
  def mouse_moved_event(p, buttons, prio)
    if prio
      # Set the cursor to cross if our plugin is active.
      set_cursor(RBA::Cursor::Cross)
    end
    # Returning false indicates that we don't want to consume the event.
    # This way for example the cursor position tracker still works.
    false
  end
  def mouse_click_event(p, buttons, prio)
    if prio
      puts "mouse button clicked."
      # This indicates we want to consume the event and others don't receive the mouse click
      # with prio = false.
```

```
      return true
    end
    # don't consume the event if we are not active.
    false
  end
end

# Instantiate the new plugin factory.
PluginTestFactory.new
```

This class has been introduced in version 0.22.

Public constructors

new PluginFactory ptr	new	Creates a new object of this class

Public methods

	void	_create		Ensures the C++ object is created
	void	_destroy		Explicitly destroys the object
[const]	bool	_destroyed?		Returns a value indicating whether the object was already destroyed
[const]	bool	_is_const_object?		Returns a value indicating whether the reference is a const reference
	void	_manage		Marks the object as managed by the script side.
	void	_unmanage		Marks the object as no longer owned by the script side.
	void	add_config_menu_iter	(string menu_name, string insert_pos, string title, string cname, string cvalue)	Adds a configuration menu item
	void	add_menu_entry	(string menu_name, string insert_pos)	Specifies a separator
	void	add_menu_entry	(string symbol, string menu_name, string insert_pos, string title)	Specifies a menu item
	void	add_menu_item_clone	(string symbol, string menu_name, string insert_pos, string copy_from)	Specifies a menu item as a clone of another one
	void	add_option	(string name, string default_value)	Specifies configuration variables.
	void	add_submenu	(string menu_name, string insert_pos,	Specifies a menu item or sub-menu

			string title)	
[virtual]	void	**config_finalize**		Gets called after a set of configuration events has been sent
[virtual]	bool	**configure**	(string name, string value)	Gets called for configuration events for the plugin singleton
[virtual,const	new Plugin ptr	**create_plugin**	(Manager ptr manager, Dispatcher ptr dispatcher, LayoutView ptr view)	Creates the plugin
	void	**has_tool_entry=**	(bool f)	Enables or disables the tool bar entry
[virtual]	void	**initialized**	(Dispatcher ptr dispatcher)	Gets called when the plugin singleton is initialized, i.e. when the application has been started.
[virtual,const]	bool	**menu_activated**	(string symbol)	Gets called when a menu item is selected
	void	**register**	(int position, string name, string title)	Registers the plugin factory
	void	**register**	(int position, string name, string title, string icon)	Registers the plugin factory
[virtual]	void	**uninitialized**	(Dispatcher ptr dispatcher)	Gets called when the application shuts down and the plugin is unregistered

Deprecated methods (protected, public, static, non-static and constructors)

	void	**add_menu_entry**	(string symbol, string menu_name, string insert_pos, string title, bool sub_menu)	Use of this method is deprecated
	void	**create**		Use of this method is deprecated. Use _create instead
	void	**destroy**		Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**		Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**		Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

add_config_menu_item

Signature: void **add_config_menu_item** (string menu_name, string insert_pos, string title, string cname, string cvalue)

Description: Adds a configuration menu item

Menu items created this way will send a configuration request with 'cname' as the configuration parameter name and 'cvalue' as the configuration parameter value.

This method has been introduced in version 0.27.

add_menu_entry

(1) Signature: void **add_menu_entry** (string menu_name, string insert_pos)

Description: Specifies a separator

Call this method in the factory constructor to build the menu items that this plugin shall create. This specific call inserts a separator at the given position (insert_pos). The position uses abstract menu item paths and "menu_name" names the component that will be created. See AbstractMenu for a description of the path.

(2) Signature: void **add_menu_entry** (string symbol, string menu_name, string insert_pos, string title)

Description: Specifies a menu item

symbol:	The string to send to the plugin if the menu is triggered
menu_name:	The name of entry to create at the given position
insert_pos:	The position where to create the entry
title:	The title string for the item. The title can contain a keyboard shortcut in round braces after the title text, i.e. "My Menu Item(F12)"

Call this method in the factory constructor to build the menu items that this plugin shall create. This specific call inserts a menu item at the specified position (insert_pos). The position uses abstract menu item paths and "menu_name" names the component that will be created. See AbstractMenu for a description of the path. When the menu item is selected "symbol" is the string that is sent to the menu_activated callback (either the global one for the factory ot the one of the per-view plugin instance).

(3) Signature: void **add_menu_entry** (string symbol, string menu_name, string insert_pos, string title, bool sub_menu)

Description: Specifies a menu item or sub-menu

Use of this method is deprecated

Similar to the previous form of "add_menu_entry", but this version allows also to create sub-menus by setting the last parameter to "true".

With version 0.27 it's more convenient to use add_submenu.

add_menu_item_clone

Signature: void **add_menu_item_clone** (string symbol, string menu_name, string insert_pos, string copy_from)

Description: Specifies a menu item as a clone of another one

Using this method, a menu item can be made a clone of another entry (given as path by 'copy_from'). The new item will share the Action object with the original one, so manipulating the action will change both the original entry and the new entry.

This method has been introduced in version 0.27.

add_option

Signature: void **add_option** (string name, string default_value)

Description: Specifies configuration variables.

Call this method in the factory constructor to add configuration key/value pairs to the configuration repository. Without specifying configuration variables, the status of a plugin cannot be persisted.

Once the configuration variables are known, they can be retrieved on demand using "get_config" from MainWindow or listening to configure callbacks (either in the factory or the plugin instance). Configuration variables can be set using "set_config" from MainWindow. This scheme also works

without registering the configuration options, but doing so has the advantage that it is guaranteed that a variable with this keys exists and has the given default value initially.

add_submenu

Signature: void **add_submenu** (string menu_name, string insert_pos, string title)

Description: Specifies a menu item or sub-menu

This method has been introduced in version 0.27.

config_finalize

Signature: *[virtual]* void **config_finalize**

Description: Gets called after a set of configuration events has been sent

This method can be reimplemented and is called after a set of configuration events has been sent to the plugin factory singleton with configure. It can be used to set up user interfaces properly for example.

configure

Signature: *[virtual]* bool **configure** (string name, string value)

Description: Gets called for configuration events for the plugin singleton

name:	The configuration key
value:	The value of the configuration variable
Returns:	True to stop further processing

This method can be reimplemented to receive configuration events for the plugin singleton. Before a configuration can be received it must be registered by calling add_option in the plugin factories' constructor.

The implementation of this method may return true indicating that the configuration request will not be handled by further modules. It's more cooperative to return false which will make the system distribute the configuration request to other receivers as well.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

create_plugin

Signature: *[virtual,const]* new Plugin ptr **create_plugin** (Manager ptr manager, Dispatcher ptr dispatcher, LayoutView ptr view)

Description: Creates the plugin

manager:	The database manager object responsible for handling database transactions
dispatcher:	The reference to the MainWindow object
view:	The LayoutView that is plugin is created for
Returns:	The new Plugin implementation object

This is the basic functionality that the factory must provide. This method must create a plugin of the specific type.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

has_tool_entry=

Signature: void **has_tool_entry=** (bool f)

Description: Enables or disables the tool bar entry

Initially this property is set to true. This means that the plugin will have a visible entry in the toolbar. This property can be set to false to disable this feature. In that case, the title and icon given on registration will be ignored.

Python specific notes:
The object exposes a writable attribute 'has_tool_entry'. This is the setter.

initialized

Signature: *[virtual]* void **initialized** (Dispatcher ptr dispatcher)

Description: Gets called when the plugin singleton is initialized, i.e. when the application has been started.

dispatcher: The reference to the MainWindow object

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

menu_activated

Signature: *[virtual,const]* bool **menu_activated** (string symbol)

Description: Gets called when a menu item is selected

Usually, menu-triggered functionality is implemented in the per-view instance of the plugin. However, using this method it is possible to implement functionality globally for all plugin instances. The symbol is the string registered with the specific menu item in the add_menu_item call.

If this method was handling the menu event, it should return true. This indicates that the event will not be propagated to other plugins hence avoiding duplicate calls.

new

Signature: *[static]* new PluginFactory ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

register

(1) Signature: void **register** (int position, string name, string title)

Description: Registers the plugin factory

position: An integer that determines the order in which the plugins are created. The internal plugins use the values from 1000 to 50000.

name: The plugin name. This is an arbitrary string which should be unique. Hence it is recommended to use a unique prefix, i.e. "myplugin::ThePluginClass".

title: The title string which is supposed to appear in the tool bar and menu related to this plugin.

Registration of the plugin factory makes the object known to the system. Registration requires that the menu items have been set already. Hence it is recommended to put the registration at the end of the initialization method of the factory class.

(2) Signature: void **register** (int position, string name, string title, string icon)

Description: Registers the plugin factory

position: An integer that determines the order in which the plugins are created. The internal plugins use the values from 1000 to 50000.

name: The plugin name. This is an arbitrary string which should be unique. Hence it is recommended to use a unique prefix, i.e. "myplugin::ThePluginClass".

title: The title string which is supposed to appear in the tool bar and menu related to this plugin.

icon: The path to the icon that appears in the tool bar and menu related to this plugin.

This version also allows registering an icon for the tool bar.

Registration of the plugin factory makes the object known to the system. Registration requires that the menu items have been set already. Hence it is recommended to put the registration at the end of the initialization method of the factory class.

uninitialized

Signature: *[virtual]* void **uninitialized** (Dispatcher ptr dispatcher)

Description: Gets called when the application shuts down and the plugin is unregistered

dispatcher: The reference to the MainWindow object

This event can be used to free resources allocated with this factory singleton.

4.205. API reference - Class Plugin

Notation used in Ruby API documentation

Module: lay

Description: The plugin object

This class provides the actual plugin implementation. Each view gets its own instance of the plugin class. The plugin factory PluginFactory class must be specialized to provide a factory for new objects of the Plugin class. See the documentation there for details about the plugin mechanism and the basic concepts.

This class has been introduced in version 0.22.

Public constructors

new Plugin ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[virtual]	void	**activated**		Gets called when the plugin is activated (selected in the tool bar)
[virtual]	void	**config_finalize**		Sends the post-configuration request to the plugin
[virtual]	bool	**configure**	(string name, string value)	Sends configuration requests to the plugin
[virtual]	void	**deactivated**		Gets called when the plugin is deactivated and another plugin is activated
[virtual]	void	**drag_cancel**		Gets called on various occasions when a drag operation should be canceled
[virtual]	bool	**enter_event**	(bool prio)	Handles the enter event (mouse enters canvas area of view)
	void	**grab_mouse**		Redirects mouse events to this plugin, even if the plugin is not active.

[virtual,const]	bool	**has_tracking_position**		Gets a value indicating whether the plugin provides a tracking position
[virtual]	bool	**key_event**	(unsigned int key, unsigned int buttons)	Handles the key pressed event
[virtual]	bool	**leave_event**	(bool prio)	Handles the leave event (mouse leaves canvas area of view)
[virtual]	void	**menu_activated**	(string symbol)	Gets called when a custom menu item is selected
[virtual]	bool	**mouse_button_pressed_event**	(DPoint p, unsigned int buttons, bool prio)	Handles the mouse button pressed event
[virtual]	bool	**mouse_button_released**	(DPoint p, unsigned int buttons, bool prio)	Handles the mouse button release event
[virtual]	bool	**mouse_click_event**	(DPoint p, unsigned int buttons, bool prio)	Handles the mouse button click event (after the button has been released)
[virtual]	bool	**mouse_double_click_ev**	(DPoint p, unsigned int buttons, bool prio)	Handles the mouse button double-click event
[virtual]	bool	**mouse_moved_event**	(DPoint p, unsigned int buttons, bool prio)	Handles the mouse move event
	void	**set_cursor**	(int cursor_type)	Sets the cursor in the view area to the given type
[virtual,const]	DPoint	**tracking_position**		Gets the tracking position
	void	**ungrab_mouse**		Removes a mouse grab registered with grab_mouse.
[virtual]	void	**update**		Gets called when the view has changed
[virtual]	bool	**wheel_event**	(int delta, bool horizontal, DPoint p, unsigned int buttons, bool prio)	

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead

	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

activated

Signature: *[virtual]* void **activated**

Description: Gets called when the plugin is activated (selected in the tool bar)

config_finalize

Signature: *[virtual]* void **config_finalize**

Description: Sends the post-configuration request to the plugin

After all configuration parameters have been sent, 'config_finalize' is called to given the plugin a chance to update its internal state according to the new configuration.

configure

Signature: *[virtual]* bool **configure** (string name, string value)

Description: Sends configuration requests to the plugin

name:	The name of the configuration variable as registered in the plugin factory
value:	The value of the configuration variable

When a configuration variable is changed, the new value is reported to the plugin by calling the 'configure' method.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

deactivated

Signature: *[virtual]* void **deactivated**

Description: Gets called when the plugin is deactivated and another plugin is activated

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

drag_cancel

Signature: *[virtual]* void **drag_cancel**

Description: Gets called on various occasions when a drag operation should be canceled

If the plugin implements some press-and-drag or a click-and-drag operation, this callback should cancel this operation and return in some state waiting for a new mouse event.

enter_event

Signature: *[virtual]* bool **enter_event** (bool prio)

Description: Handles the enter event (mouse enters canvas area of view)

The behaviour of this callback is the same than for mouse_press_event, except that it is called when the mouse enters the canvas area. This method does not have a position nor button flags.

grab_mouse

Signature: void **grab_mouse**

Description: Redirects mouse events to this plugin, even if the plugin is not active.

has_tracking_position

Signature: *[virtual,const]* bool **has_tracking_position**

Description: Gets a value indicating whether the plugin provides a tracking position

The tracking position is shown in the lower-left corner of the layout window to indicate the current position. If this method returns true for the active service, the application will fetch the position by calling tracking_position rather than displaying the original mouse position.

This method has been added in version 0.27.6.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

key_event

Signature: *[virtual]* bool **key_event** (unsigned int key, unsigned int buttons)

Description: Handles the key pressed event

key:	The Qt key code of the key that was pressed
buttons:	A combination of the constants in the ButtonState class which codes both the mouse buttons and the key modifiers (.e. ShiftButton etc).
Returns:	True to terminate dispatcher

This method will called by the view on the active plugin when a button is pressed on the mouse.

If the plugin handles the event, it should return true to indicate that the event should not be processed further.

leave_event

Signature: *[virtual]* bool **leave_event** (bool prio)

Description: Handles the leave event (mouse leaves canvas area of view)

The behaviour of this callback is the same than for mouse_press_event, except that it is called when the mouse leaves the canvas area. This method does not have a position nor button flags.

menu_activated

Signature: *[virtual]* void **menu_activated** (string symbol)

Description: Gets called when a custom menu item is selected

When a menu item is clicked which was registered with the plugin factory, the plugin's 'menu_activated' method is called for the current view. The symbol registered for the menu item is passed in the 'symbol' argument.

mouse_button_pressed_event

Signature: *[virtual]* bool **mouse_button_pressed_event** (DPoint p, unsigned int buttons, bool prio)

Description: Handles the mouse button pressed event

p:	The point at which the button was pressed

buttons: A combination of the constants in the ButtonState class which codes both the mouse buttons and the key modifiers (.e. LeftButton, ShiftButton etc).

Returns: True to terminate dispatcher

This method will called by the view when a button is pressed on the mouse.

First, the plugins that grabbed the mouse with grab_mouse will receive this event with 'prio' set to true in the reverse order the plugins grabbed the mouse. The loop will terminate if one of the mouse event handlers returns true.

If that is not the case or no plugin has grabbed the mouse, the active plugin receives the mouse event with 'prio' set to true.

If no receiver accepted the mouse event by returning true, it is sent again to all plugins with 'prio' set to false. Again, the loop terminates if one of the receivers returns true. The second pass gives inactive plugins a chance to monitor the mouse and implement specific actions - i.e. displaying the current position.

This event is not sent immediately when the mouse button is pressed but when a signification movement for the mouse cursor away from the original position is detected. If the mouse button is released before that, a mouse_clicked_event is sent rather than a press-move-release sequence.

mouse_button_released_ever

Signature: *[virtual]* bool **mouse_button_released_event** (DPoint p, unsigned int buttons, bool prio)

Description: Handles the mouse button release event

The behaviour of this callback is the same than for mouse_press_event, except that it is called when the mouse button is released.

mouse_click_event

Signature: *[virtual]* bool **mouse_click_event** (DPoint p, unsigned int buttons, bool prio)

Description: Handles the mouse button click event (after the button has been released)

The behaviour of this callback is the same than for mouse_press_event, except that it is called when the mouse button has been released without moving it.

mouse_double_click_event

Signature: *[virtual]* bool **mouse_double_click_event** (DPoint p, unsigned int buttons, bool prio)

Description: Handles the mouse button double-click event

The behaviour of this callback is the same than for mouse_press_event, except that it is called when the mouse button has been double-clicked.

mouse_moved_event

Signature: *[virtual]* bool **mouse_moved_event** (DPoint p, unsigned int buttons, bool prio)

Description: Handles the mouse move event

The behaviour of this callback is the same than for mouse_press_event, except that it is called when the mouse is moved in the canvas area.

new

Signature: *[static]* new Plugin ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

set_cursor

Signature: void **set_cursor** (int cursor_type)

Description: Sets the cursor in the view area to the given type

Setting the cursor has an effect only inside event handlers, i.e. mouse_press_event. The cursor is not set permanently. Is is reset in the mouse move handler unless a button is pressed or the cursor is explicitly set again in the mouse_move_event.

The cursor type is one of the cursor constants in the Cursor class, i.e. 'CursorArrow' for the normal cursor.

tracking_position

Signature: *[virtual,const]* DPoint **tracking_position**

Description: Gets the tracking position

See has_tracking_position for details.

This method has been added in version 0.27.6.

ungrab_mouse

Signature: void **ungrab_mouse**

Description: Removes a mouse grab registered with grab_mouse.

update

Signature: *[virtual]* void **update**

Description: Gets called when the view has changed

This method is called in particular if the view has changed the visible rectangle, i.e. after zooming in or out or panning. This callback can be used to update any internal states that depend on the view's state.

wheel_event

Signature: *[virtual]* bool **wheel_event** (int delta, bool horizontal, DPoint p, unsigned int buttons, bool prio)

Description:

The behaviour of this callback is the same than for mouse_press_event, except that it is called when the mouse wheel is rotated. Additional parameters for this event are 'delta' (the rotation angle in units of 1/8th degree) and 'horizontal' which is true when the horizontal wheel was rotated and false if the vertical wheel was rotated.

4.206. API reference - Class Cursor

Notation used in Ruby API documentation

Module: lay

Description: The namespace for the cursor constants

This class defines the constants for the cursor setting (for example for class Plugin, method set_cursor). This class has been introduced in version 0.22.

Public constructors

new Cursor ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const Cursor other)	Assigns another object to self
[const]	new Cursor ptr	**dup**		Creates a copy of self

Public static methods and constants

int	**Arrow**	'Arrow cursor' constant
int	**Blank**	'Blank cursor' constant
int	**Busy**	'Busy state cursor' constant
int	**ClosedHand**	'Closed hand cursor' constant
int	**Cross**	'Cross cursor' constant
int	**Forbidden**	'Forbidden area cursor' constant
int	**IBeam**	'I beam (text insert) cursor' constant
int	**None**	'No cursor (default)' constant for set_cursor (resets cursor to default)

int	OpenHand	'Open hand cursor' constant
int	PointingHand	'Pointing hand cursor' constant
int	SizeAll	'Size all directions cursor' constant
int	SizeBDiag	'Backward diagonal resize cursor' constant
int	SizeFDiag	'Forward diagonal resize cursor' constant
int	SizeHor	'Horizontal resize cursor' constant
int	SizeVer	'Vertical resize cursor' constant
int	SplitH	'split_horizontal cursor' constant
int	SplitV	'Split vertical cursor' constant
int	UpArrow	'Upward arrow cursor' constant
int	Wait	'Waiting cursor' constant
int	WhatsThis	'Question mark cursor' constant

Deprecated methods (protected, public, static, non-static and constructors)

	void	create	Use of this method is deprecated. Use _create instead
	void	destroy	Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	is_const_object?	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

Arrow

Signature: *[static]* int **Arrow**

Description: 'Arrow cursor' constant

Python specific notes:
The object exposes a readable attribute 'Arrow'. This is the getter.

Blank

Signature: *[static]* int **Blank**

Description: 'Blank cursor' constant

Python specific notes:
The object exposes a readable attribute 'Blank'. This is the getter.

Busy

Signature: *[static]* int **Busy**

Description: 'Busy state cursor' constant

Python specific notes:
The object exposes a readable attribute 'Busy'. This is the getter.

ClosedHand	**Signature**: *[static]* int **ClosedHand** **Description**: 'Closed hand cursor' constant **Python specific notes:** The object exposes a readable attribute 'ClosedHand'. This is the getter.
Cross	**Signature**: *[static]* int **Cross** **Description**: 'Cross cursor' constant **Python specific notes:** The object exposes a readable attribute 'Cross'. This is the getter.
Forbidden	**Signature**: *[static]* int **Forbidden** **Description**: 'Forbidden area cursor' constant **Python specific notes:** The object exposes a readable attribute 'Forbidden'. This is the getter.
IBeam	**Signature**: *[static]* int **IBeam** **Description**: 'I beam (text insert) cursor' constant **Python specific notes:** The object exposes a readable attribute 'IBeam'. This is the getter.
None	**Signature**: *[static]* int **None** **Description**: 'No cursor (default)' constant for set_cursor (resets cursor to default) **Python specific notes:** This member is available as 'None_' in Python. The object exposes a readable attribute 'None_'. This is the getter.
OpenHand	**Signature**: *[static]* int **OpenHand** **Description**: 'Open hand cursor' constant **Python specific notes:** The object exposes a readable attribute 'OpenHand'. This is the getter.
PointingHand	**Signature**: *[static]* int **PointingHand** **Description**: 'Pointing hand cursor' constant **Python specific notes:** The object exposes a readable attribute 'PointingHand'. This is the getter.
SizeAll	**Signature**: *[static]* int **SizeAll** **Description**: 'Size all directions cursor' constant **Python specific notes:** The object exposes a readable attribute 'SizeAll'. This is the getter.
SizeBDiag	**Signature**: *[static]* int **SizeBDiag** **Description**: 'Backward diagonal resize cursor' constant **Python specific notes:** The object exposes a readable attribute 'SizeBDiag'. This is the getter.

SizeFDiag	**Signature**: *[static]* int **SizeFDiag** **Description**: 'Forward diagonal resize cursor' constant **Python specific notes:** The object exposes a readable attribute 'SizeFDiag'. This is the getter.
SizeHor	**Signature**: *[static]* int **SizeHor** **Description**: 'Horizontal resize cursor' constant **Python specific notes:** The object exposes a readable attribute 'SizeHor'. This is the getter.
SizeVer	**Signature**: *[static]* int **SizeVer** **Description**: 'Vertical resize cursor' constant **Python specific notes:** The object exposes a readable attribute 'SizeVer'. This is the getter.
SplitH	**Signature**: *[static]* int **SplitH** **Description**: 'split_horizontal cursor' constant **Python specific notes:** The object exposes a readable attribute 'SplitH'. This is the getter.
SplitV	**Signature**: *[static]* int **SplitV** **Description**: 'Split vertical cursor' constant **Python specific notes:** The object exposes a readable attribute 'SplitV'. This is the getter.
UpArrow	**Signature**: *[static]* int **UpArrow** **Description**: 'Upward arrow cursor' constant **Python specific notes:** The object exposes a readable attribute 'UpArrow'. This is the getter.
Wait	**Signature**: *[static]* int **Wait** **Description**: 'Waiting cursor' constant **Python specific notes:** The object exposes a readable attribute 'Wait'. This is the getter.
WhatsThis	**Signature**: *[static]* int **WhatsThis** **Description**: 'Question mark cursor' constant **Python specific notes:** The object exposes a readable attribute 'WhatsThis'. This is the getter.
_create	**Signature**: void **_create** **Description**: Ensures the C++ object is created Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const Cursor other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

	Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
destroyed?	**Signature**: *[const]* bool **destroyed?** **Description**: Returns a value indicating whether the object was already destroyed Use of this method is deprecated. Use _destroyed? instead This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
dup	**Signature**: *[const]* new Cursor ptr **dup** **Description**: Creates a copy of self **Python specific notes:** This method also implements '__copy__' and '__deepcopy__'.
is_const_object?	**Signature**: *[const]* bool **is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.
new	**Signature**: *[static]* new Cursor ptr **new** **Description**: Creates a new object of this class **Python specific notes:** This method is the default initializer of the object.

4.207. API reference - Class ButtonState

Notation used in Ruby API documentation

Module: lay

Description: The namespace for the button state flags in the mouse events of the Plugin class.

This class defines the constants for the button state. In the event handler, the button state is indicated by a bitwise combination of these constants. See Plugin for further details. This class has been introduced in version 0.22.

Public constructors

new ButtonState ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const ButtonState other)	Assigns another object to self
[const]	new ButtonState ptr	**dup**		Creates a copy of self

Public static methods and constants

int	**AltKey**	Indicates that the Alt key is pressed
int	**ControlKey**	Indicates that the Control key is pressed
int	**LeftButton**	Indicates that the left mouse button is pressed
int	**MidButton**	Indicates that the middle mouse button is pressed
int	**RightButton**	Indicates that the right mouse button is pressed
int	**ShiftKey**	Indicates that the Shift key is pressed

Deprecated methods (protected, public, static, non-static and constructors)

void	**create**	Use of this method is deprecated. Use _create instead

	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

AltKey

Signature: *[static]* int **AltKey**

Description: Indicates that the Alt key is pressed

This constant is combined with other constants within ButtonState

Python specific notes:
The object exposes a readable attribute 'AltKey'. This is the getter.

ControlKey

Signature: *[static]* int **ControlKey**

Description: Indicates that the Control key is pressed

This constant is combined with other constants within ButtonState

Python specific notes:
The object exposes a readable attribute 'ControlKey'. This is the getter.

LeftButton

Signature: *[static]* int **LeftButton**

Description: Indicates that the left mouse button is pressed

This constant is combined with other constants within ButtonState

Python specific notes:
The object exposes a readable attribute 'LeftButton'. This is the getter.

MidButton

Signature: *[static]* int **MidButton**

Description: Indicates that the middle mouse button is pressed

This constant is combined with other constants within ButtonState

Python specific notes:
The object exposes a readable attribute 'MidButton'. This is the getter.

RightButton

Signature: *[static]* int **RightButton**

Description: Indicates that the right mouse button is pressed

This constant is combined with other constants within ButtonState

Python specific notes:
The object exposes a readable attribute 'RightButton'. This is the getter.

ShiftKey

Signature: *[static]* int **ShiftKey**

Description: Indicates that the Shift key is pressed

This constant is combined with other constants within ButtonState

Python specific notes:
The object exposes a readable attribute 'ShiftKey'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const ButtonState other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new ButtonState ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new ButtonState ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

4.208. API reference - Class KeyCode

Notation used in Ruby API documentation

Module: lay

Description: The namespace for the some key codes.

This namespace defines some key codes understood by built-in LayoutView components. When compiling with Qt, these codes are compatible with Qt's key codes. The key codes are intended to be used when directly interfacing with LayoutView in non-Qt-based environments.

This class has been introduced in version 0.28.

Public constructors

new KeyCode ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const KeyCode other)	Assigns another object to self
[const]	new KeyCode ptr	**dup**		Creates a copy of self

Public static methods and constants

int	**Backspace**	Indicates the Backspace key
int	**Backtab**	Indicates the Backtab key
int	**Delete**	Indicates the Delete key
int	**Down**	Indicates the Down key
int	**End**	Indicates the End key
int	**Enter**	Indicates the Enter key
int	**Escape**	Indicates the Escape key
int	**Home**	Indicates the Home key

	int	**Insert**	Indicates the Insert key
	int	**Left**	Indicates the Left key
	int	**PageDown**	Indicates the PageDown key
	int	**PageUp**	Indicates the PageUp key
	int	**Return**	Indicates the Return key
	int	**Right**	Indicates the Right key
	int	**Tab**	Indicates the Tab key
	int	**Up**	Indicates the Up key

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

Backspace

Signature: *[static]* int **Backspace**

Description: Indicates the Backspace key

Python specific notes:
The object exposes a readable attribute 'Backspace'. This is the getter.

Backtab

Signature: *[static]* int **Backtab**

Description: Indicates the Backtab key

Python specific notes:
The object exposes a readable attribute 'Backtab'. This is the getter.

Delete

Signature: *[static]* int **Delete**

Description: Indicates the Delete key

Python specific notes:
The object exposes a readable attribute 'Delete'. This is the getter.

Down

Signature: *[static]* int **Down**

Description: Indicates the Down key

Python specific notes:
The object exposes a readable attribute 'Down'. This is the getter.

End

Signature: *[static]* int **End**

Description: Indicates the End key

Python specific notes:
The object exposes a readable attribute 'End'. This is the getter.

Enter

Signature: *[static]* int **Enter**

Description: Indicates the Enter key

Python specific notes:
The object exposes a readable attribute 'Enter'. This is the getter.

Escape

Signature: *[static]* int **Escape**

Description: Indicates the Escape key

Python specific notes:
The object exposes a readable attribute 'Escape'. This is the getter.

Home

Signature: *[static]* int **Home**

Description: Indicates the Home key

Python specific notes:
The object exposes a readable attribute 'Home'. This is the getter.

Insert

Signature: *[static]* int **Insert**

Description: Indicates the Insert key

Python specific notes:
The object exposes a readable attribute 'Insert'. This is the getter.

Left

Signature: *[static]* int **Left**

Description: Indicates the Left key

Python specific notes:
The object exposes a readable attribute 'Left'. This is the getter.

PageDown

Signature: *[static]* int **PageDown**

Description: Indicates the PageDown key

Python specific notes:
The object exposes a readable attribute 'PageDown'. This is the getter.

PageUp

Signature: *[static]* int **PageUp**

Description: Indicates the PageUp key

Python specific notes:
The object exposes a readable attribute 'PageUp'. This is the getter.

Return

Signature: *[static]* int **Return**

Description: Indicates the Return key

Python specific notes:
The object exposes a readable attribute 'Return'. This is the getter.

Right

Signature: *[static]* int **Right**

Description: Indicates the Right key

Python specific notes:
The object exposes a readable attribute 'Right'. This is the getter.

Tab

Signature: *[static]* int **Tab**

Description: Indicates the Tab key

Python specific notes:
The object exposes a readable attribute 'Tab'. This is the getter.

Up

Signature: *[static]* int **Up**

Description: Indicates the Up key

Python specific notes:
The object exposes a readable attribute 'Up'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const KeyCode other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new KeyCode ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new KeyCode ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

4.209. API reference - Class Dispatcher

Notation used in Ruby API documentation

Module: lay

Description: Root of the configuration space in the plugin context and menu dispatcher

This class provides access to the root configuration space in the context of plugin programming. You can use this class to obtain configuration parameters from the configuration tree during plugin initialization. However, the preferred way of plugin configuration is through Plugin#configure.

Currently, the application object provides an identical entry point for configuration modification. For example, "Application::instance.set_config" is identical to "Dispatcher::instance.set_config". Hence there is little motivation for the Dispatcher class currently and this interface may be modified or removed in the future. This class has been introduced in version 0.25 as 'PluginRoot'. It is renamed and enhanced as 'Dispatcher' in 0.27.

Public constructors

new Dispatcher ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**clear_config**		Clears the configuration parameters
	void	**commit_config**		Commits the configuration settings
	variant	**get_config**	(string name)	Gets the value of a local configuration parameter
	string[]	**get_config_names**		Gets the configuration parameter names
	bool	**read_config**	(string file_name)	Reads the configuration from a file
	void	**set_config**	(string name, string value)	Set a local configuration parameter with the given name to the given value
	bool	**write_config**	(string file_name)	Writes configuration to a file

Public static methods and constants

Dispatcher ptr	instance	Gets the singleton instance of the Dispatcher object

Deprecated methods (protected, public, static, non-static and constructors)

	void	create	Use of this method is deprecated. Use _create instead
	void	destroy	Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	is_const_object?	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void _**create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void _**destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool _**destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool _**is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void _**manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

clear_config

Signature: void **clear_config**

Description: Clears the configuration parameters

commit_config

Signature: void **commit_config**

Description: Commits the configuration settings

Some configuration options are queued for performance reasons and become active only after 'commit_config' has been called. After a sequence of set_config calls, this method should be called to activate the settings made by these calls.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

get_config

Signature: variant **get_config** (string name)

Description: Gets the value of a local configuration parameter

name:	The name of the configuration parameter whose value shall be obtained (a string)
Returns:	The value of the parameter or nil if there is no such parameter

get_config_names

Signature: string[] **get_config_names**

Description: Gets the configuration parameter names

Returns: A list of configuration parameter names

This method returns the names of all known configuration parameters. These names can be used to get and set configuration parameter values.

instance

Signature: *[static]* Dispatcher ptr **instance**

Description: Gets the singleton instance of the Dispatcher object

Returns: The instance

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new Dispatcher ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

read_config

Signature: bool **read_config** (string file_name)

Description: Reads the configuration from a file

Returns: A value indicating whether the operation was successful

This method silently does nothing, if the config file does not exist. If it does and an error occurred, the error message is printed on stderr. In both cases, false is returned.

set_config

Signature: void **set_config** (string name, string value)

Description: Set a local configuration parameter with the given name to the given value

name: The name of the configuration parameter to set

value: The value to which to set the configuration parameter

This method sets a configuration parameter with the given name to the given value. Values can only be strings. Numerical values have to be converted into strings first. Local configuration parameters override global configurations for this specific view. This allows for example to override global settings of background colors. Any local settings are not written to the configuration file.

write_config

Signature: bool **write_config** (string file_name)

Description: Writes configuration to a file

Returns: A value indicating whether the operation was successful

If the configuration file cannot be written, false is returned but no exception is thrown.

4.210. API reference - Class BrowserDialog

Notation used in Ruby API documentation

Module: lay

Description: A HTML display and browser dialog

Class hierarchy: BrowserDialog » QDialog » QWidget » QObject

The browser dialog displays HTML code in a browser panel. The HTML code is delivered through a separate object of class BrowserSource which acts as a "server" for a specific kind of URL scheme. Whenever the browser sees a URL starting with "int:" it will ask the connected BrowserSource object for the HTML code of that page using its 'get' method. The task of the BrowserSource object is to format the data requested in HTML and deliver it.

One use case for that class is the implementation of rich data browsers for structured information. In a simple scenario, the browser dialog can be instantiated with a static HTML page. In that case, only the content of that page is shown.

Here's a simple example:

```
html = "<html><body>Hello, world!</body></html>"
RBA::BrowserDialog::new(html).exec
```

And that is an example for the use case with a BrowserSource as the "server":

```
class MySource < RBA::BrowserSource
  def get(url)
    if (url =~ /b.html$/)
      return "<html><body>The second page</body></html>"
    else
      return "<html><body>The first page with a <a href='int:b.html'>link</a></body></html>"
    end
  end
end

source = MySource::new
RBA::BrowserDialog::new(source).exec
```

Public constructors

new BrowserDialog ptr	**new**	(BrowserSource ptr source)	Creates a HTML browser window with a BrowserSource as the source of HTML code
new BrowserDialog ptr	**new**	(string html)	Creates a HTML browser window with a static HTML content
new BrowserDialog ptr	**new**	(QWidget ptr parent, BrowserSource ptr source)	Creates a HTML browser window with a BrowserSource as the source of HTML code
new BrowserDialog ptr	**new**	(QWidget ptr parent, string html)	Creates a HTML browser window with a static HTML content

Public methods

void	**_create**	Ensures the C++ object is created
void	**_destroy**	Explicitly destroys the object

[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**caption=**	(string caption)	Sets the caption of the window
	int	**execute**		Executes the HTML browser dialog as a modal window
	void	**home=**	(string home_url)	Sets the browser's initial and current URL which is selected if the "home" location is chosen
	void	**label=**	(string label)	Sets the label text
	void	**load**	(string url)	Loads the given URL into the browser dialog
	void	**reload**		Reloads the current page
	void	**resize**	(int width, int height)	Sets the size of the dialog window
	void	**search**	(string search_item)	Issues a search request using the given search item and the search URL specified with set_search_url
	void	**set_search_url**	(string url, string query_item)	Enables the search field and specifies the search URL generated for a search
	void	**source=**	(BrowserSource ptr source)	Connects to a source object

Deprecated methods (protected, public, static, non-static and constructors)

[virtual]	void	**closed**		Use of this method is deprecated
	int	**exec**		Use of this method is deprecated. Use execute instead
	void	**set_caption**	(string caption)	Use of this method is deprecated. Use caption= instead
	void	**set_home**	(string home_url)	Use of this method is deprecated. Use home= instead
	void	**set_size**	(int width, int height)	Use of this method is deprecated. Use resize instead
	void	**set_source**	(BrowserSource ptr source)	Use of this method is deprecated. Use source= instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

caption=

Signature: void **caption=** (string caption)

Description: Sets the caption of the window

Python specific notes:
The object exposes a writable attribute 'caption'. This is the setter.

closed

Signature: *[virtual]* void **closed**

Description: Callback when the dialog is closed

Use of this method is deprecated

This callback can be reimplemented to implement cleanup functionality when the dialog is closed.

exec

Signature: int **exec**

Description: Executes the HTML browser dialog as a modal window

Use of this method is deprecated. Use execute instead

Python specific notes:
This attribute is available as 'exec_' in Python.

execute

Signature: int **execute**

Description: Executes the HTML browser dialog as a modal window

Python specific notes:
This attribute is available as 'exec_' in Python.

home=

Signature: void **home=** (string home_url)

Description: Sets the browser's initial and current URL which is selected if the "home" location is chosen

The home URL is the one shown initially and the one which is selected when the "home" button is pressed. The default location is "int:/index.html".

Python specific notes:
The object exposes a writable attribute 'home'. This is the setter.

label=

Signature: void **label=** (string label)

Description: Sets the label text

The label is shown left of the navigation buttons. By default, no label is specified.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'label'. This is the setter.

load

Signature: void **load** (string url)

Description: Loads the given URL into the browser dialog

Typically the URL has the "int:" scheme so the HTML code is taken from the BrowserSource object.

new

(1) Signature: *[static]* new BrowserDialog ptr **new** (BrowserSource ptr source)

Description: Creates a HTML browser window with a BrowserSource as the source of HTML code

This method has been introduced in version 0.23.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new BrowserDialog ptr **new** (string html)

Description: Creates a HTML browser window with a static HTML content

This method has been introduced in version 0.23.

Python specific notes:

This method is the default initializer of the object.

(3) Signature: *[static]* new BrowserDialog ptr **new** (QWidget ptr parent, BrowserSource ptr source)

Description: Creates a HTML browser window with a BrowserSource as the source of HTML code

This method variant with a parent argument has been introduced in version 0.24.2.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new BrowserDialog ptr **new** (QWidget ptr parent, string html)

Description: Creates a HTML browser window with a static HTML content

This method variant with a parent argument has been introduced in version 0.24.2.

Python specific notes:
This method is the default initializer of the object.

reload

Signature: void **reload**

Description: Reloads the current page

resize

Signature: void **resize** (int width, int height)

Description: Sets the size of the dialog window

search

Signature: void **search** (string search_item)

Description: Issues a search request using the given search item and the search URL specified with set_search_url

See set_search_url for a description of the search mechanism.

set_caption

Signature: void **set_caption** (string caption)

Description: Sets the caption of the window

Use of this method is deprecated. Use caption= instead

Python specific notes:
The object exposes a writable attribute 'caption'. This is the setter.

set_home

Signature: void **set_home** (string home_url)

Description: Sets the browser's initial and current URL which is selected if the "home" location is chosen

Use of this method is deprecated. Use home= instead

The home URL is the one shown initially and the one which is selected when the "home" button is pressed. The default location is "int:/index.html".

Python specific notes:
The object exposes a writable attribute 'home'. This is the setter.

set_search_url

Signature: void **set_search_url** (string url, string query_item)

Description: Enables the search field and specifies the search URL generated for a search

If a search URL is set, the search box right to the navigation bar will be enabled. When a text is entered into the search box, the browser will navigate to an URL composed of the search URL, the search item and the search text, i.e. "myurl?item=search_text".

This method has been introduced in version 0.23.

set_size

Signature: void **set_size** (int width, int height)

Description: Sets the size of the dialog window

Use of this method is deprecated. Use resize instead

set_source

Signature: void **set_source** (BrowserSource ptr source)

Description: Connects to a source object

Use of this method is deprecated. Use source= instead

Setting the source should be the first thing done after the BrowserDialog object is created. It will not have any effect after the browser has loaded the first page. In particular, home= should be called after the source was set.

Python specific notes:
The object exposes a writable attribute 'source'. This is the setter.

source=

Signature: void **source=** (BrowserSource ptr source)

Description: Connects to a source object

Setting the source should be the first thing done after the BrowserDialog object is created. It will not have any effect after the browser has loaded the first page. In particular, home= should be called after the source was set.

Python specific notes:
The object exposes a writable attribute 'source'. This is the setter.

4.211. API reference - Class BrowserSource

Notation used in Ruby API documentation

Module: lay

Description: The BrowserDialog's source for "int" URL's

The source object basically acts as a "server" for special URL's using "int" as the scheme. Classes that want to implement such functionality must derive from BrowserSource and reimplement the get method. This method is supposed to deliver a HTML page for the given URL.

Alternatively to implementing this functionality, a source object may be instantiated using the constructor with a HTML code string. This will create a source object that simply displays the given string as the initial and only page.

Public constructors

new BrowserSource ptr	**new**	(string html)	Constructs a BrowserSource object with a default HTML string

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const BrowserSource other)	Assigns another object to self
[const]	new BrowserSource ptr	**dup**		Creates a copy of self
[virtual]	string	**get**	(string url)	Gets the HTML code for a given "int" URL.
	QImage	**get_image**	(string url)	Gets the image object for a specific URL
	string	**next_topic**	(string url)	Gets the next topic URL from a given URL
	string	**prev_topic**	(string url)	Gets the previous topic URL from a given URL

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**		Use of this method is deprecated. Use _create instead

	void	destroy		Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?		Use of this method is deprecated. Use _destroyed? instead
[const]	bool	is_const_object?		Use of this method is deprecated. Use _is_const_object? instead
[static]	new BrowserSource ptr	new_html	(string html)	Use of this method is deprecated. Use new instead

Detailed description

_create

Signature: void _**create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void _**destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool _**destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool _**is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void _**manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void _**unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the

reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const BrowserSource other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new BrowserSource ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

get

Signature: *[virtual]* string **get** (string url)

Description: Gets the HTML code for a given "int" URL.

If this method returns an empty string, the browser will not be set to a new location. This allows implementing any functionality behind such links. If the method returns a string, the content of this string is displayed in the HTML browser page.

get_image

Signature: QImage **get_image** (string url)

Description: Gets the image object for a specific URL

This method has been introduced in version 0.28.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

	This method returns true, if self is a const reference. In that case, only const methods may be called on self.
new	**Signature**: *[static]* new BrowserSource ptr **new** (string html) **Description**: Constructs a BrowserSource object with a default HTML string The default HTML string is sent when no specific implementation is provided. **Python specific notes:** This method is the default initializer of the object.
new_html	**Signature**: *[static]* new BrowserSource ptr **new_html** (string html) **Description**: Constructs a BrowserSource object with a default HTML string Use of this method is deprecated. Use new instead The default HTML string is sent when no specific implementation is provided. **Python specific notes:** This method is the default initializer of the object.
next_topic	**Signature**: string **next_topic** (string url) **Description**: Gets the next topic URL from a given URL An empty string will be returned if no next topic is available. This method has been introduced in version 0.28.
prev_topic	**Signature**: string **prev_topic** (string url) **Description**: Gets the previous topic URL from a given URL An empty string will be returned if no previous topic is available. This method has been introduced in version 0.28.

4.212. API reference - Class BrowserPanel

Notation used in Ruby API documentation

Module: lay

Description: A HTML display and browser widget

Class hierarchy: BrowserPanel » QWidget » QObject

This widget provides the functionality of BrowserDialog within a widget. It can be embedded into other dialogs. For details about the use model of this class see BrowserDialog.

This class has been introduced in version 0.25.

Public constructors

new BrowserPanel ptr	**new**	(QWidget ptr parent, BrowserSource ptr source)	Creates a HTML browser widget with a BrowserSource as the source of HTML code
new BrowserPanel ptr	**new**	(QWidget ptr parent)	Creates a HTML browser widget

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**home=**	(string home_url)	Sets the browser widget's initial and current URL which is selected if the "home" location is chosen
	void	**label=**	(string label)	Sets the label text
	void	**load**	(string url)	Loads the given URL into the browser widget
	void	**reload**		Reloads the current page
	void	**search**	(string search_item)	Issues a search request using the given search item and the search URL specified with set_search_url
	void	**set_search_url**	(string url, string query_item)	Enables the search field and specifies the search URL generated for a search
	void	**source=**	(BrowserSource ptr source)	Connects to a source object

[const]	string	**url**	Gets the URL currently shown

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

home=

Signature: void **home=** (string home_url)

Description: Sets the browser widget's initial and current URL which is selected if the "home" location is chosen

The home URL is the one shown initially and the one which is selected when the "home" button is pressed. The default location is "int:/index.html".

Python specific notes:
The object exposes a writable attribute 'home'. This is the setter.

label=

Signature: void **label=** (string label)

Description: Sets the label text

The label is shown left of the navigation buttons. By default, no label is specified.

Python specific notes:
The object exposes a writable attribute 'label'. This is the setter.

load

Signature: void **load** (string url)

Description: Loads the given URL into the browser widget

Typically the URL has the "int:" scheme so the HTML code is taken from the BrowserSource object.

new

(1) Signature: *[static]* new BrowserPanel ptr **new** (QWidget ptr parent, BrowserSource ptr source)

Description: Creates a HTML browser widget with a BrowserSource as the source of HTML code

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new BrowserPanel ptr **new** (QWidget ptr parent)

Description: Creates a HTML browser widget

Python specific notes:
This method is the default initializer of the object.

reload

Signature: void **reload**

Description: Reloads the current page

search

Signature: void **search** (string search_item)

Description: Issues a search request using the given search item and the search URL specified with set_search_url

See search_url= for a description of the search mechanism.

set_search_url

Signature: void **set_search_url** (string url, string query_item)

Description: Enables the search field and specifies the search URL generated for a search

If a search URL is set, the search box right to the navigation bar will be enabled. When a text is entered into the search box, the browser will navigate to an URL composed of the search URL, the search item and the search text, i.e. "myurl?item=search_text".

source=

Signature: void **source=** (BrowserSource ptr source)

Description: Connects to a source object

Setting the source should be the first thing done after the BrowserDialog object is created. It will not have any effect after the browser has loaded the first page. In particular, home= should be called after the source was set.

Python specific notes:

The object exposes a writable attribute 'source'. This is the setter.

url

Signature: *[const]* string **url**

Description: Gets the URL currently shown

4.213. API reference - Class InputDialog

Notation used in Ruby API documentation

Module: lay

Description: Various methods to open a dialog requesting data entry

This class provides some basic dialogs to enter a single value. Values can be strings floating-point values, integer values or an item from a list. This functionality is provided through the static (class) methods ask_...

Here are some examples:

```
# get a double value between -10 and 10 (initial value is 0):
v = RBA::InputDialog::ask_double_ex("Dialog Title", "Enter the value here:", 0, -10, 10, 1)
# get an item from a list:
v = RBA::InputDialog::ask_item("Dialog Title", "Select one:", [ "item 1", "item 2", "item 3" ], 1)
```

All these examples return the "nil" value if "Cancel" is pressed.

If you have enabled the Qt binding, you can use QInputDialog directly.

Public constructors

new InputDialog ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const InputDialog other)	Assigns another object to self
[const]	new InputDialog ptr	**dup**		Creates a copy of self

Public static methods and constants

variant	**ask_double**	(string title, string label, double value, int digits)		Open an input dialog requesting a floating-point value

	variant	**ask_double_ex**	(string title, string label, double value, double min, double max, int digits)	Open an input dialog requesting a floating-point value with enhanced capabilities
	variant	**ask_int**	(string title, string label, int value)	Open an input dialog requesting an integer value
	variant	**ask_int_ex**	(string title, string label, int value, int min, int max, int step)	Open an input dialog requesting an integer value with enhanced capabilities
	variant	**ask_item**	(string title, string label, string[] items, int value)	Open an input dialog requesting an item from a list
	variant	**ask_string**	(string title, string label, string value)	Open an input dialog requesting a string
	variant	**ask_string_passwo**	(string title, string label, string value)	Open an input dialog requesting a string without showing the actual characters entered

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**		Use of this method is deprecated. Use _create instead
	void	**destroy**		Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**		Use of this method is deprecated. Use _destroyed? instead
[static]	DoubleValue	**get_double**	(string title, string label, double value, int digits)	Use of this method is deprecated
[static]	DoubleValue	**get_double_ex**	(string title, string label, double value, double min, double max, int digits)	Use of this method is deprecated
[static]	IntValue	**get_int**	(string title, string label, int value)	Use of this method is deprecated

[static]	IntValue	**get_int_ex**	(string title, string label, int value, int min, int max, int step)	Use of this method is deprecated
[static]	StringValue	**get_item**	(string title, string label, string[] items, int value)	Use of this method is deprecated
[static]	StringValue	**get_string**	(string title, string label, string value)	Use of this method is deprecated
[static]	StringValue	**get_string_password**	(string title, string label, string value)	Use of this method is deprecated
[const]	bool	**is_const_object?**		Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known

not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

ask_double

Signature: *[static]* variant **ask_double** (string title, string label, double value, int digits)

Description: Open an input dialog requesting a floating-point value

title:	The title to display for the dialog
label:	The label text to display for the dialog
value:	The initial value for the input field
digits:	The number of digits allowed
Returns:	The value entered if "Ok" was pressed or nil if "Cancel" was pressed

This method has been introduced in 0.22 and is somewhat easier to use than the get_.. equivalent.

ask_double_ex

Signature: *[static]* variant **ask_double_ex** (string title, string label, double value, double min, double max, int digits)

Description: Open an input dialog requesting a floating-point value with enhanced capabilities

title:	The title to display for the dialog
label:	The label text to display for the dialog
value:	The initial value for the input field
min:	The minimum value allowed
max:	The maximum value allowed
digits:	The number of digits allowed
Returns:	The value entered if "Ok" was pressed or nil if "Cancel" was pressed

This method has been introduced in 0.22 and is somewhat easier to use than the get_.. equivalent.

ask_int

Signature: *[static]* variant **ask_int** (string title, string label, int value)

Description: Open an input dialog requesting an integer value

title:	The title to display for the dialog
label:	The label text to display for the dialog
value:	The initial value for the input field
Returns:	The value entered if "Ok" was pressed or nil if "Cancel" was pressed

This method has been introduced in 0.22 and is somewhat easier to use than the get_.. equivalent.

ask_int_ex

Signature: *[static]* variant **ask_int_ex** (string title, string label, int value, int min, int max, int step)

Description: Open an input dialog requesting an integer value with enhanced capabilities

title:	The title to display for the dialog
label:	The label text to display for the dialog
value:	The initial value for the input field
min:	The minimum value allowed
max:	The maximum value allowed
step:	The step size for the spin buttons
Returns:	The value entered if "Ok" was pressed or nil if "Cancel" was pressed

This method has been introduced in 0.22 and is somewhat easier to use than the get_.. equivalent.

ask_item

Signature: *[static]* variant **ask_item** (string title, string label, string[] items, int value)

Description: Open an input dialog requesting an item from a list

title:	The title to display for the dialog
label:	The label text to display for the dialog
items:	The list of items to show in the selection element
selection:	The initial selection (index of the element selected initially)
Returns:	The string of the item selected if "Ok" was pressed or nil if "Cancel" was pressed

This method has been introduced in 0.22 and is somewhat easier to use than the get_.. equivalent.

ask_string

Signature: *[static]* variant **ask_string** (string title, string label, string value)

Description: Open an input dialog requesting a string

title:	The title to display for the dialog
label:	The label text to display for the dialog
value:	The initial value for the input field
Returns:	The string entered if "Ok" was pressed or nil if "Cancel" was pressed

This method has been introduced in 0.22 and is somewhat easier to use than the get_.. equivalent.

ask_string_password

Signature: *[static]* variant **ask_string_password** (string title, string label, string value)

Description: Open an input dialog requesting a string without showing the actual characters entered

title:	The title to display for the dialog
label:	The label text to display for the dialog
value:	The initial value for the input field
Returns:	The string entered if "Ok" was pressed or nil if "Cancel" was pressed

This method has been introduced in 0.22 and is somewhat easier to use than the get_.. equivalent.

assign

Signature: void **assign** (const InputDialog other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new InputDialog ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

get_double

Signature: *[static]* DoubleValue **get_double** (string title, string label, double value, int digits)

Description: Open an input dialog requesting a floating-point value

title:	The title to display for the dialog
label:	The label text to display for the dialog
value:	The initial value for the input field
digits:	The number of digits allowed
Returns:	A DoubleValue object with has_value? set to true, if "Ok" was pressed and the value given in its value attribute

Use of this method is deprecated

Starting from 0.22, this method is deprecated and it is recommended to use the ask_... equivalent.

get_double_ex

Signature: *[static]* DoubleValue **get_double_ex** (string title, string label, double value, double min, double max, int digits)

Description: Open an input dialog requesting a floating-point value with enhanced capabilities

title:	The title to display for the dialog
label:	The label text to display for the dialog
value:	The initial value for the input field
min:	The minimum value allowed
max:	The maximum value allowed
digits:	The number of digits allowed

Returns: A DoubleValue object with has_value? set to true, if "Ok" was pressed and the value given in its value attribute

Use of this method is deprecated

Starting from 0.22, this method is deprecated and it is recommended to use the ask_... equivalent.

get_int

Signature: *[static]* IntValue **get_int** (string title, string label, int value)

Description: Open an input dialog requesting an integer value

title: The title to display for the dialog

label: The label text to display for the dialog

value: The initial value for the input field

Returns: A IntValue object with has_value? set to true, if "Ok" was pressed and the value given in its value attribute

Use of this method is deprecated

Starting from 0.22, this method is deprecated and it is recommended to use the ask_... equivalent.

get_int_ex

Signature: *[static]* IntValue **get_int_ex** (string title, string label, int value, int min, int max, int step)

Description: Open an input dialog requesting an integer value with enhanced capabilities

title: The title to display for the dialog

label: The label text to display for the dialog

value: The initial value for the input field

min: The minimum value allowed

max: The maximum value allowed

step: The step size for the spin buttons

Returns: A IntValue object with has_value? set to true, if "Ok" was pressed and the value given in its value attribute

Use of this method is deprecated

Starting from 0.22, this method is deprecated and it is recommended to use the ask_... equivalent.

get_item

Signature: *[static]* StringValue **get_item** (string title, string label, string[] items, int value)

Description: Open an input dialog requesting an item from a list

title: The title to display for the dialog

label: The label text to display for the dialog

items: The list of items to show in the selection element

selection: The initial selection (index of the element selected initially)

Returns: A StringValue object with has_value? set to true, if "Ok" was pressed and the value given in its value attribute

Use of this method is deprecated

Starting from 0.22, this method is deprecated and it is recommended to use the ask_... equivalent.

get_string

Signature: *[static]* StringValue **get_string** (string title, string label, string value)

Description: Open an input dialog requesting a string

title: The title to display for the dialog

label: The label text to display for the dialog

value: The initial value for the input field

Returns: A StringValue object with has_value? set to true, if "Ok" was pressed and the value given in its value attribute

Use of this method is deprecated

Starting from 0.22, this method is deprecated and it is recommended to use the ask_... equivalent.

get_string_password

Signature: *[static]* StringValue **get_string_password** (string title, string label, string value)

Description: Open an input dialog requesting a string without showing the actual characters entered

title: The title to display for the dialog

label: The label text to display for the dialog

value: The initial value for the input field

Returns: A StringValue object with has_value? set to true, if "Ok" was pressed and the value given in its value attribute

Use of this method is deprecated

Starting from 0.22, this method is deprecated and it is recommended to use the ask_... equivalent.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new InputDialog ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

4.214. API reference - Class FileDialog

Notation used in Ruby API documentation

Module: lay

Description: Various methods to request a file name

This class provides some basic dialogs to select a file or directory. This functionality is provided through the static (class) methods ask_...

Here are some examples:

```
# get an existing directory:
v = RBA::FileDialog::ask_existing_dir("Dialog Title", ".")
# get multiple files:
v = RBA::FileDialog::ask_open_file_names("Title", ".", "All files (*)")
# ask for one file name to save a file:
v = RBA::FileDialog::ask_save_file_name("Title", ".", "All files (*)")
```

All these examples return the "nil" value if "Cancel" is pressed.

If you have enabled the Qt binding, you can use QFileDialog directly.

Public constructors

new FileDialog ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const FileDialog other)	Assigns another object to self
[const]	new FileDialog ptr	**dup**		Creates a copy of self

Public static methods and constants

	variant	**ask_existing_dir**	(string title, string dir)	Open a dialog to select a directory
	variant	**ask_open_file_name**	(string title, string dir,	Select one file for opening

			string filter)	
	variant	ask_open_file_names	(string title, string dir, string filter)	Select one or multiple files for opening
	variant	ask_save_file_name	(string title, string dir, string filter)	Select one file for writing
	variant	ask_save_file_name_with_fi	(string title, string dir, string filter)	Select one file for writing

Deprecated methods (protected, public, static, non-static and constructors)

	void	create		Use of this method is deprecated. Use _create instead
	void	destroy		Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?		Use of this method is deprecated. Use _destroyed? instead
[static]	StringValue	get_existing_dir	(string title, string dir)	Use of this method is deprecated
[static]	StringValue	get_open_file_name	(string title, string dir, string filter)	Use of this method is deprecated
[static]	StringListValue	get_open_file_names	(string title, string dir, string filter)	Use of this method is deprecated
[static]	StringValue	get_save_file_name	(string title, string dir, string filter)	Use of this method is deprecated
[const]	bool	is_const_object?		Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void _**create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void _**destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

ask_existing_dir

Signature: *[static]* variant **ask_existing_dir** (string title, string dir)

Description: Open a dialog to select a directory

title:	The title of the dialog
dir:	The directory selected initially
Returns:	The directory path selected or "nil" if "Cancel" was pressed

This method has been introduced in version 0.23. It is somewhat easier to use than the get_... equivalent.

ask_open_file_name

Signature: *[static]* variant **ask_open_file_name** (string title, string dir, string filter)

Description: Select one file for opening

title:	The title of the dialog
dir:	The directory selected initially
filter:	The filters available, for example "Images (*.png *.xpm *.jpg);;Text files (*.txt);;XML files (*.xml)"
Returns:	The path of the file selected or "nil" if "Cancel" was pressed

This method has been introduced in version 0.23. It is somewhat easier to use than the get_... equivalent.

ask_open_file_names

Signature: *[static]* variant **ask_open_file_names** (string title, string dir, string filter)

Description: Select one or multiple files for opening

title:	The title of the dialog
dir:	The directory selected initially
filter:	The filters available, for example "Images (*.png *.xpm *.jpg);;Text files (*.txt);;XML files (*.xml)"
Returns:	An array with the file paths selected or "nil" if "Cancel" was pressed

This method has been introduced in version 0.23. It is somewhat easier to use than the get_... equivalent.

ask_save_file_name

Signature: *[static]* variant **ask_save_file_name** (string title, string dir, string filter)

Description: Select one file for writing

title:	The title of the dialog
dir:	The directory selected initially
filter:	The filters available, for example "Images (*.png *.xpm *.jpg);;Text files (*.txt);;XML files (*.xml)"
Returns:	The path of the file chosen or "nil" if "Cancel" was pressed

This method has been introduced in version 0.23. It is somewhat easier to use than the get_... equivalent.

ask_save_file_name_with_fi

Signature: *[static]* variant **ask_save_file_name_with_filter** (string title, string dir, string filter)

Description: Select one file for writing

title:	The title of the dialog
dir:	The directory selected initially
filter:	The filters available, for example "Images (*.png *.xpm *.jpg);;Text files (*.txt);;XML files (*.xml)"
Returns:	"nil" if "Cancel" was pressed, otherwise a pair: The path of the file chosen and the index selected file type (-1 if no specific type was selected)

This method has been introduced in version 0.28.11.

assign

Signature: void **assign** (const FileDialog other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new FileDialog ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

get_existing_dir

Signature: *[static]* StringValue **get_existing_dir** (string title, string dir)

Description: Open a dialog to select a directory

title:	The title of the dialog
dir:	The directory selected initially
Returns:	A StringValue object that contains the directory path selected or with has_value? = false if "Cancel" was pressed

Use of this method is deprecated

Starting with version 0.23 this method is deprecated. Use ask_existing_dir instead.

get_open_file_name

Signature: *[static]* StringValue **get_open_file_name** (string title, string dir, string filter)

Description: Select one file for opening

title:	The title of the dialog
dir:	The directory selected initially
filter:	The filters available, for example "Images (*.png *.xpm *.jpg);;Text files (*.txt);;XML files (*.xml)"
Returns:	A StringValue object that contains the files selected or with has_value? = false if "Cancel" was pressed

Use of this method is deprecated

Starting with version 0.23 this method is deprecated. Use ask_open_file_name instead.

get_open_file_names

Signature: *[static]* StringListValue **get_open_file_names** (string title, string dir, string filter)

Description: Select one or multiple files for opening

title:	The title of the dialog
dir:	The directory selected initially
filter:	The filters available, for example "Images (*.png *.xpm *.jpg);;Text files (*.txt);;XML files (*.xml)"

Returns: A StringListValue object that contains the files selected or with has_value? = false if "Cancel" was pressed

Use of this method is deprecated

Starting with version 0.23 this method is deprecated. Use ask_open_file_names instead.

get_save_file_name

Signature: *[static]* StringValue **get_save_file_name** (string title, string dir, string filter)

Description: Select one file for writing

title: The title of the dialog

dir: The directory selected initially

filter: The filters available, for example "Images (*.png *.xpm *.jpg);;Text files (*.txt);;XML files (*.xml)"

Returns: A StringValue object that contains the files selected or with has_value? = false if "Cancel" was pressed

Use of this method is deprecated

Starting with version 0.23 this method is deprecated. Use ask_save_file_name instead.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new FileDialog ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

4.215. API reference - Class MessageBox

Notation used in Ruby API documentation

Module: lay

Description: Various methods to display message boxes

Class hierarchy: MessageBox » QMainWindow » QWidget » QObject

This class provides some basic message boxes. This functionality is provided through the static (class) methods warning, question and so on.

Here is some example:

```
# issue a warning and ask whether to continue:
v = RBA::MessageBox::warning("Dialog Title", "Something happened. Continue?", RBA::MessageBox::Yes +
 RBA::MessageBox::No)
if v == RBA::MessageBox::Yes
  ... continue ...
end
```

If you have enabled the Qt binding, you can use QMessageBox directly.

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const MessageE other)	Assigns another object to self
[const]	new MessageBox ptr	**dup**		Creates a copy of self

Public static methods and constants

int	**Abort**	A constant describing the 'Abort' button
int	**Cancel**	A constant describing the 'Cancel' button
int	**Ignore**	A constant describing the 'Ignore' button
int	**No**	A constant describing the 'No' button
int	**Ok**	A constant describing the 'Ok' button

int	**Retry**		A constant describing the 'Retry' button
int	**Yes**		A constant describing the 'Yes' button
int	**critical**	(string title, string text, int buttons)	Open a critical (error) message box
int	**info**	(string title, string text, int buttons)	Open a information message box
int	**question**	(string title, string text, int buttons)	Open a question message box
int	**warning**	(string title, string text, int buttons)	Open a warning message box

Deprecated methods (protected, public, static, non-static and constructors)

[static]	int	**b_abort**	Use of this method is deprecated. Use Abort instead
[static]	int	**b_cancel**	Use of this method is deprecated. Use Cancel instead
[static]	int	**b_ignore**	Use of this method is deprecated. Use Ignore instead
[static]	int	**b_no**	Use of this method is deprecated. Use No instead
[static]	int	**b_ok**	Use of this method is deprecated. Use Ok instead
[static]	int	**b_retry**	Use of this method is deprecated. Use Retry instead
[static]	int	**b_yes**	Use of this method is deprecated. Use Yes instead

Detailed description

Abort

Signature: *[static]* int **Abort**

Description: A constant describing the 'Abort' button

Python specific notes:
The object exposes a readable attribute 'Abort'. This is the getter.

Cancel

Signature: *[static]* int **Cancel**

Description: A constant describing the 'Cancel' button

Python specific notes:
The object exposes a readable attribute 'Cancel'. This is the getter.

Ignore

Signature: *[static]* int **Ignore**

Description: A constant describing the 'Ignore' button

Python specific notes:
The object exposes a readable attribute 'Ignore'. This is the getter.

No

Signature: *[static]* int **No**

Description: A constant describing the 'No' button

Python specific notes:
The object exposes a readable attribute 'No'. This is the getter.

Ok

Signature: *[static]* int **Ok**

Description: A constant describing the 'Ok' button

Python specific notes:
The object exposes a readable attribute 'Ok'. This is the getter.

Retry

Signature: *[static]* int **Retry**

Description: A constant describing the 'Retry' button

Python specific notes:
The object exposes a readable attribute 'Retry'. This is the getter.

Yes

Signature: *[static]* int **Yes**

Description: A constant describing the 'Yes' button

Python specific notes:
The object exposes a readable attribute 'Yes'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known

not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const MessageBox other)

Description: Assigns another object to self

b_abort

Signature: *[static]* int **b_abort**

Description: A constant describing the 'Abort' button

Use of this method is deprecated. Use Abort instead

Python specific notes:
The object exposes a readable attribute 'Abort'. This is the getter.

b_cancel

Signature: *[static]* int **b_cancel**

Description: A constant describing the 'Cancel' button

Use of this method is deprecated. Use Cancel instead

Python specific notes:
The object exposes a readable attribute 'Cancel'. This is the getter.

b_ignore

Signature: *[static]* int **b_ignore**

Description: A constant describing the 'Ignore' button

Use of this method is deprecated. Use Ignore instead

Python specific notes:
The object exposes a readable attribute 'Ignore'. This is the getter.

b_no

Signature: *[static]* int **b_no**

Description: A constant describing the 'No' button

Use of this method is deprecated. Use No instead

Python specific notes:
The object exposes a readable attribute 'No'. This is the getter.

b_ok

Signature: *[static]* int **b_ok**

Description: A constant describing the 'Ok' button

Use of this method is deprecated. Use Ok instead

Python specific notes:
The object exposes a readable attribute 'Ok'. This is the getter.

b_retry

Signature: *[static]* int **b_retry**

Description: A constant describing the 'Retry' button

Use of this method is deprecated. Use Retry instead

Python specific notes:
The object exposes a readable attribute 'Retry'. This is the getter.

b_yes

Signature: *[static]* int **b_yes**

Description: A constant describing the 'Yes' button

Use of this method is deprecated. Use Yes instead

Python specific notes:
The object exposes a readable attribute 'Yes'. This is the getter.

critical

Signature: *[static]* int **critical** (string title, string text, int buttons)

Description: Open a critical (error) message box

title:	The title of the window
text:	The text to show
buttons:	A combination (+) of button constants (Ok and so on) describing the buttons to show for the message box
Returns:	The button constant describing the button that was pressed

dup

Signature: *[const]* new MessageBox ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

info

Signature: *[static]* int **info** (string title, string text, int buttons)

Description: Open a information message box

title:	The title of the window
text:	The text to show
buttons:	A combination (+) of button constants (Ok and so on) describing the buttons to show for the message box
Returns:	The button constant describing the button that was pressed

question

Signature: *[static]* int **question** (string title, string text, int buttons)

Description: Open a question message box

title:	The title of the window
text:	The text to show
buttons:	A combination (+) of button constants (Ok and so on) describing the buttons to show for the message box
Returns:	The button constant describing the button that was pressed

warning

Signature: *[static]* int **warning** (string title, string text, int buttons)

Description: Open a warning message box

title:	The title of the window

text:	The text to show
buttons:	A combination (+) of button constants (Ok and so on) describing the buttons to show for the message box
Returns:	The button constant describing the button that was pressed

4.216. API reference - Class NetlistObjectPath

Notation used in Ruby API documentation

Module: lay

Description: An object describing the instantiation of a netlist object.

This class describes the instantiation of a net or a device or a circuit in terms of a root circuit and a subcircuit chain leading to the indicated object.

See net= or device= for the indicated object, path= for the subcircuit chain.

This class has been introduced in version 0.27.

Public constructors

new NetlistObjectPath ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const NetlistObjectPa other)	Assigns another object to self
[const]	Device ptr	**device**		Gets the device the path points to.
	void	**device=**	(Device ptr device)	Sets the device the path points to.
[const]	new NetlistObjectPath ptr	**dup**		Creates a copy of self
[const]	bool	**is_null?**		Returns a value indicating whether the path is an empty one.
[const]	Net ptr	**net**		Gets the net the path points to.
	void	**net=**	(Net ptr net)	Sets the net the path points to.
[const]	SubCircuit ptr[]	**path**		Gets the path.

	void	path=	(SubCircuit ptr[] path)	Sets the path.
[const]	Circuit ptr	root		Gets the root circuit of the path.
	void	root=	(Circuit ptr root)	Sets the root circuit of the path.

Deprecated methods (protected, public, static, non-static and constructors)

	void	create	Use of this method is deprecated. Use _create instead
	void	destroy	Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	is_const_object?	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void _**create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void _**destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool _**destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool _**is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void _**manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

	Usually it's not required to call this method. It has been introduced in version 0.24.
_unmanage	**Signature**: void **_unmanage** **Description**: Marks the object as no longer owned by the script side. Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.
assign	**Signature**: void **assign** (const NetlistObjectPath other) **Description**: Assigns another object to self
create	**Signature**: void **create** **Description**: Ensures the C++ object is created Use of this method is deprecated. Use _create instead Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
destroy	**Signature**: void **destroy** **Description**: Explicitly destroys the object Use of this method is deprecated. Use _destroy instead Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
destroyed?	**Signature**: *[const]* bool **destroyed?** **Description**: Returns a value indicating whether the object was already destroyed Use of this method is deprecated. Use _destroyed? instead This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
device	**Signature**: *[const]* Device ptr **device** **Description**: Gets the device the path points to. **Python specific notes:** The object exposes a readable attribute 'device'. This is the getter.
device=	**Signature**: void **device=** (Device ptr device) **Description**: Sets the device the path points to. If the path describes the location of a device, this member will indicate it. The other way to describe a final object is net=. If neither a device nor net is given, the path describes a circuit and how it is referenced from the root. **Python specific notes:** The object exposes a writable attribute 'device'. This is the setter.

dup

Signature: *[const]* new NetlistObjectPath ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_null?

Signature: *[const]* bool **is_null?**

Description: Returns a value indicating whether the path is an empty one.

net

Signature: *[const]* Net ptr **net**

Description: Gets the net the path points to.

Python specific notes:
The object exposes a readable attribute 'net'. This is the getter.

net=

Signature: void **net=** (Net ptr net)

Description: Sets the net the path points to.

If the path describes the location of a net, this member will indicate it. The other way to describe a final object is device=. If neither a device nor net is given, the path describes a circuit and how it is referenced from the root.

Python specific notes:
The object exposes a writable attribute 'net'. This is the setter.

new

Signature: *[static]* new NetlistObjectPath ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

path

Signature: *[const]* SubCircuit ptr[] **path**

Description: Gets the path.

Python specific notes:
The object exposes a readable attribute 'path'. This is the getter.

path=

Signature: void **path=** (SubCircuit ptr[] path)

Description: Sets the path.

The path is a list of subcircuits leading from the root to the final object. The final (net, device) object is located in the circuit called by the last subcircuit of the subcircuit chain. If the subcircuit list is empty, the final object is located inside the root object.

Python specific notes:
The object exposes a writable attribute 'path'. This is the setter.

root

Signature: *[const]* Circuit ptr **root**

Description: Gets the root circuit of the path.

Python specific notes:
The object exposes a readable attribute 'root'. This is the getter.

root=

Signature: void **root=** (Circuit ptr root)

Description: Sets the root circuit of the path.

The root circuit is the circuit from which the path starts.

Python specific notes:
The object exposes a writable attribute 'root'. This is the setter.

4.217. API reference - Class NetlistObjectsPath

Notation used in Ruby API documentation

Module: lay

Description: An object describing the instantiation of a single netlist object or a pair of those.

This class is basically a pair of netlist object paths (see NetlistObjectPath). When derived from a single netlist view, only the first path is valid and will point to the selected object (a net, a device or a circuit). The second path is null.

If the path is derived from a paired netlist view (a LVS report view), the first path corresponds to the object in the layout netlist, the second one to the object in the schematic netlist. If the selected object isn't a matched one, either the first or second path may be a null or a partial path without a final net or device object or a partial path.

This class has been introduced in version 0.27.

Public constructors

new NetlistObjectsPath ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const NetlistObj other)	Assigns another object to self
[const]	new NetlistObjectsPath ptr	**dup**		Creates a copy of self
[const]	NetlistObjectPath	**first**		Gets the first object's path.
[const]	NetlistObjectPath	**second**		Gets the second object's path.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead

[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const NetlistObjectsPath other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new NetlistObjectsPath ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

first

Signature: *[const]* NetlistObjectPath **first**

Description: Gets the first object's path.

In cases of paired netlists (LVS database), the first path points to the layout netlist object. For the single netlist, the first path is the only path supplied.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new NetlistObjectsPath ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

second

Signature: *[const]* NetlistObjectPath **second**

Description: Gets the second object's path.

In cases of paired netlists (LVS database), the first path points to the schematic netlist object. For the single netlist, the second path is always a null path.

4.218. API reference - Class NetlistBrowserDialog

Notation used in Ruby API documentation

Module: lay

Description: Represents the netlist browser dialog.

This dialog is a part of the LayoutView class and can be obtained through LayoutView#netlist_browser. This interface allows to interact with the browser - mainly to get information about state changes.

This class has been introduced in version 0.27.

Public constructors

new NetlistBrowserDialog ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	NetlistObjectsPath	**current_path**		Gets the path of the current object as a path pair (combines layout and schematic object paths in case of a LVS database view).
	NetlistObjectPath	**current_path_first**		Gets the path of the current object on the first (layout in case of LVS database) side.
	NetlistObjectPath	**current_path_second**		Gets the path of the current object on the second (schematic in case of LVS database) side.
	LayoutToNetlist ptr	**db**		Gets the database the browser is connected to.
[signal]	void	**on_current_db_changed**		This event is triggered when the current database is changed.
[signal]	void	**on_probe**	(NetlistObjectPath first_path, NetlistObjectPath second_path)	This event is triggered when a net is probed.
[signal]	void	**on_selection_changed**		This event is triggered when the selection changed.
[const]	NetlistObjectsPath[]	**selected_paths**		Gets the nets currently selected objects (paths) in the netlist database browser.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method

will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

current_path

Signature: *[const]* NetlistObjectsPath **current_path**

Description: Gets the path of the current object as a path pair (combines layout and schematic object paths in case of a LVS database view).

current_path_first

Signature: NetlistObjectPath **current_path_first**

Description: Gets the path of the current object on the first (layout in case of LVS database) side.

current_path_second

Signature: NetlistObjectPath **current_path_second**

Description: Gets the path of the current object on the second (schematic in case of LVS database) side.

db

Signature: LayoutToNetlist ptr **db**

Description: Gets the database the browser is connected to.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new NetlistBrowserDialog ptr **new**

Description: Creates a new object of this class

	Python specific notes: This method is the default initializer of the object.
on_current_db_changed	**Signature**: *[signal]* void **on_current_db_changed** **Description**: This event is triggered when the current database is changed. The current database can be obtained with db. **Python specific notes:** The object exposes a readable attribute 'on_current_db_changed'. This is the getter. The object exposes a writable attribute 'on_current_db_changed'. This is the setter.
on_probe	**Signature**: *[signal]* void **on_probe** (NetlistObjectPath first_path, NetlistObjectPath second_path) **Description**: This event is triggered when a net is probed. The first path will indicate the location of the probed net in terms of two paths: one describing the instantiation of the net in layout space and one in schematic space. Both objects are NetlistObjectPath objects which hold the root circuit, the chain of subcircuits leading to the circuit containing the net and the net itself. **Python specific notes:** The object exposes a readable attribute 'on_probe'. This is the getter. The object exposes a writable attribute 'on_probe'. This is the setter.
on_selection_changed	**Signature**: *[signal]* void **on_selection_changed** **Description**: This event is triggered when the selection changed. The selection can be obtained with current_path_first, current_path_second, selected_nets, selected_devices, selected_subcircuits and selected_circuits. **Python specific notes:** The object exposes a readable attribute 'on_selection_changed'. This is the getter. The object exposes a writable attribute 'on_selection_changed'. This is the setter.
selected_paths	**Signature**: *[const]* NetlistObjectsPath[] **selected_paths** **Description**: Gets the nets currently selected objects (paths) in the netlist database browser. The result is an array of path pairs. See NetlistObjectsPath for details about these pairs.

4.219. API reference - Class LayoutViewWidget

Notation used in Ruby API documentation

Module: lay

Description:

Class hierarchy: LayoutViewWidget » QFrame » QWidget » QObject

This object produces a widget which embeds a LayoutView. This widget can be used inside Qt widget hierarchies. To access the LayoutView object within, use view.

This class has been introduced in version 0.28.

Public constructors

new LayoutViewWidget ptr	**new**	(QWidget ptr parent, bool editable = false, Manager ptr manager = nil, unsigned int options = 0)	Creates a standalone view widget

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference
	void	**_manage**	Marks the object as managed by the script side.
	void	**_unmanage**	Marks the object as no longer owned by the script side.
	QWidget ptr	**bookmarks_frame**	Gets the bookmarks side widget
	QWidget ptr	**hierarchy_control_frame**	Gets the cell view (hierarchy view) side widget
	QWidget ptr	**layer_control_frame**	Gets the layer control side widget
	QWidget ptr	**layer_toolbox_frame**	Gets the layer toolbox side widget
	QWidget ptr	**libraries_frame**	Gets the library view side widget
	LayoutView ptr	**view**	Gets the embedded view object.

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

bookmarks_frame

Signature: QWidget ptr **bookmarks_frame**

Description: Gets the bookmarks side widget

For details about side widgets see layer_control_frame.

This method has been introduced in version 0.27

hierarchy_control_frame

Signature: QWidget ptr **hierarchy_control_frame**

Description: Gets the cell view (hierarchy view) side widget

For details about side widgets see layer_control_frame.

This method has been introduced in version 0.27

layer_control_frame

Signature: QWidget ptr **layer_control_frame**

Description: Gets the layer control side widget

A 'side widget' is a widget attached to the view. It does not have a parent, so you can embed it into a different context. Please note that with embedding through 'setParent' it will be destroyed when your parent widget gets destroyed. It will be lost then to the view.

The side widget can be configured through the views configuration interface.

This method has been introduced in version 0.27

layer_toolbox_frame

Signature: QWidget ptr **layer_toolbox_frame**

Description: Gets the layer toolbox side widget

A 'side widget' is a widget attached to the view. It does not have a parent, so you can embed it into a different context. Please note that with embedding through 'setParent' it will be destroyed when your parent widget gets destroyed. It will be lost then to the view.

The side widget can be configured through the views configuration interface.

This method has been introduced in version 0.28

libraries_frame

Signature: QWidget ptr **libraries_frame**

Description: Gets the library view side widget

For details about side widgets see layer_control_frame.

This method has been introduced in version 0.27

new

Signature: *[static]* new LayoutViewWidget ptr **new** (QWidget ptr parent, bool editable = false, Manager ptr manager = nil, unsigned int options = 0)

Description: Creates a standalone view widget

parent:	The parent widget in which to embed the view
editable:	True to make the view editable
manager:	The Manager object to enable undo/redo
options:	A combination of the values in the LV_... constants from LayoutViewBase

This constructor has been introduced in version 0.25. It has been enhanced with the arguments in version 0.27.

Python specific notes:
This method is the default initializer of the object.

view

Signature: LayoutView ptr **view**

Description: Gets the embedded view object.

4.220. API reference - Class LayoutView

Notation used in Ruby API documentation

Module: lay

Description: The view object presenting one or more layout objects

Class hierarchy: LayoutView

Sub-classes: SelectionMode

The visual part of the view is the tab panel in the main window. The non-visual part are the redraw thread, the layout handles, cell lists, layer view lists etc. This object controls these aspects of the view and controls the appearance of the data.

Public constructors

new LayoutView ptr	**new**	(bool editable = false, Manager ptr manager = nil, unsigned int options = 0)	Creates a standalone view

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	CellView	**active_cellview**		Gets the active cellview (shown in hierarchy browser)
[const]	int	**active_cellview_index**		Gets the index of the active cellview (shown in hierarchy browser)
	void	**active_setview_index=**	(int index)	Makes the cellview with the given index the active one (shown in hierarchy browser)
	unsigned int	**add_l2ndb**	(LayoutToNetlist ptr db)	Adds the given netlist database to the view
	unsigned int	**add_line_style**	(string name, unsigned int data, unsigned int bits)	Adds a custom line style
	unsigned int	**add_line_style**	(string name, string string)	Adds a custom line style from a string

	unsigned int	**add_lvsdb**	(LayoutVsSchematic ptr db)	Adds the given database to the view
	void	**add_missing_layers**		Adds new layers to layer list
	unsigned int	**add_rdb**	(ReportDatabase ptr db)	Adds the given report database to the view
	unsigned int	**add_stipple**	(string name, unsigned int[] data, unsigned int bits)	Adds a stipple pattern
	unsigned int	**add_stipple**	(string name, string string)	Adds a stipple pattern given by a string
	Annotation	**annotation**	(int id)	Gets the annotation given by an ID
	variant[][]	**annotation_templates**		Gets a list of Annotation objects representing the annotation templates.
	InstElement	**ascend**	(int index)	Ascends upwards in the hierarchy.
[const]	LayerPropertiesIterat	**begin_layers**		Begin iterator for the layers
[const]	LayerPropertiesIterator	**begin_layers**	(unsigned int index)	Begin iterator for the layers
	void	**bookmark_view**	(string name)	Bookmarks the current view under the given name
[const]	DBox	**box**		Returns the displayed box in micron space
	void	**call_menu**	(string symbol)	Calls the menu item with the provided symbol.
	void	**cancel**		Cancels all edit operations
	CellView	**cellview**	(unsigned int cv_index)	Gets the cellview object for a given index
[const]	unsigned int	**cellviews**		Gets the number of cellviews
	void	**clear_annotations**		Clears all annotations on this view
	void	**clear_config**		Clears the local configuration parameters
	void	**clear_images**		Clear all images on this view
	void	**clear_layers**		Clears all layers
	void	**clear_layers**	(unsigned int index)	Clears all layers for the given layer properties list
	void	**clear_line_styles**		Removes all custom line styles
[const]	void	**clear_object_selection**		Clears the selection of geometrical objects (shapes or cell instances)

	void	clear_selection		Clears the selection of all objects (shapes, annotations, images ...)
	void	clear_stipples		Removes all custom line styles
	void	clear_transactions		Clears all transactions
	void	clear_transient_selection		Clears the transient selection (mouse-over hightlights) of all objects (shapes, annotations, images ...)
	void	close		Closes the view
	void	commit		Ends a transaction
	void	commit_config		Commits the configuration settings
	unsigned int	create_l2ndb	(string name)	Creates a new netlist database and returns the index of the new database
	unsigned int	create_layout	(bool add_cellview)	Creates a new, empty layout
	unsigned int	create_layout	(string tech, bool add_cellview)	Create a new, empty layout and associate it with the given technology
	unsigned int	create_layout	(string tech, bool add_cellview, bool init_layers)	Create a new, empty layout and associate it with the given technology
	unsigned int	create_lvsdb	(string name)	Creates a new netlist database and returns the index of the new database
	Annotation	create_measure_ruler	(const DPoint point, int ac = Annotation#AngleAny)	Createas an auto-measure ruler at the given point.
	unsigned int	create_rdb	(string name)	Creates a new report database and returns the index of the new database
[const]	LayerPropertiesIterator	current_layer		Gets the current layer view
	void	current_layer=	(const LayerPropertiesIterator iter)	Sets the current layer view
[const]	unsigned int	current_layer_list		Gets the index of the currently selected layer properties tab
	void	current_layer_list=	(unsigned int index)	Sets the index of the currently selected layer properties tab
	void	delete_layer	(LayerPropertiesIterator iter)	Deletes the layer properties node specified by the iterator
	void	delete_layer	(unsigned int index, LayerPropertiesIterator iter)	Deletes the layer properties node specified by the iterator
	void	delete_layer_list	(unsigned int index)	Deletes the given properties list

	void	**delete_layers**	(LayerPropertiesIterator iterators)	Deletes the layer properties nodes specified by the iterator
	void	**delete_layers**	(unsigned int index, LayerPropertiesIterator[] iterators)	Deletes the layer properties nodes specified by the iterator
	void	**descend**	(InstElement[] path, int index)	Descends further into the hierarchy.
[iter]	Annotation	**each_annotation**		Iterates over all annotations attached to this view
[const,iter]	Annotation	**each_annotation_selecte**		Iterate over each selected annotation objects, yielding a Annotation object for each of them
[iter]	Image	**each_image**		Iterate over all images attached to this view
[const,iter]	Image	**each_image_selected**		Iterate over each selected image object, yielding a Image object for each of them
[iter]	LayerPropertiesNodeRef	**each_layer**		Hierarchically iterates over the layers in the first layer list
[iter]	LayerPropertiesNode	**each_layer**	(unsigned int layer_list)	Hierarchically iterates over the layers in the given layer list
[const,iter]	ObjectInstPath	**each_object_selected**		Iterates over each selected geometrical object, yielding a ObjectInstPath object for each of them
[const,iter]	ObjectInstPath	**each_object_selected_tra**		Iterates over each geometrical objects in the transient selection, yielding a ObjectInstPath object for each of them
	void	**enable_edits**	(bool enable)	Enables or disables edits
[const]	LayerPropertiesIterat	**end_layers**		End iterator for the layers
[const]	LayerPropertiesIterator	**end_layers**	(unsigned int index)	End iterator for the layers
	void	**erase_annotation**	(int id)	Erases the annotation given by the id
	void	**erase_cellview**	(unsigned int index)	Erases the cellview with the given index
	void	**erase_image**	(unsigned long id)	Erase the given image
	void	**expand_layer_properties**		Expands the layer properties for all tabs
	void	**expand_layer_properties**	(unsigned int index)	Expands the layer properties for the given tab
[const]	string	**get_config**	(string name)	Gets the value of a local configuration parameter
	string[]	**get_config_names**		Gets the configuration parameter names
	QImage	**get_image**	(unsigned int width,	Gets the layout image as a QImage

			unsigned int height)	
	QImage	**get_image_with_options**	(unsigned int width, unsigned int height, int linewidth = 0, int oversampling = 0, double resolution = 0, const DBox target = current, bool monochrome = false)	Gets the layout image as a QImage (with options)
	string	**get_line_style**	(unsigned int index)	Gets the line style string for the style with the given index
	PixelBuffer	**get_pixels**	(unsigned int width, unsigned int height)	Gets the layout image as a PixelBuffer
	PixelBuffer	**get_pixels_with_options**	(unsigned int width, unsigned int height, int linewidth = 0, int oversampling = 0, double resolution = 0, const DBox target = current)	Gets the layout image as a PixelBuffer (with options)
	BitmapBuffer	**get_pixels_with_options_**	(unsigned int width, unsigned int height, int linewidth = 0, const DBox target = current)	Gets the layout image as a PixelBuffer (with options)
	QImage	**get_screenshot**		Gets a screenshot as a QImage
	PixelBuffer	**get_screenshot_pixels**		Gets a screenshot as a PixelBuffer
	string	**get_stipple**	(unsigned int index)	Gets the stipple pattern string for the pattern with the given index
[const]	bool	**has_annotation_selectio**		Returns true, if annotations (rulers) are selected in this view
[const]	bool	**has_image_selection?**		Returns true, if images are selected in this view
[const]	bool	**has_object_selection?**		Returns true, if geometrical objects (shapes or cell instances) are selected in this view
	bool	**has_selection?**		Indicates whether any objects are selected
[const]	bool	**has_transient_object_sel**		Returns true, if geometrical objects (shapes or cell instances) are selected in this view in the transient selection
	void	**hide_cell**	(unsigned int cell_index, int cv_index)	Hides the given cell for the given cellview

	PixelBuffer	**icon_for_layer**	(const LayerPropertiesIterator iter, unsigned int w, unsigned int h, double dpr, unsigned int di_off = 0, bool no_state = false)	Creates an icon pixmap for the given layer.
	Image	**image**	(unsigned long id)	Gets the image given by an ID
[const]	void	**init_layer_properties**	(LayerProperties props)	Fills the layer properties for a new layer
	void	**insert_annotation**	(Annotation ptr obj)	Inserts an annotation object into the given view
	void	**insert_image**	(Image obj)	Insert an image object into the given view
	LayerPropertiesNodeRef	**insert_layer**	(const LayerPropertiesIterator iter, const LayerProperties node = LayerProperties())	Inserts the given layer properties node into the list before the given position
	LayerPropertiesNode	**insert_layer**	(unsigned int index, const LayerPropertiesIterator iter, const LayerProperties node = LayerProperties())	Inserts the given layer properties node into the list before the given position
	void	**insert_layer_list**	(unsigned int index)	Inserts a new layer properties list at the given index
[const]	bool	**is_cell_hidden?**	(unsigned int cell_index, int cv_index)	Returns true, if the cell is hidden
	bool	**is_dirty?**		Gets a flag indicating whether one of the layouts displayed needs saving
[const]	bool	**is_editable?**		Returns true if the view is in editable mode
	bool	**is_transacting?**		Indicates if a transaction is ongoing
	LayoutToNetlist ptr	**l2ndb**	(int index)	Gets the netlist database with the given index
	void	**load_layer_props**	(string fn)	Loads the layer properties
	void	**load_layer_props**	(string fn, bool add_default)	Loads the layer properties with options
	void	**load_layer_props**	(string fn, int cv_index,	Loads the layer properties with options

			bool add_default)	
	unsigned int	**load_layout**	(string filename, const LoadLayoutOptions options, string technology, bool add_cellview = true)	Loads a (new) file into the layout view with the given technology
	unsigned int	**load_layout**	(string filename, const LoadLayoutOptions options, bool add_cellview = true)	Loads a (new) file into the layout view
	unsigned int	**load_layout**	(string filename, string technology, bool add_cellview = true)	Loads a (new) file into the layout view with the given technology
	unsigned int	**load_layout**	(string filename, bool add_cellview = true)	Loads a (new) file into the layout view
	LayoutVsSchematic ptr	**lvsdb**	(unsigned int index)	Gets the netlist database with the given index
	void	**max_hier**		Selects all hierarchy levels available
[const]	int	**max_hier_levels**		Returns the maximum hierarchy level up to which to display geometries
	void	**max_hier_levels=**	(int level)	Sets the maximum hierarchy level up to which to display geometries
	AbstractMenu ptr	**menu**		Gets the AbstractMenu associated with this view.
[const]	int	**min_hier_levels**		Returns the minimum hierarchy level at which to display geometries
	void	**min_hier_levels=**	(int level)	Sets the minimum hierarchy level at which to display geometries
[const]	string	**mode_name**		Gets the name of the current mode.
[const]	string[]	**mode_names**		Gets the names of the available modes.
	NetlistBrowserDialog ptr	**netlist_browser**		Gets the netlist browser object for the given layout view
[const]	unsigned int	**num_l2ndbs**		Gets the number of netlist databases loaded into this view
[const]	unsigned int	**num_layer_lists**		Gets the number of layer properties tabs present

[const]	unsigned int	**num_rdbs**		Gets the number of report databases loaded into this view
[const]	ObjectInstPath[]	**object_selection**		Returns a list of selected objects
[const]	void	**object_selection=**	(ObjectInstPath[] sel)	Sets the list of selected objects
[signal]	void	**on_active_cellview_changed**		An event indicating that the active cellview has changed
[signal]	void	**on_annotation_changed**	(int id)	A event indicating that an annotation has been modified
[signal]	void	**on_annotation_selection_changed**		A event indicating that the annotation selection has changed
[signal]	void	**on_annotations_changed**		A event indicating that annotations have been added or removed
[signal]	void	**on_apply_technology**	(int cellview_index)	An event indicating that a cellview has requested a new technology
[signal]	void	**on_cell_visibility_change**		An event indicating that the visibility of one or more cells has changed
[signal]	void	**on_cellview_changed**	(int cellview_index)	An event indicating that a cellview has changed
[signal]	void	**on_cellviews_changed**		An event indicating that the cellview collection has changed
[signal]	void	**on_close**		A event indicating that the view is about to close
[signal]	void	**on_current_layer_list_ch**	(int index)	An event indicating the current layer list (the selected tab) has changed
[signal]	void	**on_file_open**		An event indicating that a file was opened
[signal]	void	**on_hide**		A event indicating that the view is going to become invisible
[signal]	void	**on_image_changed**	(int id)	A event indicating that an image has been modified
[signal]	void	**on_image_selection_cha**		A event indicating that the image selection has changed
[signal]	void	**on_images_changed**		A event indicating that images have been added or removed
[signal]	void	**on_l2ndb_list_changed**		An event that is triggered the list of netlist databases is changed
[signal]	void	**on_layer_list_changed**	(int flags)	An event indicating that the layer list has changed
[signal]	void	**on_layer_list_deleted**	(int index)	An event indicating that a layer list (a tab) has been removed

[signal]	void	**on_layer_list_inserted**	(int index)	An event indicating that a layer list (a tab) has been inserted
[signal]	void	**on_rdb_list_changed**		An event that is triggered the list of report databases is changed
[signal]	void	**on_selection_changed**		An event that is triggered if the selection is changed
[signal]	void	**on_show**		A event indicating that the view is going to become visible
[signal]	void	**on_transient_selection_changed**		An event that is triggered if the transient selection is changed
[signal]	void	**on_viewport_changed**		An event indicating that the viewport (the visible rectangle) has changed
	D25View ptr	**open_d25_view**		Opens the 2.5d view window and returns a reference to the D25View object.
	void	**pan_center**	(const DPoint p)	Pans to the given point
	void	**pan_down**		Pans down
	void	**pan_left**		Pans to the left
	void	**pan_right**		Pans to the right
	void	**pan_up**		Pans upward
	ReportDatabase ptr	**rdb**	(int index)	Gets the report database with the given index
	void	**register_annotation_tem**	(const Annotation annotation, string title, int mode = RulerModeNormal)	Registers the given annotation as a template for this particular view
	void	**reload_layout**	(unsigned int cv)	Reloads the given cellview
	void	**remove_l2ndb**	(unsigned int index)	Removes a netlist database with the given index
	void	**remove_line_style**	(unsigned int index)	Removes the line style with the given index
	void	**remove_rdb**	(unsigned int index)	Removes a report database with the given index
	void	**remove_stipple**	(unsigned int index)	Removes the stipple pattern with the given index
	void	**remove_unused_layers**		Removes unused layers from layer list
	void	**rename_cellview**	(string name, int index)	Renames the cellview with the given index

void	rename_layer_list	(unsigned int index, string name)	Sets the title of the given layer properties tab
void	replace_annotation	(int id, const Annotation obj)	Replaces the annotation given by the id with the new one
void	replace_image	(unsigned long id, Image new_obj)	Replace an image object with the new image
unsigned int	replace_l2ndb	(unsigned int db_index, LayoutToNetlist ptr db)	Replaces the netlist database with the given index
void	replace_layer_node	(const LayerPropertiesIterator iter, const LayerProperties node)	Replaces the layer node at the position given by "iter" with a new one
void	replace_layer_node	(unsigned int index, const LayerPropertiesIterator iter, const LayerProperties node)	Replaces the layer node at the position given by "iter" with a new one
unsigned int	replace_lvsdb	(unsigned int db_index, LayoutVsSchematic ptr db)	Replaces the database with the given index
unsigned int	replace_rdb	(unsigned int db_index, ReportDatabase ptr db)	Replaces the report database with the given index
void	reset_title		Resets the title to the standard title
void	resize	(unsigned int w, unsigned int h)	Resizes the layout view to the given dimension
void	save_as	(unsigned int index, string filename, const SaveLayoutOptions options)	Saves a layout to the given stream file
void	save_image	(string filename, unsigned int width, unsigned int height)	Saves the layout as an image to the given file
void	save_image_with_option	(string filename, unsigned int width, unsigned int height, int linewidth = 0, int oversampling = 0, double resolution = 0,	Saves the layout as an image to the given file (with options)

			const DBox target = current, bool monochrome = false)	
	void	**save_layer_props**	(string fn)	Saves the layer properties
	void	**save_screenshot**	(string filename)	Saves a screenshot to the given file
	void	**select_all**		Selects all objects from the view
	void	**select_from**	(const DPoint point, LayoutView::SelectionM mode = Replace)	Selects the objects from a given point
	void	**select_from**	(const DBox box, LayoutView::SelectionMode mode = Replace)	Selects the objects from a given box
[const]	void	**select_object**	(const ObjectInstPath obj)	Adds the given selection to the list of selected objects
[const]	unsigned int[][]	**selected_cells_paths**	(int cv_index)	Gets the paths of the selected cells
[const]	LayerPropertiesIterat	**selected_layers**		Gets the selected layers
	DBox	**selection_bbox**		Returns the bounding box of the current selection
	unsigned long	**selection_size**		Returns the number of selected objects
	void	**send_enter_event**		Sends a mouse window leave event
	void	**send_key_press_event**	(unsigned int key, unsigned int buttons)	Sends a key press event
	void	**send_leave_event**		Sends a mouse window leave event
	void	**send_mouse_double_clic**	(const DPoint pt, unsigned int buttons)	Sends a mouse button double-click event
	void	**send_mouse_move_event**	(const DPoint pt, unsigned int buttons)	Sends a mouse move event
	void	**send_mouse_press_ever**	(const DPoint pt, unsigned int buttons)	Sends a mouse button press event
	void	**send_mouse_release_event**	(const DPoint pt, unsigned int buttons)	Sends a mouse button release event
	void	**send_wheel_event**	(int delta, bool horizontal, const DPoint pt, unsigned int buttons)	Sends a mouse wheel event
	void	**set_config**	(string name, string value)	Sets a local configuration parameter with the given name to the given value

	void	**set_layer_properties**	(const LayerPropertiesIterator iter, const LayerProperties props)	Sets the layer properties of the layer pointed to by the iterator
	void	**set_layer_properties**	(unsigned int index, const LayerPropertiesIterator iter, const LayerProperties props)	Sets the layer properties of the layer pointed to by the iterator
	void	**show_all_cells**		Makes all cells shown (cancel effects of hide_cell)
	void	**show_all_cells**	(int cv_index)	Makes all cells shown (cancel effects of hide_cell) for the specified cell view
	void	**show_cell**	(unsigned int cell_index, int cv_index)	Shows the given cell for the given cellview (cancel effect of hide_cell)
	void	**show_image**	(unsigned long id, bool visible)	Shows or hides the given image
	void	**show_l2ndb**	(int l2ndb_index, int cv_index)	Shows a netlist database in the marker browser on a certain layout
	unsigned int	**show_layout**	(Layout ptr layout, bool add_cellview)	Shows an existing layout in the view
	unsigned int	**show_layout**	(Layout ptr layout, string tech, bool add_cellview)	Shows an existing layout in the view
	unsigned int	**show_layout**	(Layout ptr layout, string tech, bool add_cellview, bool init_layers)	Shows an existing layout in the view
	void	**show_lvsdb**	(int lvsdb_index, int cv_index)	Shows a netlist database in the marker browser on a certain layout
	void	**show_rdb**	(int rdb_index, int cv_index)	Shows a report database in the marker browser on a certain layout
	void	**stop**		Stops redraw thread and close any browsers
	void	**stop_redraw**		Stops the redraw thread
	void	**switch_mode**	(string mode)	Switches the mode.
[const]	string	**title**		Returns the view's title string
	void	**title=**	(string title)	Sets the title of the view

	void	**transaction**	(string description)	Begins a transaction
	void	**transient_to_selection**		Turns the transient selection into the actual selection
	void	**unregister_annotation_templates**	(string category)	Unregisters the template or templates with the given category string on this particular view
[const]	void	**unselect_object**	(const ObjectInstPath obj)	Removes the given selection from the list of selected objects
	void	**update_content**		Updates the layout view to the current state
[const]	int	**viewport_height**		Return the viewport height in pixels
[const]	DCplxTrans	**viewport_trans**		Returns the transformation that converts micron coordinates to pixels
[const]	int	**viewport_width**		Returns the viewport width in pixels
	QWidget ptr	**widget**		Gets the QWidget object of the view
	void	**zoom_box**	(const DBox box)	Sets the viewport to the given box
	void	**zoom_fit**		Fits the contents of the current view into the window
	void	**zoom_fit_sel**		Fits the contents of the current selection into the window
	void	**zoom_in**		Zooms in somewhat
	void	**zoom_out**		Zooms out somewhat

Public static methods and constants

[static,const]	LayoutView::SelectionMod	**Add**	Adds to any existing selection
[static,const]	LayoutView::SelectionMode	**Invert**	Adds to any existing selection, if it's not there yet or removes it from the selection if it's already selected
[static,const]	unsigned int	**LV_Naked**	With this option, no separate views will be provided
[static,const]	unsigned int	**LV_NoBookmarksView**	With this option, no bookmarks view will be provided (see bookmarks_frame)
[static,const]	unsigned int	**LV_NoEditorOptionsP**	With this option, no editor options panel will be provided (see editor_options_frame)
[static,const]	unsigned int	**LV_NoGrid**	With this option, the grid background is not shown
[static,const]	unsigned int	**LV_NoHierarchyPanel**	With this option, no cell hierarchy view will be provided (see hierarchy_control_frame)

[static,const]	unsigned int	**LV_NoLayers**	With this option, no layers view will be provided (see layer_control_frame)
[static,const]	unsigned int	**LV_NoLibrariesView**	With this option, no library view will be provided (see libraries_frame)
[static,const]	unsigned int	**LV_NoMove**	With this option, move operations are not supported
[static,const]	unsigned int	**LV_NoPlugins**	With this option, all plugins are disabled
[static,const]	unsigned int	**LV_NoPropertiesPopup**	This option disables the properties popup on double click
[static,const]	unsigned int	**LV_NoSelection**	With this option, objects cannot be selected
[static,const]	unsigned int	**LV_NoServices**	This option disables all services except the ones for pure viewing
[static,const]	unsigned int	**LV_NoTracker**	With this option, mouse position tracking is not supported
[static,const]	unsigned int	**LV_NoZoom**	With this option, zooming is disabled
[static,const]	LayoutView::SelectionMod	**Replace**	Replaces the existing selection
[static,const]	LayoutView::SelectionMode	**Reset**	Removes from any existing selection
	LayoutView ptr	**current**	Returns the current view
	string[]	**menu_symbols**	Gets all available menu symbols (see call_menu).

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**		Use of this method is deprecated. Use _create instead
	void	**destroy**		Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**		Use of this method is deprecated. Use _destroyed? instead
[const]	unsigned int[]	**get_current_cell_path**	(int cv_index)	Use of this method is deprecated
[const]	bool	**is_const_object?**		Use of this method is deprecated. Use _is_const_object? instead
	void	**save_as**	(unsigned int index, string filename, bool gzip, const SaveLayoutOptions options)	Use of this method is deprecated
	void	**select_cell**	(unsigned int cell_index, int cv_index)	Use of this method is deprecated

void	select_cell_path	(unsigned int[] cell_index, int cv_index)	Use of this method is deprecated
void	set_active_cellview_inde:	(int index)	Use of this method is deprecated. Use active_setview_index= instead
void	set_current_cell_path	(int cv_index, unsigned int[] cell_path)	Use of this method is deprecated
void	set_current_layer_list	(unsigned int index)	Use of this method is deprecated. Use current_layer_list= instead
void	set_title	(string title)	Use of this method is deprecated. Use title= instead

Detailed description

Add

Signature: *[static,const]* LayoutView::SelectionMode **Add**

Description: Adds to any existing selection

Python specific notes:
The object exposes a readable attribute 'Add'. This is the getter.

Invert

Signature: *[static,const]* LayoutView::SelectionMode **Invert**

Description: Adds to any existing selection, if it's not there yet or removes it from the selection if it's already selected

Python specific notes:
The object exposes a readable attribute 'Invert'. This is the getter.

LV_Naked

Signature: *[static,const]* unsigned int **LV_Naked**

Description: With this option, no separate views will be provided

Use this value with the constructor's 'options' argument. This option is basically equivalent to using LV_NoLayers+LV_NoHierarchyPanel+LV_NoLibrariesView+LV_NoBookmarksView

This constant has been introduced in version 0.27.

Python specific notes:
The object exposes a readable attribute 'LV_Naked'. This is the getter.

LV_NoBookmarksView

Signature: *[static,const]* unsigned int **LV_NoBookmarksView**

Description: With this option, no bookmarks view will be provided (see bookmarks_frame)

Use this value with the constructor's 'options' argument.

This constant has been introduced in version 0.27.

Python specific notes:
The object exposes a readable attribute 'LV_NoBookmarksView'. This is the getter.

LV_NoEditorOptionsPanel

Signature: *[static,const]* unsigned int **LV_NoEditorOptionsPanel**

Description: With this option, no editor options panel will be provided (see editor_options_frame)

Use this value with the constructor's 'options' argument.

This constant has been introduced in version 0.27.

Python specific notes:

	The object exposes a readable attribute 'LV_NoEditorOptionsPanel'. This is the getter.
LV_NoGrid	**Signature**: *[static,const]* unsigned int **LV_NoGrid** **Description**: With this option, the grid background is not shown Use this value with the constructor's 'options' argument. This constant has been introduced in version 0.27. **Python specific notes:** The object exposes a readable attribute 'LV_NoGrid'. This is the getter.
LV_NoHierarchyPanel	**Signature**: *[static,const]* unsigned int **LV_NoHierarchyPanel** **Description**: With this option, no cell hierarchy view will be provided (see hierarchy_control_frame) Use this value with the constructor's 'options' argument. This constant has been introduced in version 0.27. **Python specific notes:** The object exposes a readable attribute 'LV_NoHierarchyPanel'. This is the getter.
LV_NoLayers	**Signature**: *[static,const]* unsigned int **LV_NoLayers** **Description**: With this option, no layers view will be provided (see layer_control_frame) Use this value with the constructor's 'options' argument. This constant has been introduced in version 0.27. **Python specific notes:** The object exposes a readable attribute 'LV_NoLayers'. This is the getter.
LV_NoLibrariesView	**Signature**: *[static,const]* unsigned int **LV_NoLibrariesView** **Description**: With this option, no library view will be provided (see libraries_frame) Use this value with the constructor's 'options' argument. This constant has been introduced in version 0.27. **Python specific notes:** The object exposes a readable attribute 'LV_NoLibrariesView'. This is the getter.
LV_NoMove	**Signature**: *[static,const]* unsigned int **LV_NoMove** **Description**: With this option, move operations are not supported Use this value with the constructor's 'options' argument. This constant has been introduced in version 0.27. **Python specific notes:** The object exposes a readable attribute 'LV_NoMove'. This is the getter.
LV_NoPlugins	**Signature**: *[static,const]* unsigned int **LV_NoPlugins** **Description**: With this option, all plugins are disabled Use this value with the constructor's 'options' argument. This constant has been introduced in version 0.27. **Python specific notes:** The object exposes a readable attribute 'LV_NoPlugins'. This is the getter.

LV_NoPropertiesPopup

Signature: *[static,const]* unsigned int **LV_NoPropertiesPopup**

Description: This option disables the properties popup on double click

Use this value with the constructor's 'options' argument.

This constant has been introduced in version 0.28.

Python specific notes:
The object exposes a readable attribute 'LV_NoPropertiesPopup'. This is the getter.

LV_NoSelection

Signature: *[static,const]* unsigned int **LV_NoSelection**

Description: With this option, objects cannot be selected

Use this value with the constructor's 'options' argument.

This constant has been introduced in version 0.27.

Python specific notes:
The object exposes a readable attribute 'LV_NoSelection'. This is the getter.

LV_NoServices

Signature: *[static,const]* unsigned int **LV_NoServices**

Description: This option disables all services except the ones for pure viewing

Use this value with the constructor's 'options' argument. With this option, all manipulation features are disabled, except zooming. It is equivalent to LV_NoMove + LV_NoTracker + LV_NoSelection + LV_NoPlugins.

This constant has been introduced in version 0.27.

Python specific notes:
The object exposes a readable attribute 'LV_NoServices'. This is the getter.

LV_NoTracker

Signature: *[static,const]* unsigned int **LV_NoTracker**

Description: With this option, mouse position tracking is not supported

Use this value with the constructor's 'options' argument. This option is not useful currently as no mouse tracking support is provided.

This constant has been introduced in version 0.27.

Python specific notes:
The object exposes a readable attribute 'LV_NoTracker'. This is the getter.

LV_NoZoom

Signature: *[static,const]* unsigned int **LV_NoZoom**

Description: With this option, zooming is disabled

Use this value with the constructor's 'options' argument.

This constant has been introduced in version 0.27.

Python specific notes:
The object exposes a readable attribute 'LV_NoZoom'. This is the getter.

Replace

Signature: *[static,const]* LayoutView::SelectionMode **Replace**

Description: Replaces the existing selection

Python specific notes:
The object exposes a readable attribute 'Replace'. This is the getter.

Reset

Signature: *[static,const]* LayoutView::SelectionMode **Reset**

Description: Removes from any existing selection

Python specific notes:

The object exposes a readable attribute 'Reset'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

active_cellview

Signature: CellView **active_cellview**

Description: Gets the active cellview (shown in hierarchy browser)

This is a convenience method which is equivalent to cellview(active_cellview_index()).

This method has been introduced in version 0.19. Starting from version 0.25, the returned object can be manipulated which will have an immediate effect on the display.

active_cellview_index

Signature: *[const]* int **active_cellview_index**

Description: Gets the index of the active cellview (shown in hierarchy browser)

active_setview_index=

Signature: void **active_setview_index=** (int index)

Description: Makes the cellview with the given index the active one (shown in hierarchy browser)

See active_cellview_index.

This method has been renamed from set_active_cellview_index to active_cellview_index= in version 0.25. The original name is still available, but is deprecated.

Python specific notes:
The object exposes a writable attribute 'active_setview_index'. This is the setter.

add_l2ndb

Signature: unsigned int **add_l2ndb** (LayoutToNetlist ptr db)

Description: Adds the given netlist database to the view

Returns: The index of the database within the view (see l2ndb)

This method will add an existing database to the view. It will then appear in the netlist database browser. A similar method is create_l2ndb which will create a new database within the view.

This method has been added in version 0.26.

add_line_style

(1) Signature: unsigned int **add_line_style** (string name, unsigned int data, unsigned int bits)

Description: Adds a custom line style

name: The name under which this pattern will appear in the style editor

data: A bit set with the new line style pattern (bit 0 is the leftmost pixel)

bits: The number of bits to be used

Returns: The index of the newly created style, which can be used as the line style index of LayerProperties.

This method has been introduced in version 0.25.

(2) Signature: unsigned int **add_line_style** (string name, string string)

Description: Adds a custom line style from a string

name: The name under which this pattern will appear in the style editor

string: A string describing the bits of the pattern ('.' for missing pixel, '*' for a set pixel)

Returns: The index of the newly created style, which can be used as the line style index of LayerProperties.

This method has been introduced in version 0.25.

add_lvsdb

Signature: unsigned int **add_lvsdb** (LayoutVsSchematic ptr db)

Description: Adds the given database to the view

Returns: The index of the database within the view (see lvsdb)

This method will add an existing database to the view. It will then appear in the netlist database browser. A similar method is create_lvsdb which will create a new database within the view.

This method has been added in version 0.26.

add_missing_layers

Signature: void **add_missing_layers**

Description: Adds new layers to layer list

This method was introduced in version 0.19.

add_rdb

Signature: unsigned int **add_rdb** (ReportDatabase ptr db)

Description: Adds the given report database to the view

Returns: The index of the database within the view (see rdb)

This method will add an existing database to the view. It will then appear in the marker database browser. A similar method is create_rdb which will create a new database within the view.

This method has been added in version 0.26.

add_stipple

(1) Signature: unsigned int **add_stipple** (string name, unsigned int[] data, unsigned int bits)

Description: Adds a stipple pattern

name: The name under which this pattern will appear in the stipple editor

data: See above

bits: See above

Returns: The index of the newly created stipple pattern, which can be used as the dither pattern index of LayerProperties.

'data' is an array of unsigned integers describing the bits that make up the stipple pattern. If the array has less than 32 entries, the pattern will be repeated vertically. The number of bits used can be less than 32 bit which can be specified by the 'bits' parameter. Logically, the pattern will be put at the end of the list.

(2) Signature: unsigned int **add_stipple** (string name, string string)

Description: Adds a stipple pattern given by a string

name: The name under which this pattern will appear in the stipple editor

string: See above

Returns: The index of the newly created stipple pattern, which can be used as the dither pattern index of LayerProperties.

'string' is a string describing the pattern. It consists of one or more lines composed of '.' or '*' characters and separated by newline characters. A '.' is for a missing pixel and '*' for a set pixel. The length of each line must be the same. Blanks before or after each line are ignored.

This method has been introduced in version 0.25.

annotation

Signature: Annotation **annotation** (int id)

Description: Gets the annotation given by an ID

Returns a reference to the annotation given by the respective ID or an invalid annotation if the ID is not valid. Use Annotation#is_valid? to determine whether the returned annotation is valid or not.

The returned annotation is a 'live' object and changing it will update the view.

This method has been introduced in version 0.25.

annotation_templates

Signature: variant[][] **annotation_templates**

Description: Gets a list of Annotation objects representing the annotation templates.

Annotation templates are the rulers available in the ruler drop-down (preset ruler types). This method will fetch the templates available. This method returns triplets '(annotation, title, mode)'. The first member of the triplet is the annotation object representing the template. The second member is the title string displayed in the menu for this templates. The third member is the mode value (one of the RulerMode... constants - e.g RulerModeNormal).

The positions of the returned annotation objects are undefined.

This method has been introduced in version 0.28.

ascend

Signature: InstElement **ascend** (int index)

Description: Ascends upwards in the hierarchy.

Removes one element from the specific path of the cellview with the given index. Returns the element removed.

begin_layers

(1) Signature: *[const]* LayerPropertiesIterator **begin_layers**

Description: Begin iterator for the layers

This iterator delivers the layers of this view, either in a recursive or non-recursive fashion, depending which iterator increment methods are used. The iterator delivered by end_layers is the past-the-end iterator. It can be compared against a current iterator to check, if there are no further elements.

Starting from version 0.25, an alternative solution is provided with 'each_layer' which is based on the LayerPropertiesNodeRef class.

(2) Signature: *[const]* LayerPropertiesIterator **begin_layers** (unsigned int index)

Description: Begin iterator for the layers

This iterator delivers the layers of this view, either in a recursive or non-recursive fashion, depending which iterator increment methods are used. The iterator delivered by end_layers is the past-the-end iterator. It can be compared against a current iterator to check, if there are no further elements. This version addresses a specific list in a multi-tab layer properties arrangement with the "index" parameter. This method has been introduced in version 0.21.

bookmark_view

Signature: void **bookmark_view** (string name)

Description: Bookmarks the current view under the given name

name: The name under which to bookmark the current state

box

Signature: *[const]* DBox **box**

Description: Returns the displayed box in micron space

call_menu

Signature: void **call_menu** (string symbol)

Description: Calls the menu item with the provided symbol.

To obtain all symbols, use menu_symbols.

This method has been introduced in version 0.27.

cancel

Signature: void **cancel**

Description: Cancels all edit operations

This method will stop all pending edit operations (i.e. drag and drop) and cancel the current selection. Calling this method is useful to ensure there are no potential interactions with the script's functionality.

cellview

Signature: CellView **cellview** (unsigned int cv_index)

Description: Gets the cellview object for a given index

cv_index: The cellview index for which to get the object for

Starting with version 0.25, this method returns a CellView object that can be manipulated to directly reflect any changes in the display.

cellviews

Signature: *[const]* unsigned int **cellviews**

Description: Gets the number of cellviews

clear_annotations

Signature: void **clear_annotations**

Description: Clears all annotations on this view

clear_config

Signature: void **clear_config**

Description: Clears the local configuration parameters

See set_config for a description of the local configuration parameters.

clear_images

Signature: void **clear_images**

Description: Clear all images on this view

clear_layers

(1) Signature: void **clear_layers**

Description: Clears all layers

(2) Signature: void **clear_layers** (unsigned int index)

Description: Clears all layers for the given layer properties list

This version addresses a specific list in a multi-tab layer properties arrangement with the "index" parameter. This method has been introduced in version 0.21.

clear_line_styles

Signature: void **clear_line_styles**

Description: Removes all custom line styles

All line styles except the fixed ones are removed. If any of the custom styles is still used by the layers displayed, the results will be undefined. This method has been introduced in version 0.25.

clear_object_selection

Signature: *[const]* void **clear_object_selection**

Description: Clears the selection of geometrical objects (shapes or cell instances)

The selection of other objects (such as annotations and images) will not be affected.

This method has been introduced in version 0.24

clear_selection

Signature: void **clear_selection**

Description: Clears the selection of all objects (shapes, annotations, images ...)

This method has been introduced in version 0.26.2

clear_stipples

Signature: void **clear_stipples**

Description: Removes all custom line styles

All stipple pattern except the fixed ones are removed. If any of the custom stipple pattern is still used by the layers displayed, the results will be undefined.

clear_transactions

Signature: void **clear_transactions**

Description: Clears all transactions

Discard all actions in the undo buffer. After clearing that buffer, no undo is available. It is important to clear the buffer when making database modifications outside transactions, i.e after that modifications have been done. If failing to do so, 'undo' operations are likely to produce invalid results. This method was introduced in version 0.16.

clear_transient_selection

Signature: void **clear_transient_selection**

Description: Clears the transient selection (mouse-over hightlights) of all objects (shapes, annotations, images ...)

This method has been introduced in version 0.26.2

close

Signature: void **close**

Description: Closes the view

This method has been added in version 0.27.

commit

Signature: void **commit**

Description: Ends a transaction

See transaction for a detailed description of transactions. This method was introduced in version 0.16.

commit_config

Signature: void **commit_config**

Description: Commits the configuration settings

Some configuration options are queued for performance reasons and become active only after 'commit_config' has been called. After a sequence of set_config calls, this method should be called to activate the settings made by these calls.

This method has been introduced in version 0.25.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

create_l2ndb

Signature: unsigned int **create_l2ndb** (string name)

Description: Creates a new netlist database and returns the index of the new database

name:	The name of the new netlist database
Returns:	The index of the new database

This method returns an index of the new netlist database. Use l2ndb to get the actual object. If a netlist database with the given name already exists, a unique name will be created. The name will be replaced by the file name when a file is loaded into the netlist database.

This method has been added in version 0.26.

create_layout

(1) Signature: unsigned int **create_layout** (bool add_cellview)

Description: Creates a new, empty layout

Returns: The index of the cellview created.

The add_cellview parameter controls whether to create a new cellview (true) or clear all cellviews before (false).

This version will associate the new layout with the default technology.

(2) Signature: unsigned int **create_layout** (string tech, bool add_cellview)

Description: Create a new, empty layout and associate it with the given technology

Returns: The index of the cellview created.

The add_cellview parameter controls whether to create a new cellview (true) or clear all cellviews before (false).

This variant has been introduced in version 0.22.

(3) Signature: unsigned int **create_layout** (string tech, bool add_cellview, bool init_layers)

Description: Create a new, empty layout and associate it with the given technology

Returns: The index of the cellview created.

The add_cellview parameter controls whether to create a new cellview (true) or clear all cellviews before (false). This variant also allows one to control whether the layer properties are initialized (init_layers = true) or not (init_layers = false).

This variant has been introduced in version 0.22.

create_lvsdb

Signature: unsigned int **create_lvsdb** (string name)

Description: Creates a new netlist database and returns the index of the new database

name: The name of the new netlist database

Returns: The index of the new database

This method returns an index of the new netlist database. Use lvsdb to get the actual object. If a netlist database with the given name already exists, a unique name will be created. The name will be replaced by the file name when a file is loaded into the netlist database.

This method has been added in version 0.26.

create_measure_ruler

Signature: Annotation **create_measure_ruler** (const DPoint point, int ac = Annotation#AngleAny)

Description: Createas an auto-measure ruler at the given point.

point: The seed point where to create the auto-measure ruler

ac: The orientation constraints (determines the search direction too)

Returns: The new ruler object

The ac parameters takes one of the Angle... constants from Annotation.

This method will create a ruler with a measurement, looking to the sides of the seed point for visible layout in the vicinity. The angle constraint determines the main directions where to look.

If suitable edges are found, the method will pull a line between the closest edges. The ruler's endpoints will sit on these lines and the ruler's length will be the distance. Only visible layers will participate in the measurement.

The new ruler is inserted into the view already. It is created with the default style of rulers. If the measurement fails because there is no layout in the vicinity, a ruler with identical start and end points will be created.

This method was introduced in version 0.26.

create_rdb

Signature: unsigned int **create_rdb** (string name)

Description: Creates a new report database and returns the index of the new database

name:	The name of the new report database
Returns:	The index of the new database

This method returns an index of the new report database. Use rdb to get the actual object. If a report database with the given name already exists, a unique name will be created. The name will be replaced by the file name when a file is loaded into the report database.

current

Signature: *[static]* LayoutView ptr **current**

Description: Returns the current view

The current view is the one that is shown in the current tab. Returns nil if no layout is loaded.

This method has been introduced in version 0.23.

current_layer

Signature: *[const]* LayerPropertiesIterator **current_layer**

Description: Gets the current layer view

Returns the LayerPropertiesIterator pointing to the current layer view (the one that has the focus). If no layer view is active currently, a null iterator is returned.

Python specific notes:
The object exposes a readable attribute 'current_layer'. This is the getter.

current_layer=

Signature: void **current_layer=** (const LayerPropertiesIterator iter)

Description: Sets the current layer view

Specifies an LayerPropertiesIterator pointing to the new current layer view.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'current_layer'. This is the setter.

current_layer_list

Signature: *[const]* unsigned int **current_layer_list**

Description: Gets the index of the currently selected layer properties tab

This method has been introduced in version 0.21.

Python specific notes:
The object exposes a readable attribute 'current_layer_list'. This is the getter.

current_layer_list=

Signature: void **current_layer_list=** (unsigned int index)

Description: Sets the index of the currently selected layer properties tab

This method has been introduced in version 0.21.

Python specific notes:

	The object exposes a writable attribute 'current_layer_list'. This is the setter.
delete_layer	**(1) Signature**: void **delete_layer** (LayerPropertiesIterator iter) **Description**: Deletes the layer properties node specified by the iterator This method deletes the object that the iterator points to and invalidates the iterator since the object that the iterator points to is no longer valid. **(2) Signature**: void **delete_layer** (unsigned int index, LayerPropertiesIterator iter) **Description**: Deletes the layer properties node specified by the iterator This method deletes the object that the iterator points to and invalidates the iterator since the object that the iterator points to is no longer valid. This version addresses a specific list in a multi-tab layer properties arrangement with the "index" parameter. This method has been introduced in version 0.21.
delete_layer_list	**Signature**: void **delete_layer_list** (unsigned int index) **Description**: Deletes the given properties list At least one layer properties list must remain. This method may change the current properties list. This method has been introduced in version 0.21.
delete_layers	**(1) Signature**: void **delete_layers** (LayerPropertiesIterator[] iterators) **Description**: Deletes the layer properties nodes specified by the iterator This method deletes the nodes specifies by the iterators. This method is the most convenient way to delete multiple entries. This method has been added in version 0.22. **(2) Signature**: void **delete_layers** (unsigned int index, LayerPropertiesIterator[] iterators) **Description**: Deletes the layer properties nodes specified by the iterator This method deletes the nodes specifies by the iterators. This method is the most convenient way to delete multiple entries. This version addresses a specific list in a multi-tab layer properties arrangement with the "index" parameter. This method has been introduced in version 0.22.
descend	**Signature**: void **descend** (InstElement[] path, int index) **Description**: Descends further into the hierarchy. Adds the given path (given as an array of InstElement objects) to the specific path of the cellview with the given index. In effect, the cell addressed by the terminal of the new path components can be shown in the context of the upper cells, if the minimum hierarchy level is set to a negative value. The path is assumed to originate from the current cell and contain specific instances sorted from top to bottom.
destroy	**Signature**: void **destroy** **Description**: Explicitly destroys the object Use of this method is deprecated. Use _destroy instead Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

each_annotation

Signature: *[iter]* Annotation **each_annotation**

Description: Iterates over all annotations attached to this view

each_annotation_selected

Signature: *[const,iter]* Annotation **each_annotation_selected**

Description: Iterate over each selected annotation objects, yielding a Annotation object for each of them

This method was introduced in version 0.19.

each_image

Signature: *[iter]* Image **each_image**

Description: Iterate over all images attached to this view

With version 0.25, the objects returned by the iterator are references and can be manipulated to change their appearance.

each_image_selected

Signature: *[const,iter]* Image **each_image_selected**

Description: Iterate over each selected image object, yielding a Image object for each of them

This method was introduced in version 0.19.

each_layer

(1) Signature: *[iter]* LayerPropertiesNodeRef **each_layer**

Description: Hierarchically iterates over the layers in the first layer list

This iterator will recursively deliver the layers in the first layer list of the view. The objects presented by the iterator are LayerPropertiesNodeRef objects. They can be manipulated to apply changes to the layer settings or even the hierarchy of layers:

```
RBA::LayoutViewBase::current.each_layer do |lref|
  # lref is a RBA::LayerPropertiesNodeRef object
  lref.visible = false
end
```

This method was introduced in version 0.25.

(2) Signature: *[iter]* LayerPropertiesNodeRef **each_layer** (unsigned int layer_list)

Description: Hierarchically iterates over the layers in the given layer list

This version of this method allows specification of the layer list to be iterated over. The layer list is specified by its index which is a value between 0 and num_layer_lists-1.For details see the parameter-less version of this method.

This method was introduced in version 0.25.

each_object_selected

Signature: *[const,iter]* ObjectInstPath **each_object_selected**

Description: Iterates over each selected geometrical object, yielding a ObjectInstPath object for each of them

This iterator will deliver const objects - they cannot be modified. In order to modify the selection, create a copy of the ObjectInstPath objects, modify them and install the new selection using select_object or object_selection=.

Another way of obtaining the selection is object_selection, which returns an array of ObjectInstPath objects.

each_object_selected_transient

Signature: *[const,iter]* ObjectInstPath **each_object_selected_transient**

Description: Iterates over each geometrical objects in the transient selection, yielding a ObjectInstPath object for each of them

This method was introduced in version 0.18.

enable_edits

Signature: void **enable_edits** (bool enable)

Description: Enables or disables edits

enable: Enable edits if set to true

This method allows putting the view into read-only mode by disabling all edit functions. For doing so, this method has to be called with a 'false' argument. Calling it with a 'true' parameter enables all edits again. This method must not be confused with the edit/viewer mode. The LayoutView's enable_edits method is intended to temporarily disable all menu entries and functions which could allow the user to alter the database. In 0.25, this method has been moved from MainWindow to LayoutView.

end_layers

(1) Signature: *[const]* LayerPropertiesIterator **end_layers**

Description: End iterator for the layers

See begin_layers for a description about this iterator

(2) Signature: *[const]* LayerPropertiesIterator **end_layers** (unsigned int index)

Description: End iterator for the layers

See begin_layers for a description about this iterator This version addresses a specific list in a multi-tab layer properties arrangement with the "index" parameter. This method has been introduced in version 0.21.

erase_annotation

Signature: void **erase_annotation** (int id)

Description: Erases the annotation given by the id

Deletes an existing annotation given by the id parameter. The id of an annotation can be obtained through Annotation#id.

This method has been introduced in version 0.24. Starting with version 0.25, the annotation's Annotation#delete method can also be used to delete an annotation.

erase_cellview

Signature: void **erase_cellview** (unsigned int index)

Description: Erases the cellview with the given index

This closes the given cellview and unloads the layout associated with it, unless referred to by another cellview.

erase_image

Signature: void **erase_image** (unsigned long id)

Description: Erase the given image

id: The id of the object to erase

Erases the image with the given Id. The Id can be obtained with if "id" method of the image object.

This method has been introduced in version 0.20.

With version 0.25, Image#delete can be used to achieve the same results.

expand_layer_properties

(1) Signature: void **expand_layer_properties**

Description: Expands the layer properties for all tabs

This method will expand all wildcard specifications in the layer properties by iterating over the specified objects (i.e. layers, cellviews) and by replacing default colors and stipples by the ones specified with the palettes.

This method was introduced in version 0.21.

(2) Signature: void **expand_layer_properties** (unsigned int index)

Description: Expands the layer properties for the given tab

This method will expand all wildcard specifications in the layer properties by iterating over the specified objects (i.e. layers, cellviews) and by replacing default colors and stipples by the ones specified with the palettes.

This method was introduced in version 0.21.

get_config

Signature: *[const]* string **get_config** (string name)

Description: Gets the value of a local configuration parameter

name: The name of the configuration parameter whose value shall be obtained (a string)

Returns: The value of the parameter

See set_config for a description of the local configuration parameters.

get_config_names

Signature: string[] **get_config_names**

Description: Gets the configuration parameter names

Returns: A list of configuration parameter names

This method returns the names of all known configuration parameters. These names can be used to get and set configuration parameter values.

This method was introduced in version 0.25.

get_current_cell_path

Signature: *[const]* unsigned int[] **get_current_cell_path** (int cv_index)

Description: Gets the cell path of the current cell

cv_index: The cellview index for which to get the current path from (usually this will be the active cellview index)

Use of this method is deprecated

The current cell is the one highlighted in the browser with the focus rectangle. The current path is returned for the cellview given by cv_index. The cell path is a list of cell indices from the top cell to the current cell.

This method is was deprecated in version 0.25 since from then, the CellView object can be used to obtain an manipulate the selected cell.

get_image

Signature: QImage **get_image** (unsigned int width, unsigned int height)

Description: Gets the layout image as a QImage

width: The width of the image to render in pixel.

height: The height of the image to render in pixel.

The image contains the current scene (layout, annotations etc.). The image is drawn synchronously with the given width and height. Drawing may take some time.

get_image_with_options

Signature: QImage **get_image_with_options** (unsigned int width, unsigned int height, int linewidth = 0, int oversampling = 0, double resolution = 0, const DBox target = current, bool monochrome = false)

Description: Gets the layout image as a QImage (with options)

width: The width of the image to render in pixel.

height: The height of the image to render in pixel.

linewidth: The width of a line in pixels (usually 1) or 0 for default.

oversampling: The oversampling factor (1..3) or 0 for default.

resolution: The resolution (pixel size compared to a screen pixel size, i.e 1/oversampling) or 0 for default.

target_box: The box to draw or an empty box for default.

monochrome: If true, monochrome images will be produced.

The image contains the current scene (layout, annotations etc.). The image is drawn synchronously with the given width and height. Drawing may take some time. Monochrome images don't have background or annotation objects currently.

This method has been introduced in version 0.23.10.

get_line_style

Signature: string **get_line_style** (unsigned int index)

Description: Gets the line style string for the style with the given index

This method will return the line style string for the style with the given index. The format of the string is the same than the string accepted by add_line_style. An empty string corresponds to 'solid line'.

This method has been introduced in version 0.25.

get_pixels

Signature: PixelBuffer **get_pixels** (unsigned int width, unsigned int height)

Description: Gets the layout image as a PixelBuffer

width: The width of the image to render in pixel.

height: The height of the image to render in pixel.

The image contains the current scene (layout, annotations etc.). The image is drawn synchronously with the given width and height. Drawing may take some time. This method has been introduced in 0.28.

get_pixels_with_options

Signature: PixelBuffer **get_pixels_with_options** (unsigned int width, unsigned int height, int linewidth = 0, int oversampling = 0, double resolution = 0, const DBox target = current)

Description: Gets the layout image as a PixelBuffer (with options)

width: The width of the image to render in pixel.

height: The height of the image to render in pixel.

linewidth: The width of a line in pixels (usually 1) or 0 for default.

oversampling:	The oversampling factor (1..3) or 0 for default.
resolution:	The resolution (pixel size compared to a screen pixel size, i.e 1/oversampling) or 0 for default.
target_box:	The box to draw or an empty box for default.

The image contains the current scene (layout, annotations etc.). The image is drawn synchronously with the given width and height. Drawing may take some time. This method has been introduced in 0.28.

get_pixels_with_options_mon

Signature: BitmapBuffer **get_pixels_with_options_mono** (unsigned int width, unsigned int height, int linewidth = 0, const DBox target = current)

Description: Gets the layout image as a PixelBuffer (with options)

width:	The width of the image to render in pixel.
height:	The height of the image to render in pixel.
linewidth:	The width of a line in pixels (usually 1) or 0 for default.
target_box:	The box to draw or an empty box for default.

The image contains the current scene (layout, annotations etc.). The image is drawn synchronously with the given width and height. Drawing may take some time. Monochrome images don't have background or annotation objects currently.

This method has been introduced in 0.28.

get_screenshot

Signature: QImage **get_screenshot**

Description: Gets a screenshot as a QImage

Getting the image requires the drawing to be complete. Ideally, synchronous mode is switched on for the application to guarantee this condition. The image will have the size of the viewport showing the current layout.

get_screenshot_pixels

Signature: PixelBuffer **get_screenshot_pixels**

Description: Gets a screenshot as a PixelBuffer

Getting the image requires the drawing to be complete. Ideally, synchronous mode is switched on for the application to guarantee this condition. The image will have the size of the viewport showing the current layout. This method has been introduced in 0.28.

get_stipple

Signature: string **get_stipple** (unsigned int index)

Description: Gets the stipple pattern string for the pattern with the given index

This method will return the stipple pattern string for the pattern with the given index. The format of the string is the same than the string accepted by add_stipple.

This method has been introduced in version 0.25.

has_annotation_selection?

Signature: *[const]* bool **has_annotation_selection?**

Description: Returns true, if annotations (rulers) are selected in this view

This method was introduced in version 0.19.

has_image_selection?

Signature: *[const]* bool **has_image_selection?**

Description: Returns true, if images are selected in this view

This method was introduced in version 0.19.

has_object_selection?

Signature: *[const]* bool **has_object_selection?**

Description: Returns true, if geometrical objects (shapes or cell instances) are selected in this view

has_selection?

Signature: bool **has_selection?**

Description: Indicates whether any objects are selected

This method has been introduced in version 0.27

has_transient_object_selectio

Signature: *[const]* bool **has_transient_object_selection?**

Description: Returns true, if geometrical objects (shapes or cell instances) are selected in this view in the transient selection

The transient selection represents the objects selected when the mouse hovers over the layout windows. This selection is not used for operations but rather to indicate which object would be selected if the mouse is clicked.

This method was introduced in version 0.18.

hide_cell

Signature: void **hide_cell** (unsigned int cell_index, int cv_index)

Description: Hides the given cell for the given cellview

icon_for_layer

Signature: PixelBuffer **icon_for_layer** (const LayerPropertiesIterator iter, unsigned int w, unsigned int h, double dpr, unsigned int di_off = 0, bool no_state = false)

Description: Creates an icon pixmap for the given layer.

The icon will have size w times h pixels multiplied by the device pixel ratio (dpr). The dpr is The number of physical pixels per logical pixels on high-DPI displays.

'di_off' will shift the dither pattern by the given number of (physical) pixels. If 'no_state' is true, the icon will not reflect visibility or validity states but rather the display style.

This method has been introduced in version 0.28.

image

Signature: Image **image** (unsigned long id)

Description: Gets the image given by an ID

Returns a reference to the image given by the respective ID or an invalid image if the ID is not valid. Use Image#is_valid? to determine whether the returned image is valid or not.

The returned image is a 'live' object and changing it will update the view.

This method has been introduced in version 0.25.

init_layer_properties

Signature: *[const]* void **init_layer_properties** (LayerProperties props)

Description: Fills the layer properties for a new layer

props: The layer properties object to initialize.

This method initializes a layer properties object's color and stipples according to the defaults for the given layer source specification. The layer's source must be set already on the layer properties object.

This method was introduced in version 0.19.

insert_annotation

Signature: void **insert_annotation** (Annotation ptr obj)

Description: Inserts an annotation object into the given view

Inserts a new annotation into the view. Existing annotation will remain. Use clear_annotations to delete them before inserting new ones. Use replace_annotation to replace an existing one with a new one. Starting with version 0.25 this method modifies self's ID to reflect the ID of the ruler created. After an annotation is inserted into the view, it can be modified and the changes of properties will become reflected immediately in the view.

insert_image

Signature: void **insert_image** (Image obj)

Description: Insert an image object into the given view

Insert the image object given by obj into the view.

With version 0.25, this method will attach the image object to the view and the image object will become a 'live' object - i.e. changes to the object will change the appearance of the image on the screen.

insert_layer

(1) Signature: LayerPropertiesNodeRef **insert_layer** (const LayerPropertiesIterator iter, const LayerProperties node = LayerProperties())

Description: Inserts the given layer properties node into the list before the given position

This method inserts the new properties node before the position given by "iter" and returns a const reference to the element created. The iterator that specified the position will remain valid after the node was inserted and will point to the newly created node. It can be used to add further nodes. To add children to the node inserted, use iter.last_child as insertion point for the next insert operations.

Since version 0.22, this method accepts LayerProperties and LayerPropertiesNode objects. A LayerPropertiesNode object can contain a hierarchy of further nodes. Since version 0.26 the node parameter is optional and the reference returned by this method can be used to set the properties of the new node.

(2) Signature: LayerPropertiesNodeRef **insert_layer** (unsigned int index, const LayerPropertiesIterator iter, const LayerProperties node = LayerProperties())

Description: Inserts the given layer properties node into the list before the given position

This version addresses a specific list in a multi-tab layer properties arrangement with the "index" parameter. This method inserts the new properties node before the position given by "iter" and returns a const reference to the element created. The iterator that specified the position will remain valid after the node was inserted and will point to the newly created node. It can be used to add further nodes. This method has been introduced in version 0.21. Since version 0.22, this method accepts LayerProperties and LayerPropertiesNode objects. A LayerPropertiesNode object can contain a hierarchy of further nodes. Since version 0.26 the node parameter is optional and the reference returned by this method can be used to set the properties of the new node.

insert_layer_list

Signature: void **insert_layer_list** (unsigned int index)

Description: Inserts a new layer properties list at the given index

This method inserts a new tab at the given position. The current layer properties list will be changed to the new list. This method has been introduced in version 0.21.

is_cell_hidden?

Signature: *[const]* bool **is_cell_hidden?** (unsigned int cell_index, int cv_index)

Description: Returns true, if the cell is hidden

Returns: True, if the cell with "cell_index" is hidden for the cellview "cv_index"

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_dirty?

Signature: bool **is_dirty?**

Description: Gets a flag indicating whether one of the layouts displayed needs saving

A layout is 'dirty' if it is modified and needs saving. This method returns true if this is the case for at least one of the layouts shown in the view.

This method has been introduced in version 0.29.

is_editable?

Signature: *[const]* bool **is_editable?**

Description: Returns true if the view is in editable mode

This read-only attribute has been added in version 0.27.5.

is_transacting?

Signature: bool **is_transacting?**

Description: Indicates if a transaction is ongoing

See transaction for a detailed description of transactions. This method was introduced in version 0.16.

l2ndb

Signature: LayoutToNetlist ptr **l2ndb** (int index)

Description: Gets the netlist database with the given index

Returns: The LayoutToNetlist object or nil if the index is not valid

This method has been added in version 0.26.

load_layer_props

(1) Signature: void **load_layer_props** (string fn)

Description: Loads the layer properties

fn: The file name of the .lyp file to load

Load the layer properties from the file given in "fn"

(2) Signature: void **load_layer_props** (string fn, bool add_default)

Description: Loads the layer properties with options

fn: The file name of the .lyp file to load

add_default: If true, default layers will be added for each other layer in the layout

Load the layer properties from the file given in "fn". This version allows one to specify whether defaults should be used for all other layers by setting "add_default" to true.

This variant has been added on version 0.21.

(3) Signature: void **load_layer_props** (string fn, int cv_index, bool add_default)

Description: Loads the layer properties with options

fn: The file name of the .lyp file to load

cv_index: See description text

add_default: If true, default layers will be added for each other layer in the layout

Load the layer properties from the file given in "fn". This version allows one to specify whether defaults should be used for all other layers by setting "add_default" to true. It can be used to load the layer properties for a specific cellview by setting "cv_index" to the index for which the layer properties file should be applied. All present definitions for this layout will be removed before the properties file is loaded. "cv_index" can be set to -1. In that case, the layer properties file is applied to each of the layouts individually.

Note that this version will override all cellview index definitions in the layer properties file.

This variant has been added on version 0.21.

load_layout

(1) Signature: unsigned int **load_layout** (string filename, const LoadLayoutOptions options, string technology, bool add_cellview = true)

Description: Loads a (new) file into the layout view with the given technology

Returns: The index of the cellview loaded.

Loads the file given by the "filename" parameter and associates it with the given technology. The options specify various options for reading the file. The add_cellview param controls whether to create a new cellview (true) or clear all cellviews before (false).

This version has been introduced in version 0.22. The 'add_cellview' argument has been made optional in version 0.28.

(2) Signature: unsigned int **load_layout** (string filename, const LoadLayoutOptions options, bool add_cellview = true)

Description: Loads a (new) file into the layout view

Returns: The index of the cellview loaded.

Loads the file given by the "filename" parameter. The options specify various options for reading the file. The add_cellview param controls whether to create a new cellview (true) or clear all cellviews before (false).

This method has been introduced in version 0.18. The 'add_cellview' argument has been made optional in version 0.28.

(3) Signature: unsigned int **load_layout** (string filename, string technology, bool add_cellview = true)

Description: Loads a (new) file into the layout view with the given technology

Returns: The index of the cellview loaded.

Loads the file given by the "filename" parameter and associates it with the given technology. The add_cellview param controls whether to create a new cellview (true) or clear all cellviews before (false).

This version has been introduced in version 0.22. The 'add_cellview' argument has been made optional in version 0.28.

(4) Signature: unsigned int **load_layout** (string filename, bool add_cellview = true)

Description: Loads a (new) file into the layout view

Returns: The index of the cellview loaded. The 'add_cellview' argument has been made optional in version 0.28.

Loads the file given by the "filename" parameter. The add_cellview param controls whether to create a new cellview (true) or clear all cellviews before (false).

lvsdb

Signature: LayoutVsSchematic ptr **lvsdb** (unsigned int index)

Description: Gets the netlist database with the given index

Returns: The LayoutVsSchematic object or nil if the index is not valid

This method has been added in version 0.26.

max_hier

Signature: void **max_hier**

Description: Selects all hierarchy levels available

Show the layout in full depth down to the deepest level of hierarchy. This method may cause a redraw.

max_hier_levels

Signature: *[const]* int **max_hier_levels**

Description: Returns the maximum hierarchy level up to which to display geometries

Returns: The maximum level up to which to display geometries

Python specific notes:
The object exposes a readable attribute 'max_hier_levels'. This is the getter.

max_hier_levels=

Signature: void **max_hier_levels=** (int level)

Description: Sets the maximum hierarchy level up to which to display geometries

level: The maximum level below which to display something

This methods allows setting the maximum hierarchy below which to display geometries.This method may cause a redraw if required.

Python specific notes:
The object exposes a writable attribute 'max_hier_levels'. This is the setter.

menu

Signature: AbstractMenu ptr **menu**

Description: Gets the AbstractMenu associated with this view.

In normal UI application mode this is the main window's view. For a detached view or in non-UI applications this is the view's private menu.

This method has been introduced in version 0.28.

menu_symbols

Signature: *[static]* string[] **menu_symbols**

Description: Gets all available menu symbols (see call_menu).

NOTE: currently this method delivers a superset of all available symbols. Depending on the context, no all symbols may trigger actual functionality.

This method has been introduced in version 0.27.

min_hier_levels

Signature: *[const]* int **min_hier_levels**

Description: Returns the minimum hierarchy level at which to display geometries

Returns: The minimum level at which to display geometries

Python specific notes:
The object exposes a readable attribute 'min_hier_levels'. This is the getter.

min_hier_levels=

Signature: void **min_hier_levels=** (int level)

Description: Sets the minimum hierarchy level at which to display geometries

level: The minimum level above which to display something

This methods allows setting the minimum hierarchy level above which to display geometries.This method may cause a redraw if required.

Python specific notes:
The object exposes a writable attribute 'min_hier_levels'. This is the setter.

mode_name

Signature: *[const]* string **mode_name**

Description: Gets the name of the current mode.

See switch_mode about a method to change the mode and mode_names for a method to retrieve all available mode names.

This method has been introduced in version 0.28.

mode_names

Signature: *[const]* string[] **mode_names**

Description: Gets the names of the available modes.

This method allows asking the view for the available mode names for switch_mode and for the value returned by mode.

This method has been introduced in version 0.28.

netlist_browser

Signature: NetlistBrowserDialog ptr **netlist_browser**

Description: Gets the netlist browser object for the given layout view

This method has been added in version 0.27.

new

Signature: *[static]* new LayoutView ptr **new** (bool editable = false, Manager ptr manager = nil, unsigned int options = 0)

Description: Creates a standalone view

editable:	True to make the view editable
manager:	The Manager object to enable undo/redo
options:	A combination of the values in the LV_... constants from LayoutViewBase

This constructor is for special purposes only. To create a view in the context of a main window, use MainWindow#create_view and related methods.

This constructor has been introduced in version 0.25. It has been enhanced with the arguments in version 0.27.

Python specific notes:
This method is the default initializer of the object.

num_l2ndbs

Signature: *[const]* unsigned int **num_l2ndbs**

Description: Gets the number of netlist databases loaded into this view

Returns: The number of LayoutToNetlist objects present in this view

This method has been added in version 0.26.

num_layer_lists

Signature: *[const]* unsigned int **num_layer_lists**

Description: Gets the number of layer properties tabs present

This method has been introduced in version 0.23.

num_rdbs

Signature: *[const]* unsigned int **num_rdbs**

Description: Gets the number of report databases loaded into this view

Returns: The number of ReportDatabase objects present in this view

object_selection

Signature: *[const]* ObjectInstPath[] **object_selection**

Description: Returns a list of selected objects

This method will deliver an array of ObjectInstPath objects listing the selected geometrical objects. Other selected objects such as annotations and images will not be contained in that list.

The list returned is an array of copies of ObjectInstPath objects. They can be modified, but they will become a new selection only after re-introducing them into the view through object_selection= or select_object.

Another way of obtaining the selected objects is each_object_selected.

This method has been introduced in version 0.24.

Python specific notes:
The object exposes a readable attribute 'object_selection'. This is the getter.

object_selection=

Signature: *[const]* void **object_selection=** (ObjectInstPath[] sel)

Description: Sets the list of selected objects

This method will set the selection of geometrical objects such as shapes and instances. It is the setter which complements the object_selection method.

Another way of setting the selection is through clear_object_selection and select_object.

This method has been introduced in version 0.24.

Python specific notes:
The object exposes a writable attribute 'object_selection'. This is the setter.

on_active_cellview_changed

Signature: *[signal]* void **on_active_cellview_changed**

Description: An event indicating that the active cellview has changed

If the active cellview is changed by selecting a new one from the drop-down list, this event is triggered. When this event is triggered, the cellview has already been changed. Before version 0.25 this event was based on the observer pattern obsolete now. The corresponding methods (add_active_cellview_changed/remove_active_cellview_changed) have been removed in 0.25.

Python specific notes:
The object exposes a readable attribute 'on_active_cellview_changed'. This is the getter.
The object exposes a writable attribute 'on_active_cellview_changed'. This is the setter.

on_annotation_changed

Signature: *[signal]* void **on_annotation_changed** (int id)

Description: A event indicating that an annotation has been modified

The argument of the event is the ID of the annotation that was changed. This event has been added in version 0.25.

Python specific notes:
The object exposes a readable attribute 'on_annotation_changed'. This is the getter.
The object exposes a writable attribute 'on_annotation_changed'. This is the setter.

on_annotation_selection_cha

Signature: *[signal]* void **on_annotation_selection_changed**

Description: A event indicating that the annotation selection has changed

This event has been added in version 0.25.

	Python specific notes: The object exposes a readable attribute 'on_annotation_selection_changed'. This is the getter. The object exposes a writable attribute 'on_annotation_selection_changed'. This is the setter.
on_annotations_changed	**Signature**: *[signal]* void **on_annotations_changed** **Description**: A event indicating that annotations have been added or removed This event has been added in version 0.25. **Python specific notes:** The object exposes a readable attribute 'on_annotations_changed'. This is the getter. The object exposes a writable attribute 'on_annotations_changed'. This is the setter.
on_apply_technology	**Signature**: *[signal]* void **on_apply_technology** (int cellview_index) **Description**: An event indicating that a cellview has requested a new technology If the technology of a cellview is changed, this event is triggered. The integer parameter of this event will indicate the cellview that has changed. This event has been introduced in version 0.28. **Python specific notes:** The object exposes a readable attribute 'on_apply_technology'. This is the getter. The object exposes a writable attribute 'on_apply_technology'. This is the setter.
on_cell_visibility_changed	**Signature**: *[signal]* void **on_cell_visibility_changed** **Description**: An event indicating that the visibility of one or more cells has changed This event is triggered after the visibility of one or more cells has changed. Before version 0.25 this event was based on the observer pattern obsolete now. The corresponding methods (add_cell_visibility_observer/remove_cell_visibility_observer) have been removed in 0.25. **Python specific notes:** The object exposes a readable attribute 'on_cell_visibility_changed'. This is the getter. The object exposes a writable attribute 'on_cell_visibility_changed'. This is the setter.
on_cellview_changed	**Signature**: *[signal]* void **on_cellview_changed** (int cellview_index) **Description**: An event indicating that a cellview has changed If a cellview is modified, this event is triggered. When this event is triggered, the cellview have already been changed. The integer parameter of this event will indicate the cellview that has changed. Before version 0.25 this event was based on the observer pattern obsolete now. The corresponding methods (add_cellview_observer/remove_cellview_observer) have been removed in 0.25. **Python specific notes:** The object exposes a readable attribute 'on_cellview_changed'. This is the getter. The object exposes a writable attribute 'on_cellview_changed'. This is the setter.
on_cellviews_changed	**Signature**: *[signal]* void **on_cellviews_changed** **Description**: An event indicating that the cellview collection has changed If new cellviews are added or cellviews are removed, this event is triggered. When this event is triggered, the cellviews have already been changed. Before version 0.25 this event was based on the observer pattern obsolete now. The corresponding methods (add_cellview_list_observer/ remove_cellview_list_observer) have been removed in 0.25.

Python specific notes:
The object exposes a readable attribute 'on_cellviews_changed'. This is the getter.
The object exposes a writable attribute 'on_cellviews_changed'. This is the setter.

on_close

Signature: *[signal]* void **on_close**

Description: A event indicating that the view is about to close

This event is triggered when the view is going to be closed entirely.

It has been added in version 0.25.

Python specific notes:
The object exposes a readable attribute 'on_close'. This is the getter.
The object exposes a writable attribute 'on_close'. This is the setter.

on_current_layer_list_changed

Signature: *[signal]* void **on_current_layer_list_changed** (int index)

Description: An event indicating the current layer list (the selected tab) has changed

index: The index of the new current layer list

This event is triggered after the current layer list was changed - i.e. a new tab was selected.

This event was introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'on_current_layer_list_changed'. This is the getter.
The object exposes a writable attribute 'on_current_layer_list_changed'. This is the setter.

on_file_open

Signature: *[signal]* void **on_file_open**

Description: An event indicating that a file was opened

If a file is loaded, this event is triggered. When this event is triggered, the file was already loaded and the new file is the new active cellview. Despite its name, this event is also triggered if a layout object is loaded into the view.

Before version 0.25 this event was based on the observer pattern obsolete now. The corresponding methods (add_file_open_observer/remove_file_open_observer) have been removed in 0.25.

Python specific notes:
The object exposes a readable attribute 'on_file_open'. This is the getter.
The object exposes a writable attribute 'on_file_open'. This is the setter.

on_hide

Signature: *[signal]* void **on_hide**

Description: A event indicating that the view is going to become invisible

It has been added in version 0.25.

Python specific notes:
The object exposes a readable attribute 'on_hide'. This is the getter.
The object exposes a writable attribute 'on_hide'. This is the setter.

on_image_changed

Signature: *[signal]* void **on_image_changed** (int id)

Description: A event indicating that an image has been modified

The argument of the event is the ID of the image that was changed. This event has been added in version 0.25.

Python specific notes:
The object exposes a readable attribute 'on_image_changed'. This is the getter.
The object exposes a writable attribute 'on_image_changed'. This is the setter.

on_image_selection_changed

Signature: *[signal]* void **on_image_selection_changed**

Description: A event indicating that the image selection has changed

This event has been added in version 0.25.

Python specific notes:
The object exposes a readable attribute 'on_image_selection_changed'. This is the getter.
The object exposes a writable attribute 'on_image_selection_changed'. This is the setter.

on_images_changed

Signature: *[signal]* void **on_images_changed**

Description: A event indicating that images have been added or removed

This event has been added in version 0.25.

Python specific notes:
The object exposes a readable attribute 'on_images_changed'. This is the getter.
The object exposes a writable attribute 'on_images_changed'. This is the setter.

on_l2ndb_list_changed

Signature: *[signal]* void **on_l2ndb_list_changed**

Description: An event that is triggered the list of netlist databases is changed

If a netlist database is added or removed, this event is triggered.

This method has been added in version 0.26.

Python specific notes:
The object exposes a readable attribute 'on_l2ndb_list_changed'. This is the getter.
The object exposes a writable attribute 'on_l2ndb_list_changed'. This is the setter.

on_layer_list_changed

Signature: *[signal]* void **on_layer_list_changed** (int flags)

Description: An event indicating that the layer list has changed

This event is triggered after the layer list has changed its configuration. The integer argument gives a hint about the nature of the changed: Bit 0 is set, if the properties (visibility, color etc.) of one or more layers have changed. Bit 1 is set if the hierarchy has changed. Bit 2 is set, if layer names have changed. Before version 0.25 this event was based on the observer pattern obsolete now. The corresponding methods (add_layer_list_observer/remove_layer_list_observer) have been removed in 0.25.

Python specific notes:
The object exposes a readable attribute 'on_layer_list_changed'. This is the getter.
The object exposes a writable attribute 'on_layer_list_changed'. This is the setter.

on_layer_list_deleted

Signature: *[signal]* void **on_layer_list_deleted** (int index)

Description: An event indicating that a layer list (a tab) has been removed

index: The index of the layer list that was removed

This event is triggered after the layer list has been removed - i.e. a tab was deleted.

This event was introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'on_layer_list_deleted'. This is the getter.
The object exposes a writable attribute 'on_layer_list_deleted'. This is the setter.

on_layer_list_inserted

Signature: *[signal]* void **on_layer_list_inserted** (int index)

Description: An event indicating that a layer list (a tab) has been inserted

index: The index of the layer list that was inserted

	This event is triggered after the layer list has been inserted - i.e. a new tab was created. This event was introduced in version 0.25. **Python specific notes:** The object exposes a readable attribute 'on_layer_list_inserted'. This is the getter. The object exposes a writable attribute 'on_layer_list_inserted'. This is the setter.
on_rdb_list_changed	**Signature**: *[signal]* void **on_rdb_list_changed** **Description**: An event that is triggered the list of report databases is changed If a report database is added or removed, this event is triggered. This event was translated from the Observer pattern to an event in version 0.25. **Python specific notes:** The object exposes a readable attribute 'on_rdb_list_changed'. This is the getter. The object exposes a writable attribute 'on_rdb_list_changed'. This is the setter.
on_selection_changed	**Signature**: *[signal]* void **on_selection_changed** **Description**: An event that is triggered if the selection is changed If the selection changed, this event is triggered. This event was translated from the Observer pattern to an event in version 0.25. **Python specific notes:** The object exposes a readable attribute 'on_selection_changed'. This is the getter. The object exposes a writable attribute 'on_selection_changed'. This is the setter.
on_show	**Signature**: *[signal]* void **on_show** **Description**: A event indicating that the view is going to become visible It has been added in version 0.25. **Python specific notes:** The object exposes a readable attribute 'on_show'. This is the getter. The object exposes a writable attribute 'on_show'. This is the setter.
on_transient_selection_chang	**Signature**: *[signal]* void **on_transient_selection_changed** **Description**: An event that is triggered if the transient selection is changed If the transient selection is changed, this event is triggered. The transient selection is the highlighted selection when the mouse hovers over some object(s). This event was translated from the Observer pattern to an event in version 0.25. **Python specific notes:** The object exposes a readable attribute 'on_transient_selection_changed'. This is the getter. The object exposes a writable attribute 'on_transient_selection_changed'. This is the setter.
on_viewport_changed	**Signature**: *[signal]* void **on_viewport_changed** **Description**: An event indicating that the viewport (the visible rectangle) has changed This event is triggered after a new display rectangle was chosen - for example, because the user zoomed into the layout. Before version 0.25 this event was based on the observer pattern obsolete now. The corresponding methods (add_viewport_changed_observer/remove_viewport_changed_observer) have been removed in 0.25. **Python specific notes:** The object exposes a readable attribute 'on_viewport_changed'. This is the getter.

The object exposes a writable attribute 'on_viewport_changed'. This is the setter.

open_d25_view

Signature: D25View ptr **open_d25_view**
Description: Opens the 2.5d view window and returns a reference to the D25View object.
This method has been introduced in version 0.28.

pan_center

Signature: void **pan_center** (const DPoint p)
Description: Pans to the given point
The window is positioned such that "p" becomes the new center

pan_down

Signature: void **pan_down**
Description: Pans down

pan_left

Signature: void **pan_left**
Description: Pans to the left

pan_right

Signature: void **pan_right**
Description: Pans to the right

pan_up

Signature: void **pan_up**
Description: Pans upward

rdb

Signature: ReportDatabase ptr **rdb** (int index)
Description: Gets the report database with the given index
Returns: The ReportDatabase object or nil if the index is not valid

register_annotation_template

Signature: void **register_annotation_template** (const Annotation annotation, string title, int mode = RulerModeNormal)
Description: Registers the given annotation as a template for this particular view
title: The title to use for the ruler template
mode: The mode the ruler will be created in (see Ruler... constants)
@annotation The annotation to use for the template (positions are ignored)
See Annotation#register_template for a method doing the same on application level. This method is hardly useful normally, but can be used when customizing layout views as individual widgets.
This method has been added in version 0.28.

reload_layout

Signature: void **reload_layout** (unsigned int cv)
Description: Reloads the given cellview
cv: The index of the cellview to reload

remove_l2ndb

Signature: void **remove_l2ndb** (unsigned int index)
Description: Removes a netlist database with the given index
The: index of the netlist database to remove from this view

This method has been added in version 0.26.

remove_line_style

Signature: void **remove_line_style** (unsigned int index)

Description: Removes the line style with the given index

The line styles with an index less than the first custom style. If a style is removed that is still used, the results are undefined.

This method has been introduced in version 0.25.

remove_rdb

Signature: void **remove_rdb** (unsigned int index)

Description: Removes a report database with the given index

The: index of the report database to remove from this view

remove_stipple

Signature: void **remove_stipple** (unsigned int index)

Description: Removes the stipple pattern with the given index

The pattern with an index less than the first custom pattern cannot be removed. If a stipple pattern is removed that is still used, the results are undefined.

remove_unused_layers

Signature: void **remove_unused_layers**

Description: Removes unused layers from layer list

This method was introduced in version 0.19.

rename_cellview

Signature: void **rename_cellview** (string name, int index)

Description: Renames the cellview with the given index

If the name is not unique, a unique name will be constructed from the name given. The name may be different from the filename but is associated with the layout object. If a layout is shared between multiple cellviews (which may happen due to a clone of the layout view for example), all cellviews are renamed.

rename_layer_list

Signature: void **rename_layer_list** (unsigned int index, string name)

Description: Sets the title of the given layer properties tab

This method has been introduced in version 0.21.

replace_annotation

Signature: void **replace_annotation** (int id, const Annotation obj)

Description: Replaces the annotation given by the id with the new one

Replaces an existing annotation given by the id parameter with the new one. The id of an annotation can be obtained through Annotation#id.

This method has been introduced in version 0.24.

replace_image

Signature: void **replace_image** (unsigned long id, Image new_obj)

Description: Replace an image object with the new image

id: The id of the object to replace

new_obj: The new object to replace the old one

Replaces the image with the given Id with the new object. The Id can be obtained with if "id" method of the image object.

This method has been introduced in version 0.20.

replace_l2ndb

Signature: unsigned int **replace_l2ndb** (unsigned int db_index, LayoutToNetlist ptr db)

Description: Replaces the netlist database with the given index

Returns: The index of the database within the view (see lvsdb)

If the index is not valid, the database will be added to the view (see add_lvsdb).

This method has been added in version 0.26.

replace_layer_node

(1) Signature: void **replace_layer_node** (const LayerPropertiesIterator iter, const LayerProperties node)

Description: Replaces the layer node at the position given by "iter" with a new one

Since version 0.22, this method accepts LayerProperties and LayerPropertiesNode objects. A LayerPropertiesNode object can contain a hierarchy of further nodes.

(2) Signature: void **replace_layer_node** (unsigned int index, const LayerPropertiesIterator iter, const LayerProperties node)

Description: Replaces the layer node at the position given by "iter" with a new one

This version addresses a specific list in a multi-tab layer properties arrangement with the "index" parameter. This method has been introduced in version 0.21. Since version 0.22, this method accepts LayerProperties and LayerPropertiesNode objects. A LayerPropertiesNode object can contain a hierarchy of further nodes.

replace_lvsdb

Signature: unsigned int **replace_lvsdb** (unsigned int db_index, LayoutVsSchematic ptr db)

Description: Replaces the database with the given index

Returns: The index of the database within the view (see lvsdb)

If the index is not valid, the database will be added to the view (see add_lvsdb).

This method has been added in version 0.26.

replace_rdb

Signature: unsigned int **replace_rdb** (unsigned int db_index, ReportDatabase ptr db)

Description: Replaces the report database with the given index

Returns: The index of the database within the view (see rdb)

If the index is not valid, the database will be added to the view (see add_rdb).

This method has been added in version 0.26.

reset_title

Signature: void **reset_title**

Description: Resets the title to the standard title

See set_title and title for a description about how titles are handled.

resize

Signature: void **resize** (unsigned int w, unsigned int h)

Description: Resizes the layout view to the given dimension

This method has been made available in all builds in 0.28.

save_as

(1) Signature: void **save_as** (unsigned int index, string filename, bool gzip, const SaveLayoutOptions options)

Description: Saves a layout to the given stream file

index:	The cellview index of the layout to save.
filename:	The file to write.
gzip:	Ignored.
options:	Writer options.

Use of this method is deprecated

The layout with the given index is written to the stream file with the given options. 'options' is a SaveLayoutOptions object that specifies which format to write and further options such as scaling factor etc. Calling this method is equivalent to calling 'write' on the respective layout object.

This method is deprecated starting from version 0.23. The compression mode is determined from the file name automatically and the gzip parameter is ignored.

(2) Signature: void **save_as** (unsigned int index, string filename, const SaveLayoutOptions options)

Description: Saves a layout to the given stream file

index:	The cellview index of the layout to save.
filename:	The file to write.
options:	Writer options.

The layout with the given index is written to the stream file with the given options. 'options' is a SaveLayoutOptions object that specifies which format to write and further options such as scaling factor etc. Calling this method is equivalent to calling 'write' on the respective layout object.

If the file name ends with a suffix ".gz" or ".gzip", the file is compressed with the zlib algorithm.

save_image

Signature: void **save_image** (string filename, unsigned int width, unsigned int height)

Description: Saves the layout as an image to the given file

filename:	The file to which to write the screenshot to.
width:	The width of the image to render in pixel.
height:	The height of the image to render in pixel.

The image contains the current scene (layout, annotations etc.). The image is written as a PNG file to the given file. The image is drawn synchronously with the given width and height. Drawing may take some time.

save_image_with_options

Signature: void **save_image_with_options** (string filename, unsigned int width, unsigned int height, int linewidth = 0, int oversampling = 0, double resolution = 0, const DBox target = current, bool monochrome = false)

Description: Saves the layout as an image to the given file (with options)

filename:	The file to which to write the screenshot to.
width:	The width of the image to render in pixel.
height:	The height of the image to render in pixel.
linewidth:	The line width scale factor (usually 1) or 0 for 1/resolution.
oversampling:	The oversampling factor (1..3) or 0 for the oversampling the view was configured with.
resolution:	The resolution (pixel size compared to a screen pixel) or 0 for 1/oversampling.
target_box:	The box to draw or an empty box for default.
monochrome:	If true, monochrome images will be produced.

The image contains the current scene (layout, annotations etc.). The image is written as a PNG file to the given file. The image is drawn synchronously with the given width and height. Drawing may take some time. Monochrome images don't have background or annotation objects currently.

The 'linewidth' factor scales the layout style line widths.

The 'oversampling' factor will use multiple passes passes to create a single image pixels. An oversampling factor of 2 uses 2x2 virtual pixels to generate an output pixel. This results in a smoother image. This however comes with a corresponding memory and run time penalty. When using oversampling, you can set linewidth and resolution to 0. This way, line widths and stipple pattern are scaled such that the resulting image is equivalent to the standard image.

The 'resolution' is the pixel size used to translate font sizes and stipple pattern. A resolution of 0.5 renders twice as large fonts and stipple pattern. When combining this value with an oversampling factor of 2 and a line width factor of 2, the resulting image is an oversampled version of the standard image.

Examples:

```
# standard image 500x500 pixels (oversampling as configured in the view)
layout_view.save_image_with_options("image.png", 500, 500)

# 2x oversampled image with 500x500 pixels
layout_view.save_image_with_options("image.png", 500, 500, 0, 2, 0)

# 2x scaled image with 1000x1000 pixels
layout_view.save_image_with_options("image.png", 1000, 1000, 2, 1, 0.5)
```

This method has been introduced in 0.23.10.

save_layer_props

Signature: void **save_layer_props** (string fn)

Description: Saves the layer properties

Save the layer properties to the file given in "fn"

save_screenshot

Signature: void **save_screenshot** (string filename)

Description: Saves a screenshot to the given file

filename: The file to which to write the screenshot to.

The screenshot is written as a PNG file to the given file. This requires the drawing to be complete. Ideally, synchronous mode is switched on for the application to guarantee this condition. The image will have the size of the viewport showing the current layout.

select_all

Signature: void **select_all**

Description: Selects all objects from the view

This method has been introduced in version 0.27

select_cell

Signature: void **select_cell** (unsigned int cell_index, int cv_index)

Description: Selects a cell by index for a certain cell view

Use of this method is deprecated

Select the current (top) cell by specifying a path (a list of cell indices from top to the actual cell) and the cellview index for which this cell should become the currently shown one. This method selects the cell to be drawn. In constrast, the set_current_cell_path method selects the cell that is

	highlighted in the cell tree (but not necessarily drawn). This method is was deprecated in version 0.25 since from then, the CellView object can be used to obtain an manipulate the selected cell.
select_cell_path	**Signature**: void **select_cell_path** (unsigned int[] cell_index, int cv_index) **Description**: Selects a cell by cell index for a certain cell view Use of this method is deprecated Select the current (top) cell by specifying a cell indexand the cellview index for which this cell should become the currently shown one. The path to the cell is constructed by selecting one that leads to a top cell. This method selects the cell to be drawn. In constrast, the set_current_cell_path method selects the cell that is highlighted in the cell tree (but not necessarily drawn). This method is was deprecated in version 0.25 since from then, the CellView object can be used to obtain an manipulate the selected cell.
select_from	**(1) Signature**: void **select_from** (const DPoint point, LayoutView::SelectionMode mode = Replace) **Description**: Selects the objects from a given point The mode indicates whether to add to the selection, replace the selection, remove from selection or invert the selected status of the objects found around the given point. This method has been introduced in version 0.27 **(2) Signature**: void **select_from** (const DBox box, LayoutView::SelectionMode mode = Replace) **Description**: Selects the objects from a given box The mode indicates whether to add to the selection, replace the selection, remove from selection or invert the selected status of the objects found inside the given box. This method has been introduced in version 0.27
select_object	**Signature**: *[const]* void **select_object** (const ObjectInstPath obj) **Description**: Adds the given selection to the list of selected objects The selection provided by the ObjectInstPath descriptor is added to the list of selected objects. To clear the previous selection, use clear_object_selection. The selection of other objects (such as annotations and images) will not be affected. Another way of selecting objects is object_selection=. This method has been introduced in version 0.24
selected_cells_paths	**Signature**: *[const]* unsigned int[][] **selected_cells_paths** (int cv_index) **Description**: Gets the paths of the selected cells Gets a list of cell paths to the cells selected in the cellview given by cv_index. The "selected cells" are the ones selected in the cell list or cell tree. This is not the "current cell" which is the one that is shown in the layout window. The cell paths are arrays of cell indexes where the last element is the actual cell selected. This method has be introduced in version 0.25.
selected_layers	**Signature**: *[const]* LayerPropertiesIterator[] **selected_layers** **Description**: Gets the selected layers

	Returns an array of LayerPropertiesIterator objects pointing to the currently selected layers. If no layer view is selected currently, an empty array is returned.
selection_bbox	**Signature**: DBox **selection_bbox** **Description**: Returns the bounding box of the current selection This method has been introduced in version 0.26.2
selection_size	**Signature**: unsigned long **selection_size** **Description**: Returns the number of selected objects This method has been introduced in version 0.27
send_enter_event	**Signature**: void **send_enter_event** **Description**: Sends a mouse window leave event This method is intended to emulate the mouse mouse window leave events sent by Qt normally in environments where Qt is not present. This method was introduced in version 0.28.
send_key_press_event	**Signature**: void **send_key_press_event** (unsigned int key, unsigned int buttons) **Description**: Sends a key press event This method is intended to emulate the key press events sent by Qt normally in environments where Qt is not present. The arguments follow the conventions used within Plugin#key_event for example. This method was introduced in version 0.28.
send_leave_event	**Signature**: void **send_leave_event** **Description**: Sends a mouse window leave event This method is intended to emulate the mouse mouse window leave events sent by Qt normally in environments where Qt is not present. This method was introduced in version 0.28.
send_mouse_double_clicked_event	**Signature**: void **send_mouse_double_clicked_event** (const DPoint pt, unsigned int buttons) **Description**: Sends a mouse button double-click event This method is intended to emulate the mouse button double-click events sent by Qt normally in environments where Qt is not present. The arguments follow the conventions used within Plugin#mouse_moved_event for example. This method was introduced in version 0.28.
send_mouse_move_event	**Signature**: void **send_mouse_move_event** (const DPoint pt, unsigned int buttons) **Description**: Sends a mouse move event This method is intended to emulate the mouse move events sent by Qt normally in environments where Qt is not present. The arguments follow the conventions used within Plugin#mouse_moved_event for example. This method was introduced in version 0.28.
send_mouse_press_event	**Signature**: void **send_mouse_press_event** (const DPoint pt, unsigned int buttons) **Description**: Sends a mouse button press event

This method is intended to emulate the mouse button press events sent by Qt normally in environments where Qt is not present. The arguments follow the conventions used within Plugin#mouse_moved_event for example.

This method was introduced in version 0.28.

send_mouse_release_event

Signature: void **send_mouse_release_event** (const DPoint pt, unsigned int buttons)

Description: Sends a mouse button release event

This method is intended to emulate the mouse button release events sent by Qt normally in environments where Qt is not present. The arguments follow the conventions used within Plugin#mouse_moved_event for example.

This method was introduced in version 0.28.

send_wheel_event

Signature: void **send_wheel_event** (int delta, bool horizontal, const DPoint pt, unsigned int buttons)

Description: Sends a mouse wheel event

This method is intended to emulate the mouse wheel events sent by Qt normally in environments where Qt is not present. The arguments follow the conventions used within Plugin#wheel_event for example.

This method was introduced in version 0.28.

set_active_cellview_index

Signature: void **set_active_cellview_index** (int index)

Description: Makes the cellview with the given index the active one (shown in hierarchy browser)

Use of this method is deprecated. Use active_setview_index= instead

See active_cellview_index.

This method has been renamed from set_active_cellview_index to active_cellview_index= in version 0.25. The original name is still available, but is deprecated.

Python specific notes:
The object exposes a writable attribute 'active_setview_index'. This is the setter.

set_config

Signature: void **set_config** (string name, string value)

Description: Sets a local configuration parameter with the given name to the given value

name:	The name of the configuration parameter to set
value:	The value to which to set the configuration parameter

This method sets a local configuration parameter with the given name to the given value. Values can only be strings. Numerical values have to be converted into strings first. Local configuration parameters override global configurations for this specific view. This allows for example to override global settings of background colors. Any local settings are not written to the configuration file.

set_current_cell_path

Signature: void **set_current_cell_path** (int cv_index, unsigned int[] cell_path)

Description: Sets the path to the current cell

cv_index:	The cellview index for which to set the current path for (usually this will be the active cellview index)
path:	The path to the current cell

Use of this method is deprecated

The current cell is the one highlighted in the browser with the focus rectangle. The cell given by the path is highlighted and scrolled into view. To select the cell to be drawn, use the select_cell or select_cell_path method.

This method is was deprecated in version 0.25 since from then, the CellView object can be used to obtain an manipulate the selected cell.

set_current_layer_list

Signature: void **set_current_layer_list** (unsigned int index)

Description: Sets the index of the currently selected layer properties tab

Use of this method is deprecated. Use current_layer_list= instead

This method has been introduced in version 0.21.

Python specific notes:
The object exposes a writable attribute 'current_layer_list'. This is the setter.

set_layer_properties

(1) Signature: void **set_layer_properties** (const LayerPropertiesIterator iter, const LayerProperties props)

Description: Sets the layer properties of the layer pointed to by the iterator

This method replaces the layer properties of the element pointed to by "iter" by the properties given by "props". It will not change the hierarchy but just the properties of the given node.

(2) Signature: void **set_layer_properties** (unsigned int index, const LayerPropertiesIterator iter, const LayerProperties props)

Description: Sets the layer properties of the layer pointed to by the iterator

This method replaces the layer properties of the element pointed to by "iter" by the properties given by "props" in the tab given by "index". It will not change the hierarchy but just the properties of the given node.This version addresses a specific list in a multi-tab layer properties arrangement with the "index" parameter. This method has been introduced in version 0.21.

set_title

Signature: void **set_title** (string title)

Description: Sets the title of the view

title: The title string to use

Use of this method is deprecated. Use title= instead

Override the standard title of the view indicating the file names loaded by the specified title string. The title string can be reset with reset_title to the standard title again.

Python specific notes:
The object exposes a writable attribute 'title'. This is the setter.

show_all_cells

(1) Signature: void **show_all_cells**

Description: Makes all cells shown (cancel effects of hide_cell)

(2) Signature: void **show_all_cells** (int cv_index)

Description: Makes all cells shown (cancel effects of hide_cell) for the specified cell view

Unlike show_all_cells, this method will only clear the hidden flag on the cell view selected by cv_index.

This variant has been added in version 0.25.

show_cell

Signature: void **show_cell** (unsigned int cell_index, int cv_index)

Description: Shows the given cell for the given cellview (cancel effect of hide_cell)

show_image

Signature: void **show_image** (unsigned long id, bool visible)

Description: Shows or hides the given image

id: The id of the object to show or hide

visible: True, if the image should be shown

Sets the visibility of the image with the given Id. The Id can be obtained with if "id" method of the image object.

This method has been introduced in version 0.20.

With version 0.25, Image#visible= can be used to achieve the same results.

show_l2ndb

Signature: void **show_l2ndb** (int l2ndb_index, int cv_index)

Description: Shows a netlist database in the marker browser on a certain layout

The netlist browser is opened showing the netlist database with the index given by "l2ndb_index". It will be attached (i.e. navigate to) the layout with the given cellview index in "cv_index".

This method has been added in version 0.26.

show_layout

(1) Signature: unsigned int **show_layout** (Layout ptr layout, bool add_cellview)

Description: Shows an existing layout in the view

Returns: The index of the cellview created.

Shows the given layout in the view. If add_cellview is true, the new layout is added to the list of cellviews in the view.

Note: once a layout is passed to the view with show_layout, it is owned by the view and must not be destroyed with the 'destroy' method.

This method has been introduced in version 0.22.

(2) Signature: unsigned int **show_layout** (Layout ptr layout, string tech, bool add_cellview)

Description: Shows an existing layout in the view

Returns: The index of the cellview created.

Shows the given layout in the view. If add_cellview is true, the new layout is added to the list of cellviews in the view. The technology to use for that layout can be specified as well with the 'tech' parameter. Depending on the definition of the technology, layer properties may be loaded for example. The technology string can be empty for the default technology.

Note: once a layout is passed to the view with show_layout, it is owned by the view and must not be destroyed with the 'destroy' method.

This method has been introduced in version 0.22.

(3) Signature: unsigned int **show_layout** (Layout ptr layout, string tech, bool add_cellview, bool init_layers)

Description: Shows an existing layout in the view

Returns: The index of the cellview created.

Shows the given layout in the view. If add_cellview is true, the new layout is added to the list of cellviews in the view. The technology to use for that layout can be specified as well with the 'tech' parameter. Depending on the definition of the technology, layer properties may be loaded for example. The technology string can be empty for the default technology. This variant also allows one to control whether the layer properties are initialized (init_layers = true) or not (init_layers = false).

Note: once a layout is passed to the view with show_layout, it is owned by the view and must not be destroyed with the 'destroy' method.

This method has been introduced in version 0.22.

show_lvsdb

Signature: void **show_lvsdb** (int lvsdb_index, int cv_index)

Description: Shows a netlist database in the marker browser on a certain layout

The netlist browser is opened showing the netlist database with the index given by "lvsdb_index". It will be attached (i.e. navigate to) the layout with the given cellview index in "cv_index".

This method has been added in version 0.26.

show_rdb

Signature: void **show_rdb** (int rdb_index, int cv_index)

Description: Shows a report database in the marker browser on a certain layout

The marker browser is opened showing the report database with the index given by "rdb_index". It will be attached (i.e. navigate to) the layout with the given cellview index in "cv_index".

stop

Signature: void **stop**

Description: Stops redraw thread and close any browsers

This method usually does not need to be called explicitly. The redraw thread is stopped automatically.

stop_redraw

Signature: void **stop_redraw**

Description: Stops the redraw thread

It is very important to stop the redraw thread before applying changes to the layout or the cell views and the LayoutView configuration. This is usually done automatically. For rare cases, where this is not the case, this method is provided.

switch_mode

Signature: void **switch_mode** (string mode)

Description: Switches the mode.

See mode_name about a method to get the name of the current mode and mode_names for a method to retrieve all available mode names.

This method has been introduced in version 0.28.

title

Signature: *[const]* string **title**

Description: Returns the view's title string

Returns: The title string

The title string is either a string composed of the file names loaded (in some "readable" manner) or a customized title string set by set_title.

Python specific notes:
The object exposes a readable attribute 'title'. This is the getter.

title=

Signature: void **title=** (string title)

Description: Sets the title of the view

title: The title string to use

Override the standard title of the view indicating the file names loaded by the specified title string. The title string can be reset with reset_title to the standard title again.

Python specific notes:

The object exposes a writable attribute 'title'. This is the setter.

transaction

Signature: void **transaction** (string description)

Description: Begins a transaction

description: A text that appears in the 'undo' description

A transaction brackets a sequence of database modifications that appear as a single undo action. Only modifications that are wrapped inside a transaction..commit call pair can be undone. Each transaction must be terminated with a commit method call, even if some error occurred. It is advisable therefore to catch errors and issue a commit call in this case.

This method was introduced in version 0.16.

transient_to_selection

Signature: void **transient_to_selection**

Description: Turns the transient selection into the actual selection

The current selection is cleared before. All highlighted objects under the mouse will become selected. This applies to all types of objects (rulers, shapes, images ...).

This method has been introduced in version 0.26.2

unregister_annotation_templ

Signature: void **unregister_annotation_templates** (string category)

Description: Unregisters the template or templates with the given category string on this particular view

See Annotation#unregister_templates for a method doing the same on application level.This method is hardly useful normally, but can be used when customizing layout views as individual widgets.

This method has been added in version 0.28.

unselect_object

Signature: *[const]* void **unselect_object** (const ObjectInstPath obj)

Description: Removes the given selection from the list of selected objects

The selection provided by the ObjectInstPath descriptor is removed from the list of selected objects. If the given object was not part of the selection, nothing will be changed. The selection of other objects (such as annotations and images) will not be affected.

This method has been introduced in version 0.24

update_content

Signature: void **update_content**

Description: Updates the layout view to the current state

This method triggers an update of the hierarchy tree and layer view tree. Usually, this method does not need to be called. The widgets are updated automatically in most cases.

Currently, this method should be called however, after the layer view tree has been changed by the insert_layer, replace_layer_node or delete_layer methods.

viewport_height

Signature: *[const]* int **viewport_height**

Description: Return the viewport height in pixels

This method was introduced in version 0.18.

viewport_trans

Signature: *[const]* DCplxTrans **viewport_trans**

Description: Returns the transformation that converts micron coordinates to pixels

	Hint: the transformation returned will convert any point in micron coordinate space into a pixel coordinate. Contrary to usual convention, the y pixel coordinate is given in a mathematically oriented space - which means the bottom coordinate is 0. This method was introduced in version 0.18.
viewport_width	**Signature**: *[const]* int **viewport_width** **Description**: Returns the viewport width in pixels This method was introduced in version 0.18.
widget	**Signature**: QWidget ptr **widget** **Description**: Gets the QWidget object of the view This method has been introduced in version 0.28.7.
zoom_box	**Signature**: void **zoom_box** (const DBox box) **Description**: Sets the viewport to the given box **box**: The box to which to set the view in micron coordinates
zoom_fit	**Signature**: void **zoom_fit** **Description**: Fits the contents of the current view into the window
zoom_fit_sel	**Signature**: void **zoom_fit_sel** **Description**: Fits the contents of the current selection into the window This method has been introduced in version 0.25.
zoom_in	**Signature**: void **zoom_in** **Description**: Zooms in somewhat
zoom_out	**Signature**: void **zoom_out** **Description**: Zooms out somewhat

4.221. API reference - Class ObjectInstPath

Notation used in Ruby API documentation

Module: lay

Description: A class describing a selected shape or instance

A shape or instance is addressed by a path which describes all instances leading to the specified object. These instances are described through InstElement objects, which specify the instance and, in case of array instances, the specific array member. For shapes, additionally the layer and the shape itself is specified. The ObjectInstPath objects encapsulates both forms, which can be distinguished with the is_cell_inst? predicate.

An instantiation path leads from a top cell down to the container cell which either holds the shape or the instance. The top cell can be obtained through the top attribute, the container cell through the source attribute. Both are cell indexes which can be converted to Cell objects through the Layout#cell. In case of objects located in the top cell, top and source refer to the same cell. The first element of the instantiation path is the instance located within the top cell leading to the first child cell. The second element leads to the next child cell and so forth. path_nth can be used to obtain a specific element of the path.

The cv_index attribute specifies the cellview the selection applies to. Use LayoutView#cellview to obtain the CellView object from the index.

The shape or instance the selection refers to can be obtained with shape and inst respectively. Use is_cell_inst? to decide whether the selection refers to an instance or not.

The ObjectInstPath class plays a role when retrieving and modifying the selection of shapes and instances through LayoutView#object_selection, LayoutView#object_selection=, LayoutView#select_object and LayoutView#unselect_object. ObjectInstPath objects can be modified to reflect a new selection, but the new selection becomes active only after it is installed in the view. The following sample demonstrates that. It implements a function to convert all shapes to polygons:

```
mw = RBA::Application::instance::main_window
view = mw.current_view

begin

  view.transaction("Convert selected shapes to polygons")

  sel = view.object_selection

  sel.each do |s|
    if !s.is_cell_inst? && !s.shape.is_text?
      ly = view.cellview(s.cv_index).layout
      # convert to polygon
      s.shape.polygon = s.shape.polygon
    end
  end

  view.object_selection = sel

ensure
  view.commit
end
```

Note, that without resetting the selection in the above example, the application might raise errors because after modifying the selected objects, the current selection will no longer be valid. Establishing a new valid selection in the way shown above will help avoiding this issue.

Public constructors

new ObjectInstPath ptr	**new**	(const RecursiveShapeIterator si, int cv_index)	Creates a new path object from a RecursiveShapeIterator

Public methods

[const]	bool	**!=**	(const ObjectInstPath b)	Inequality of two ObjectInstPath objects
[const]	bool	**<**	(const ObjectInstPath b)	Provides an order criterion for two ObjectInstPath objects
[const]	bool	**==**	(const ObjectInstPath b)	Equality of two ObjectInstPath objects
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**append_path**	(const InstElement element)	Appends an element to the instantiation path
	void	**assign**	(const ObjectInstPath other)	Assigns another object to self
[const]	unsigned int	**cell_index**		Gets the cell index of the cell that the selection applies to.
	void	**clear_path**		Clears the instantiation path
[const]	unsigned int	**cv_index**		Gets the cellview index that describes which cell view the shape or instance is located in
	void	**cv_index=**	(unsigned int index)	Sets the cellview index that describes which cell view the shape or instance is located in
[const]	DCplxTrans	**dtrans**		Gets the transformation applicable for the shape in micron space.
[const]	new ObjectInstPath ptr	**dup**		Creates a copy of self
[const,iter]	InstElement	**each_inst**		Yields the instantiation path
[const]	Instance	**inst**		Deliver the instance represented by this selection

[const]	bool	**is_cell_inst?**		True, if this selection represents a cell instance
[const]	bool	**is_valid?**	(LayoutView ptr view)	Gets a value indicating whether the instance path refers to a valid object in the context of the given view
[const]	variant	**layer**		Gets the layer index that describes which layer the selected shape is on
	void	**layer=**	(unsigned int layer_index)	Sets to the layer index that describes which layer the selected shape is on
[const]	Layout ptr	**layout**		Gets the Layout object the selected object lives in.
[const]	InstElement[]	**path**		Gets the instantiation path
	void	**path=**	(InstElement[] p)	Sets the instantiation path
[const]	unsigned int	**path_length**		Returns the length of the path (number of elements delivered by each_inst)
[const]	InstElement	**path_nth**	(unsigned int n)	Returns the nth element of the path (similar to each_inst but with direct access through the index)
[const]	unsigned long	**seq**		Gets the sequence number
	void	**seq=**	(unsigned long n)	Sets the sequence number
[const]	variant	**shape**		Gets the selected shape
	void	**shape=**	(const Shape shape)	Sets the shape object that describes the selected shape geometrically
[const]	unsigned int	**source**		Returns to the cell index of the cell that the selected element resides inside.
[const]	DCplxTrans	**source_dtrans**		Gets the transformation applicable for an instance and shape in micron space.
[const]	ICplxTrans	**source_trans**		Gets the transformation applicable for an instance and shape.
[const]	unsigned int	**top**		Gets the cell index of the top cell the selection applies to
	void	**top=**	(unsigned int cell_index)	Sets the cell index of the top cell the selection applies to
[const]	ICplxTrans	**trans**		Gets the transformation applicable for the shape.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead

	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

!=

Signature: *[const]* bool **!=** (const ObjectInstPath b)

Description: Inequality of two ObjectInstPath objects

See the comments on the == operator.

This method has been introduced with version 0.24.

<

Signature: *[const]* bool **<** (const ObjectInstPath b)

Description: Provides an order criterion for two ObjectInstPath objects

Note: this operator is just provided to establish any order, not a particular one.

This method has been introduced with version 0.24.

==

Signature: *[const]* bool **==** (const ObjectInstPath b)

Description: Equality of two ObjectInstPath objects

Note: this operator returns true if both instance paths refer to the same object, not just identical ones.

This method has been introduced with version 0.24.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

append_path

Signature: void **append_path** (const InstElement element)

Description: Appends an element to the instantiation path

This method allows building of an instantiation path pointing to the selected object. For an instance selection, the last component added is the instance which is selected. For a shape selection, the path points to the cell containing the selected shape.

This method was introduced in version 0.24.

assign

Signature: void **assign** (const ObjectInstPath other)

Description: Assigns another object to self

cell_index

Signature: *[const]* unsigned int **cell_index**

Description: Gets the cell index of the cell that the selection applies to.

This method returns the cell index that describes which cell the selected shape is located in or the cell whose instance is selected if is_cell_inst? is true. This property is set implicitly by setting the top cell and adding elements to the instantiation path. To obtain the index of the container cell, use source.

clear_path

Signature: void **clear_path**

Description: Clears the instantiation path

This method was introduced in version 0.24.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

cv_index

Signature: *[const]* unsigned int **cv_index**

Description: Gets the cellview index that describes which cell view the shape or instance is located in

Python specific notes:
The object exposes a readable attribute 'cv_index'. This is the getter.

cv_index=

Signature: void **cv_index=** (unsigned int index)

Description: Sets the cellview index that describes which cell view the shape or instance is located in

This method has been introduced in version 0.24.

Python specific notes:
The object exposes a writable attribute 'cv_index'. This is the setter.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dtrans

Signature: *[const]* DCplxTrans **dtrans**

Description: Gets the transformation applicable for the shape in micron space.

This method returns the same transformation than trans, but applicable to objects in micrometer units:

```
# renders the micrometer-unit polygon in top cell coordinates:
dpolygon_in_top = sel.dtrans * sel.shape.dpolygon
```

This method is not applicable to instance selections. A more generic attribute is source_dtrans.

The method has been introduced in version 0.25.

dup

Signature: *[const]* new ObjectInstPath ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

each_inst

Signature: *[const,iter]* InstElement **each_inst**

Description: Yields the instantiation path

The instantiation path describes by an sequence of InstElement objects the path by which the cell containing the selected shape is found from the cell view's current cell. If this object represents an instance, the path will contain the selected instance as the last element. The elements are delivered top down.

inst

Signature: *[const]* Instance **inst**

Description: Deliver the instance represented by this selection

This method delivers valid results only if is_cell_inst? is true. It returns the instance reference (an Instance object) that this selection represents.

This property is set implicitly by adding instance elements to the instantiation path.

This method has been added in version 0.16.

is_cell_inst?

Signature: *[const]* bool **is_cell_inst?**

Description: True, if this selection represents a cell instance

If this attribute is true, the shape reference and layer are not valid.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_valid?

Signature: *[const]* bool **is_valid?** (LayoutView ptr view)

Description: Gets a value indicating whether the instance path refers to a valid object in the context of the given view

This predicate has been introduced in version 0.27.12.

layer

Signature: *[const]* variant **layer**

Description: Gets the layer index that describes which layer the selected shape is on

Starting with version 0.27, this method returns nil for this property if is_cell_inst? is false - i.e. the selection does not represent a shape.

Python specific notes:
The object exposes a readable attribute 'layer'. This is the getter.

layer=

Signature: void **layer=** (unsigned int layer_index)

Description: Sets to the layer index that describes which layer the selected shape is on

Setting the layer property to a valid layer index makes the path a shape selection path. Setting the layer property to a negative layer index makes the selection an instance selection.

This method has been introduced in version 0.24.

Python specific notes:
The object exposes a writable attribute 'layer'. This is the setter.

layout

Signature: *[const]* Layout ptr **layout**

Description: Gets the Layout object the selected object lives in.

This method returns the Layout object that the selected object lives in. This method may return nil, if the selection does not point to a valid object.

This method has been introduced in version 0.25.

new

Signature: *[static]* new ObjectInstPath ptr **new** (const RecursiveShapeIterator si, int cv_index)

Description: Creates a new path object from a RecursiveShapeIterator

Use this constructor to quickly turn a recursive shape iterator delivery into a shape selection.

Python specific notes:
This method is the default initializer of the object.

path

Signature: *[const]* InstElement[] **path**

Description: Gets the instantiation path

The path is a sequence of InstElement objects leading to the target object.

This method was introduced in version 0.26.

Python specific notes:
The object exposes a readable attribute 'path'. This is the getter.

path=

Signature: void **path=** (InstElement[] p)

Description: Sets the instantiation path

This method was introduced in version 0.26.

Python specific notes:
The object exposes a writable attribute 'path'. This is the setter.

path_length

Signature: *[const]* unsigned int **path_length**

Description: Returns the length of the path (number of elements delivered by each_inst)

This method has been added in version 0.16.

path_nth

Signature: *[const]* InstElement **path_nth** (unsigned int n)

Description: Returns the nth element of the path (similar to each_inst but with direct access through the index)

n: The index of the element to retrieve (0..path_length-1)

This method has been added in version 0.16.

seq

Signature: *[const]* unsigned long **seq**

Description: Gets the sequence number

The sequence number describes when the item was selected. A sequence number of 0 indicates that the item was selected in the first selection action (without 'Shift' pressed).

Python specific notes:
The object exposes a readable attribute 'seq'. This is the getter.

seq=

Signature: void **seq=** (unsigned long n)

Description: Sets the sequence number

See seq for a description of this property.

This method was introduced in version 0.24.

Python specific notes:
The object exposes a writable attribute 'seq'. This is the setter.

shape

Signature: *[const]* variant **shape**

Description: Gets the selected shape

The shape object may be modified. This does not have an immediate effect on the selection. Instead, the selection must be set in the view using LayoutView#object_selection= or LayoutView#select_object.

This method delivers valid results only for object selections that represent shapes. Starting with version 0.27, this method returns nil for this property if is_cell_inst? is false.

Python specific notes:
The object exposes a readable attribute 'shape'. This is the getter.

shape=

Signature: void **shape=** (const Shape shape)

Description: Sets the shape object that describes the selected shape geometrically

When using this setter, the layer index must be set to a valid layout layer (see layer=). Setting both properties makes the selection a shape selection.

This method has been introduced in version 0.24.

Python specific notes:
The object exposes a writable attribute 'shape'. This is the setter.

source

Signature: *[const]* unsigned int **source**

Description: Returns to the cell index of the cell that the selected element resides inside.

If this reference represents a cell instance, this method delivers the index of the cell in which the cell instance resides. Otherwise, this method returns the same value than cell_index.

This property is set implicitly by setting the top cell and adding elements to the instantiation path.

This method has been added in version 0.16.

source_dtrans

Signature: *[const]* DCplxTrans **source_dtrans**

Description: Gets the transformation applicable for an instance and shape in micron space.

This method returns the same transformation than source_trans, but applicable to objects in micrometer units:

```
# renders the cell instance as seen from top level:
dcell_inst_in_top = sel.source_dtrans * sel.inst.dcell_inst
```

The method has been introduced in version 0.25.

source_trans

Signature: *[const]* ICplxTrans **source_trans**

Description: Gets the transformation applicable for an instance and shape.

If this object represents a shape, this transformation describes how the selected shape is transformed into the current cell of the cell view. If this object represents an instance, this transformation describes how the selected instance is transformed into the current cell of the cell view. This method is similar to trans, except that the resulting transformation does not include the instance transformation if the object represents an instance.

This property is set implicitly by setting the top cell and adding elements to the instantiation path.

This method has been added in version 0.16.

top

Signature: *[const]* unsigned int **top**

Description: Gets the cell index of the top cell the selection applies to

	The top cell is identical to the current cell provided by the cell view. It is the cell from which is instantiation path originates and the container cell if not instantiation path is set. This method has been introduced in version 0.24. **Python specific notes:** The object exposes a readable attribute 'top'. This is the getter.
top=	**Signature**: void **top=** (unsigned int cell_index) **Description**: Sets the cell index of the top cell the selection applies to See top_cell for a description of this property. This method has been introduced in version 0.24. **Python specific notes:** The object exposes a writable attribute 'top'. This is the setter.
trans	**Signature**: *[const]* ICplxTrans **trans** **Description**: Gets the transformation applicable for the shape. If this object represents a shape, this transformation describes how the selected shape is transformed into the current cell of the cell view. Basically, this transformation is the accumulated transformation over the instantiation path. If the ObjectInstPath represents a cell instance, this includes the transformation of the selected instance as well. This property is set implicitly by setting the top cell and adding elements to the instantiation path. This method is not applicable for instance selections. A more generic attribute is source_trans.

4.222. API reference - Class MacroExecutionContext

Notation used in Ruby API documentation

Module: lay

Description: Support for various debugger features

This class implements some features that allow customization of the debugger behavior, specifically the generation of back traces and the handling of exception. These functions are particular useful for implementing DSL interpreters and providing proper error locations in the back traces or to suppress exceptions when re-raising them.

Public constructors

new MacroExecutionContext ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const MacroExec other)	Assigns another object to self
[const]	new MacroExecutionContext ptr	**dup**		Creates a copy of self

Public static methods and constants

void	**ignore_next_exception**		Ignores the next exception in the debugger
void	**remove_debugger_scope**		Removes a debugger scope previously set with set_debugger_scope
void	**set_debugger_scope**	(string filename)	Sets a debugger scope (file level which shall appear in the debugger)

Deprecated methods (protected, public, static, non-static and constructors)

void	**create**		Use of this method is deprecated. Use _create instead
void	**destroy**		Use of this method is deprecated. Use _destroy instead

[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const MacroExecutionContext other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new MacroExecutionContext ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

ignore_next_exception

Signature: *[static]* void **ignore_next_exception**

Description: Ignores the next exception in the debugger

The next exception thrown will be ignored in the debugger. That feature is useful when re-raising exceptions if those new exception shall not appear in the debugger.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new MacroExecutionContext ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

remove_debugger_scope

Signature: *[static]* void **remove_debugger_scope**

Description: Removes a debugger scope previously set with set_debugger_scope

set_debugger_scope

Signature: *[static]* void **set_debugger_scope** (string filename)

Description: Sets a debugger scope (file level which shall appear in the debugger)

If a debugger scope is set, back traces will be produced starting from that scope. Setting a scope is useful for implementing DSL interpreters and giving a proper hint about the original location of an error.

4.223. API reference - Class MacroInterpreter

Notation used in Ruby API documentation

Module: lay

Description: A custom interpreter for a DSL (domain specific language)

DSL interpreters are a way to provide macros written in a language specific for the application. One example are DRC scripts which are written in some special language optimized for DRC ruledecks. Interpreters for such languages can be built using scripts itself by providing the interpreter implementation through this object.

An interpreter implementation involves at least these steps:

- Derive a new object from RBA::MacroInterpreter
- Reimplement the execute method for the actual execution of the code
- In the initialize method configure the object using the attribute setters like suffix= and register the object as DSL interpreter (in that order)
- Create at least one template macro in the initialize method

Template macros provide a way for the macro editor to present macros for the new interpreter in the list of templates. Template macros can provide menu bindings, shortcuts and some initial text for example

The simple implementation can be enhanced by providing more information, i.e. syntax highlighter information, the debugger to use etc. This involves reimplementing further methods, i.e. "syntax_scheme".

This is a simple example for an interpreter in Ruby. Is is registered under the name 'simple-dsl' and just evaluates the script text:

```
class SimpleExecutable < RBA::Excutable

  # Constructor
  def initialize(macro)
    @macro = macro
  end

  # Implements the execute method
  def execute
    eval(@macro.text, nil, @macro.path)
    nil
  end

end

class SimpleInterpreter < RBA::MacroInterpreter

  # Constructor
  def initialize
    self.description = "A test interpreter"
    # Registers the new interpreter
    register("simple-dsl")
    # create a template for the macro editor:
    # Name is "new_simple", the description will be "Simple interpreter macro"
    # in the "Special" group.
    mt = create_template("new_simple")
    mt.description = "Special;;Simple interpreter macro"
  end

  # Creates the executable delegate
  def executable(macro)
    SimpleExecutable::new(macro)
  end

end
```

```
# Register the new interpreter
SimpleInterpreter::new
```

Please note that such an implementation is dangerous because the evaluation of the script happens in the context of the interpreter object. In this implementation the script could redefine the execute method for example. This implementation is provided as an example only. A real implementation should add execution of prolog and epilog code inside the execute method and proper error handling.

In order to make the above code effective, store the code in an macro, set "early auto-run" and restart KLayout.

This class has been introduced in version 0.23 and modified in 0.27.

Public constructors

new MacroInterpreter ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const MacroInterpreter other)	Assigns another object to self
	Macro ptr	**create_template**	(string url)	Creates a new macro template
	void	**debugger_scheme=**	(Macro::Interpreter scheme)	Sets the debugger scheme (which debugger to use for the DSL macro)
	void	**description=**	(string description)	Sets a description string
[const]	new MacroInterpreter ptr	**dup**		Creates a copy of self
[virtual,const]	Executable ptr	**executable**	(const Macro ptr macro)	Returns the executable object which implements the macro execution
	string[]	**include_expansion**	(Macro ptr macro)	Provides include expansion as defined by the interpreter
	void	**register**	(string name)	Registers the macro interpreter

void	storage_scheme=	(Macro::Format scheme)	Sets the storage scheme (the format as which the macro is stored)
void	suffix=	(string suffix)	Sets the file suffix
void	supports_include_expa	(bool flag)	Sets a value indicating whether this interpreter supports the default include file expansion scheme.
void	syntax_scheme=	(string scheme)	Sets a string indicating the syntax highlighter scheme

Public static methods and constants

[static,const]	Macro::Format	MacroFormat	The macro has macro (XML) format
	Macro::Interpreter	NoDebugger	Indicates no debugging for debugger_scheme
[static,const]	Macro::Format	PlainTextFormat	The macro has plain text format
[static,const]	Macro::Format	PlainTextWithHashAnnotationsFormat	The macro has plain text format with special pseudo-comment annotations
	Macro::Interpreter	RubyDebugger	Indicates Ruby debugger for debugger_scheme

Deprecated methods (protected, public, static, non-static and constructors)

	void	create	Use of this method is deprecated. Use _create instead
	void	destroy	Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	is_const_object?	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

MacroFormat

Signature: *[static,const]* Macro::Format **MacroFormat**

Description: The macro has macro (XML) format

Python specific notes:
The object exposes a readable attribute 'MacroFormat'. This is the getter.

NoDebugger

Signature: *[static]* Macro::Interpreter **NoDebugger**

Description: Indicates no debugging for debugger_scheme

Python specific notes:
The object exposes a readable attribute 'NoDebugger'. This is the getter.

PlainTextFormat

Signature: *[static,const]* Macro::Format **PlainTextFormat**

Description: The macro has plain text format

Python specific notes:
The object exposes a readable attribute 'PlainTextFormat'. This is the getter.

PlainTextWithHashAnnotationsFormat

Signature: *[static,const]* Macro::Format **PlainTextWithHashAnnotationsFormat**

Description: The macro has plain text format with special pseudo-comment annotations

Python specific notes:
The object exposes a readable attribute 'PlainTextWithHashAnnotationsFormat'. This is the getter.

RubyDebugger

Signature: *[static]* Macro::Interpreter **RubyDebugger**

Description: Indicates Ruby debugger for debugger_scheme

Python specific notes:
The object exposes a readable attribute 'RubyDebugger'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const MacroInterpreter other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

create_template

Signature: Macro ptr **create_template** (string url)

Description: Creates a new macro template

url: The template will be initialized from that URL.

This method will create a register a new macro template. It returns a Macro object which can be modified in order to adjust the template (for example to set description, add a content, menu binding, autorun flags etc.)

This method must be called after register has called.

debugger_scheme=

Signature: void **debugger_scheme=** (Macro::Interpreter scheme)

Description: Sets the debugger scheme (which debugger to use for the DSL macro)

The value can be one of the constants RubyDebugger or NoDebugger.

Use this attribute setter in the initializer before registering the interpreter.

Before version 0.25 this attribute was a re-implementable method. It has been turned into an attribute for performance reasons in version 0.25.

Python specific notes:
The object exposes a writable attribute 'debugger_scheme'. This is the setter.

description=

Signature: void **description=** (string description)

Description: Sets a description string

This string is used for showing the type of DSL macro in the file selection box together with the suffix for example. Use this attribute setter in the initializer before registering the interpreter.

Before version 0.25 this attribute was a re-implementable method. It has been turned into an attribute for performance reasons in version 0.25.

Python specific notes:
The object exposes a writable attribute 'description'. This is the setter.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new MacroInterpreter ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

executable

Signature: *[virtual,const]* Executable ptr **executable** (const Macro ptr macro)

Description: Returns the executable object which implements the macro execution

macro: The macro to execute

This method must be reimplemented to return an Executable object for the actual implementation. The system will use this function to execute the script when a macro with interpreter type 'dsl' and the name of this interpreter is run.

This method has been introduced in version 0.27 and replaces the 'execute' method.

include_expansion

Signature: string[] **include_expansion** (Macro ptr macro)

Description: Provides include expansion as defined by the interpreter

The return value will be a two-element array with the encoded file path and the include-expanded text.

This method has been introduced in version 0.28.12.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new MacroInterpreter ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

register

Signature: void **register** (string name)

Description: Registers the macro interpreter

name: The interpreter name. This is an arbitrary string which should be unique.

Registration of the interpreter makes the object known to the system. After registration, macros whose interpreter is set to 'dsl' can use this object to run the script. For executing a script, the system will call the interpreter's execute method.

storage_scheme=

Signature: void **storage_scheme=** (Macro::Format scheme)

Description: Sets the storage scheme (the format as which the macro is stored)

This value indicates how files for this DSL macro type shall be stored. The value can be one of the constants PlainTextFormat, PlainTextWithHashAnnotationsFormat and MacroFormat.

Use this attribute setter in the initializer before registering the interpreter.

Before version 0.25 this attribute was a re-implementable method. It has been turned into an attribute for performance reasons in version 0.25.

Python specific notes:
The object exposes a writable attribute 'storage_scheme'. This is the setter.

suffix=

Signature: void **suffix=** (string suffix)

Description: Sets the file suffix

This string defines which file suffix to associate with the DSL macro. If an empty string is given (the default) no particular suffix is assciated with that macro type and "lym" is assumed. Use this attribute setter in the initializer before registering the interpreter.

Before version 0.25 this attribute was a re-implementable method. It has been turned into an attribute for performance reasons in version 0.25.

Python specific notes:
The object exposes a writable attribute 'suffix'. This is the setter.

supports_include_expansio

Signature: void **supports_include_expansion=** (bool flag)

Description: Sets a value indicating whether this interpreter supports the default include file expansion scheme.

If this value is set to true (the default), lines like '# %include ...' will be substituted by the content of the file following the '%include' keyword. Set this value to false if you don't want to support this feature.

This attribute has been introduced in version 0.27.

Python specific notes:
The object exposes a writable attribute 'supports_include_expansion'. This is the setter.

syntax_scheme=

Signature: void **syntax_scheme=** (string scheme)

Description: Sets a string indicating the syntax highlighter scheme

The scheme string can be empty (indicating no syntax highlighting), "ruby" for the Ruby syntax highlighter or another string. In that case, the highlighter will look for a syntax definition under the resource path ":/syntax/<scheme>.xml".

Use this attribute setter in the initializer before registering the interpreter.

Before version 0.25 this attribute was a re-implementable method. It has been turned into an attribute for performance reasons in version 0.25.

Python specific notes:
The object exposes a writable attribute 'syntax_scheme'. This is the setter.

4.224. API reference - Class Macro

Notation used in Ruby API documentation

Module: lay

Description: A macro class

Sub-classes: Format, Interpreter

This class is provided mainly to support generation of template macros in the DSL interpreter framework provided by MacroInterpreter. The implementation may be enhanced in future versions and provide access to macros stored inside KLayout's macro repository. But it can be used to execute macro code in a consistent way:

```
path = "path-to-macro.lym"
RBA::Macro::new(path).run()
```

Using the Macro class with run for executing code will chose the right interpreter and is able to execute DRC and LVS scripts in the proper environment. This also provides an option to execute Ruby code from Python and vice versa.

In this scenario you can pass values to the script using Interpreter#define_variable. The interpreter to choose for DRC and LVS scripts is Interpreter#ruby_interpreter. For passing values back from the script, wrap the variable value into a Value object which can be modified by the called script and read back by the caller.

Public constructors

new Macro ptr	**new**	(string path)		Loads the macro from the given file path

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	string	**category**		Gets the category tags
	void	**category=**	(string string)	Sets the category tags string
[const]	string	**description**		Gets the description text
	void	**description=**	(string description)	Sets the description text
[const]	string	**doc**		Gets the macro's documentation string

	void	**doc=**	(string doc)	Sets the macro's documentation string
[const]	string	**dsl_interpreter**		Gets the macro's DSL interpreter name (if interpreter is DSLInterpreter)
	void	**dsl_interpreter=**	(string dsl_interpreter)	Sets the macro's DSL interpreter name (if interpreter is DSLInterpreter)
[const]	string	**epilog**		Gets the epilog code
	void	**epilog=**	(string string)	Sets the epilog
[const]	Macro::Format	**format**		Gets the macro's storage format
	void	**format=**	(Macro::Format format)	Sets the macro's storage format
[const]	string	**group_name**		Gets the menu group name
	void	**group_name=**	(string string)	Sets the menu group name
[const]	Macro::Interpreter	**interpreter**		Gets the macro's interpreter
	void	**interpreter=**	(Macro::Interpreter interpreter)	Sets the macro's interpreter
[const]	string	**interpreter_name**		Gets the macro interpreter name
	void	**is_autorun=**	(bool flag)	Sets a flag indicating whether the macro is automatically executed on startup
[const]	bool	**is_autorun?**		Gets a flag indicating whether the macro is automatically executed on startup
	void	**is_autorun_early=**	(bool flag)	Sets a flag indicating whether the macro is automatically executed early on startup
[const]	bool	**is_autorun_early?**		Gets a flag indicating whether the macro is automatically executed early on startup
[const]	string	**menu_path**		Gets the menu path
	void	**menu_path=**	(string string)	Sets the menu path
[const]	string	**name**		Gets the name of the macro
[const]	string	**path**		Gets the path of the macro
[const]	string	**prolog**		Gets the prolog code
	void	**prolog=**	(string string)	Sets the prolog
[const]	int	**run**		Executes the macro
	void	**save_to**	(string path)	Saves the macro to the given file
[const]	string	**shortcut**		Gets the macro's keyboard shortcut

	void	**shortcut=**	(string shortcut)	Sets the macro's keyboard shortcut
	void	**show_in_menu=**	(bool flag)	Sets a value indicating whether the macro shall be shown in the menu
[const]	bool	**show_in_menu?**		Gets a value indicating whether the macro shall be shown in the menu
	void	**sync_properties_with_text**		Synchronizes the macro properties with the text
	void	**sync_text_with_propertie**		Synchronizes the macro text with the properties
[const]	string	**text**		Gets the macro text
	void	**text=**	(string string)	Sets the macro text
[const]	string	**version**		Gets the macro's version
	void	**version=**	(string version)	Sets the macro's version

Public static methods and constants

[static,const]	Macro::Interpreter	**DSLInterpreter**		A domain-specific interpreter (DSL)
[static,const]	Macro::Format	**MacroFormat**		The macro has macro (XML) format
[static,const]	Macro::Interpreter	**None**		No specific interpreter
[static,const]	Macro::Format	**PlainTextFormat**		The macro has plain text format
[static,const]	Macro::Format	**PlainTextWithHashAnn**		The macro has plain text format with special pseudo-comment annotations
[static,const]	Macro::Interpreter	**Python**		The interpreter is Python
[static,const]	Macro::Interpreter	**Ruby**		The interpreter is Ruby
[static,const]	Macro::Interpreter	**Text**		Plain text
	Macro ptr	**macro_by_path**	(string path)	Finds the macro by installation path
	int	**real_line**	(string path, int line)	Gets the real line number for an include-encoded path and line number
	string	**real_path**	(string path, int line)	Gets the real path for an include-encoded path and line number

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

DSLInterpreter

Signature: *[static,const]* Macro::Interpreter **DSLInterpreter**

Description: A domain-specific interpreter (DSL)

Python specific notes:
The object exposes a readable attribute 'DSLInterpreter'. This is the getter.

MacroFormat

Signature: *[static,const]* Macro::Format **MacroFormat**

Description: The macro has macro (XML) format

Python specific notes:
The object exposes a readable attribute 'MacroFormat'. This is the getter.

None

Signature: *[static,const]* Macro::Interpreter **None**

Description: No specific interpreter

Python specific notes:
This member is available as 'None_' in Python.
The object exposes a readable attribute 'None_'. This is the getter.

PlainTextFormat

Signature: *[static,const]* Macro::Format **PlainTextFormat**

Description: The macro has plain text format

Python specific notes:
The object exposes a readable attribute 'PlainTextFormat'. This is the getter.

PlainTextWithHashAnnotat

Signature: *[static,const]* Macro::Format **PlainTextWithHashAnnotationsFormat**

Description: The macro has plain text format with special pseudo-comment annotations

Python specific notes:
The object exposes a readable attribute 'PlainTextWithHashAnnotationsFormat'. This is the getter.

Python

Signature: *[static,const]* Macro::Interpreter **Python**

Description: The interpreter is Python

Python specific notes:
The object exposes a readable attribute 'Python'. This is the getter.

Ruby

Signature: *[static,const]* Macro::Interpreter **Ruby**

Description: The interpreter is Ruby

Python specific notes:

The object exposes a readable attribute 'Ruby'. This is the getter.

Text

Signature: *[static,const]* Macro::Interpreter **Text**

Description: Plain text

Python specific notes:
The object exposes a readable attribute 'Text'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

category

Signature: *[const]* string **category**

Description: Gets the category tags

The category tags string indicates to which categories a macro will belong to. This string is only used for templates currently and is a comma-separated list of category names.

Python specific notes:
The object exposes a readable attribute 'category'. This is the getter.

category=

Signature: void **category=** (string string)

Description: Sets the category tags string

See category for details.

Python specific notes:
The object exposes a writable attribute 'category'. This is the setter.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

description

Signature: *[const]* string **description**

Description: Gets the description text

The description text of a macro will appear in the macro list. If used as a macro template, the description text can have the format "Group;;Description". In that case, the macro will appear in a group with title "Group".

Python specific notes:
The object exposes a readable attribute 'description'. This is the getter.

description=

Signature: void **description=** (string description)

Description: Sets the description text

description: The description text.

See description for details.

Python specific notes:
The object exposes a writable attribute 'description'. This is the setter.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

	This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
doc	**Signature**: *[const]* string **doc** **Description**: Gets the macro's documentation string This method has been introduced in version 0.27.5. **Python specific notes:** The object exposes a readable attribute 'doc'. This is the getter.
doc=	**Signature**: void **doc=** (string doc) **Description**: Sets the macro's documentation string This method has been introduced in version 0.27.5. **Python specific notes:** The object exposes a writable attribute 'doc'. This is the setter.
dsl_interpreter	**Signature**: *[const]* string **dsl_interpreter** **Description**: Gets the macro's DSL interpreter name (if interpreter is DSLInterpreter) This method has been introduced in version 0.27.5. **Python specific notes:** The object exposes a readable attribute 'dsl_interpreter'. This is the getter.
dsl_interpreter=	**Signature**: void **dsl_interpreter=** (string dsl_interpreter) **Description**: Sets the macro's DSL interpreter name (if interpreter is DSLInterpreter) This method has been introduced in version 0.27.5. **Python specific notes:** The object exposes a writable attribute 'dsl_interpreter'. This is the setter.
epilog	**Signature**: *[const]* string **epilog** **Description**: Gets the epilog code The epilog is executed after the actual code is executed. Interpretation depends on the implementation of the DSL interpreter for DSL macros. **Python specific notes:** The object exposes a readable attribute 'epilog'. This is the getter.
epilog=	**Signature**: void **epilog=** (string string) **Description**: Sets the epilog See epilog for details. **Python specific notes:** The object exposes a writable attribute 'epilog'. This is the setter.
format	**Signature**: *[const]* Macro::Format **format** **Description**: Gets the macro's storage format This method has been introduced in version 0.27.5. **Python specific notes:**

The object exposes a readable attribute 'format'. This is the getter.

format=

Signature: void **format=** (Macro::Format format)

Description: Sets the macro's storage format

This method has been introduced in version 0.27.5.

Python specific notes:
The object exposes a writable attribute 'format'. This is the setter.

group_name

Signature: *[const]* string **group_name**

Description: Gets the menu group name

If a group name is specified and show_in_menu? is true, the macro will appear in a separate group (separated by a separator) together with other macros sharing the same group.

Python specific notes:
The object exposes a readable attribute 'group_name'. This is the getter.

group_name=

Signature: void **group_name=** (string string)

Description: Sets the menu group name

See group_name for details.

Python specific notes:
The object exposes a writable attribute 'group_name'. This is the setter.

interpreter

Signature: *[const]* Macro::Interpreter **interpreter**

Description: Gets the macro's interpreter

This method has been introduced in version 0.27.5.

Python specific notes:
The object exposes a readable attribute 'interpreter'. This is the getter.

interpreter=

Signature: void **interpreter=** (Macro::Interpreter interpreter)

Description: Sets the macro's interpreter

This method has been introduced in version 0.27.5.

Python specific notes:
The object exposes a writable attribute 'interpreter'. This is the setter.

interpreter_name

Signature: *[const]* string **interpreter_name**

Description: Gets the macro interpreter name

This is the string version of interpreter.

This method has been introduced in version 0.27.5.

is_autorun=

Signature: void **is_autorun=** (bool flag)

Description: Sets a flag indicating whether the macro is automatically executed on startup

This method has been introduced in version 0.27.5.

Python specific notes:
The object exposes a writable attribute 'is_autorun'. This is the setter.

is_autorun?

Signature: *[const]* bool **is_autorun?**

Description: Gets a flag indicating whether the macro is automatically executed on startup

This method has been introduced in version 0.27.5.

Python specific notes:
The object exposes a readable attribute 'is_autorun'. This is the getter.

is_autorun_early=

Signature: void **is_autorun_early=** (bool flag)

Description: Sets a flag indicating whether the macro is automatically executed early on startup

This method has been introduced in version 0.27.5.

Python specific notes:
The object exposes a writable attribute 'is_autorun_early'. This is the setter.

is_autorun_early?

Signature: *[const]* bool **is_autorun_early?**

Description: Gets a flag indicating whether the macro is automatically executed early on startup

This method has been introduced in version 0.27.5.

Python specific notes:
The object exposes a readable attribute 'is_autorun_early'. This is the getter.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

macro_by_path

Signature: *[static]* Macro ptr **macro_by_path** (string path)

Description: Finds the macro by installation path

Returns nil if no macro with this path can be found.

This method has been added in version 0.26.

menu_path

Signature: *[const]* string **menu_path**

Description: Gets the menu path

If a menu path is specified and show_in_menu? is true, the macro will appear in the menu at the specified position.

Python specific notes:
The object exposes a readable attribute 'menu_path'. This is the getter.

menu_path=

Signature: void **menu_path=** (string string)

Description: Sets the menu path

See menu_path for details.

Python specific notes:
The object exposes a writable attribute 'menu_path'. This is the setter.

name

Signature: *[const]* string **name**

Description: Gets the name of the macro

This attribute has been added in version 0.25.

new

Signature: *[static]* new Macro ptr **new** (string path)

Description: Loads the macro from the given file path

This constructor has been introduced in version 0.27.5.

Python specific notes:
This method is the default initializer of the object.

path

Signature: *[const]* string **path**

Description: Gets the path of the macro

The path is the path where the macro is stored, starting with an abstract group identifier. The path is used to identify the macro in the debugger for example.

prolog

Signature: *[const]* string **prolog**

Description: Gets the prolog code

The prolog is executed before the actual code is executed. Interpretation depends on the implementation of the DSL interpreter for DSL macros.

Python specific notes:
The object exposes a readable attribute 'prolog'. This is the getter.

prolog=

Signature: void **prolog=** (string string)

Description: Sets the prolog

See prolog for details.

Python specific notes:
The object exposes a writable attribute 'prolog'. This is the setter.

real_line

Signature: *[static]* int **real_line** (string path, int line)

Description: Gets the real line number for an include-encoded path and line number

When using KLayout's include scheme based on '# %include ...', __FILE__ and __LINE__ (Ruby) will not have the proper values but encoded file names. This method allows retrieving the real line number by using

```
# Ruby
real_line = RBA::Macro::real_line(__FILE__, __LINE__)

# Python
real_line = pya::Macro::real_line(__file__, __line__)
```

This substitution is not required for top-level macros as KLayout's interpreter will automatically use this function instead of __FILE__. Call this function when you need __FILE__ from files included through the languages mechanisms such as 'require' or 'load' where this substitution does not happen.

For Python there is no equivalent for __LINE__, so you always have to use:

```
# Pythonimport inspect
```

```
real_line = pya.Macro.real_line(__file__,
 inspect.currentframe().f_back.f_lineno)
```

This feature has been introduced in version 0.27.

real_path

Signature: *[static]* string **real_path** (string path, int line)

Description: Gets the real path for an include-encoded path and line number

When using KLayout's include scheme based on '# %include ...', __FILE__ and __LINE__ (Ruby) will not have the proper values but encoded file names. This method allows retrieving the real file by using

```
# Ruby
real_file = RBA::Macro::real_path(__FILE__, __LINE__)
```

This substitution is not required for top-level macros as KLayout's interpreter will automatically use this function instead of __FILE__. Call this function when you need __FILE__ from files included through the languages mechanisms such as 'require' or 'load' where this substitution does not happen.

For Python there is no equivalent for __LINE__, so you always have to use:

```
# Pythonimport inspect
real_file = pya.Macro.real_path(__file__,
 inspect.currentframe().f_back.f_lineno)
```

This feature has been introduced in version 0.27.

run

Signature: *[const]* int **run**

Description: Executes the macro

This method has been introduced in version 0.27.5.

save_to

Signature: void **save_to** (string path)

Description: Saves the macro to the given file

This method has been introduced in version 0.27.5.

shortcut

Signature: *[const]* string **shortcut**

Description: Gets the macro's keyboard shortcut

This method has been introduced in version 0.27.5.

Python specific notes:
The object exposes a readable attribute 'shortcut'. This is the getter.

shortcut=

Signature: void **shortcut=** (string shortcut)

Description: Sets the macro's keyboard shortcut

This method has been introduced in version 0.27.5.

Python specific notes:

	The object exposes a writable attribute 'shortcut'. This is the setter.
show_in_menu=	**Signature**: void **show_in_menu=** (bool flag) **Description**: Sets a value indicating whether the macro shall be shown in the menu **Python specific notes:** The object exposes a writable attribute 'show_in_menu'. This is the setter.
show_in_menu?	**Signature**: *[const]* bool **show_in_menu?** **Description**: Gets a value indicating whether the macro shall be shown in the menu **Python specific notes:** The object exposes a readable attribute 'show_in_menu'. This is the getter.
sync_properties_with_text	**Signature**: void **sync_properties_with_text** **Description**: Synchronizes the macro properties with the text This method performs the reverse process of sync_text_with_properties. This method has been introduced in version 0.27.5.
sync_text_with_properties	**Signature**: void **sync_text_with_properties** **Description**: Synchronizes the macro text with the properties This method applies to PlainTextWithHashAnnotationsFormat format. The macro text will be enhanced with pseudo-comments reflecting the macro properties. This way, the macro properties can be stored in plain files. This method has been introduced in version 0.27.5.
text	**Signature**: *[const]* string **text** **Description**: Gets the macro text The text is the code executed by the macro interpreter. Depending on the DSL interpreter, the text can be any kind of code. **Python specific notes:** The object exposes a readable attribute 'text'. This is the getter.
text=	**Signature**: void **text=** (string string) **Description**: Sets the macro text See text for details. **Python specific notes:** The object exposes a writable attribute 'text'. This is the setter.
version	**Signature**: *[const]* string **version** **Description**: Gets the macro's version This method has been introduced in version 0.27.5. **Python specific notes:** The object exposes a readable attribute 'version'. This is the getter.
version=	**Signature**: void **version=** (string version) **Description**: Sets the macro's version

This method has been introduced in version 0.27.5.

Python specific notes:
The object exposes a writable attribute 'version'. This is the setter.

4.225. API reference - Class Macro::Format

Notation used in Ruby API documentation

Module: lay

Description: Specifies the format of a macro

This class is equivalent to the class Macro::Format

This enum has been introduced in version 0.27.5.

Public constructors

new Macro::Format ptr	**new**	(int i)	Creates an enum from an integer value
new Macro::Format ptr	**new**	(string s)	Creates an enum from a string value

Public methods

[const]	bool	**!=**	(const Macro::Format other)	Compares two enums for inequality
[const]	bool	**!=**	(int other)	Compares an enum with an integer for inequality
[const]	bool	**<**	(const Macro::Format other)	Returns true if the first enum is less (in the enum symbol order) than the second
[const]	bool	**<**	(int other)	Returns true if the enum is less (in the enum symbol order) than the integer value
[const]	bool	**==**	(const Macro::Format other)	Compares two enums
[const]	bool	**==**	(int other)	Compares an enum with an integer value
[const]	int	**hash**		Gets the hash value from the enum
[const]	string	**inspect**		Converts an enum to a visual string
[const]	int	**to_i**		Gets the integer value from the enum
[const]	string	**to_s**		Gets the symbolic string from an enum

Public static methods and constants

[static,const]	Macro::Format	**MacroFormat**	The macro has macro (XML) format
[static,const]	Macro::Format	**PlainTextFormat**	The macro has plain text format
[static,const]	Macro::Format	**PlainTextWithHashAnnotat**	The macro has plain text format with special pseudo-comment annotations

Detailed description

!=	**(1) Signature**: *[const]* bool **!=** (const Macro::Format other) **Description**: Compares two enums for inequality **(2) Signature**: *[const]* bool **!=** (int other) **Description**: Compares an enum with an integer for inequality
<	**(1) Signature**: *[const]* bool **<** (const Macro::Format other) **Description**: Returns true if the first enum is less (in the enum symbol order) than the second **(2) Signature**: *[const]* bool **<** (int other) **Description**: Returns true if the enum is less (in the enum symbol order) than the integer value
==	**(1) Signature**: *[const]* bool **==** (const Macro::Format other) **Description**: Compares two enums **(2) Signature**: *[const]* bool **==** (int other) **Description**: Compares an enum with an integer value
MacroFormat	**Signature**: *[static,const]* Macro::Format **MacroFormat** **Description**: The macro has macro (XML) format **Python specific notes:** The object exposes a readable attribute 'MacroFormat'. This is the getter.
PlainTextFormat	**Signature**: *[static,const]* Macro::Format **PlainTextFormat** **Description**: The macro has plain text format **Python specific notes:** The object exposes a readable attribute 'PlainTextFormat'. This is the getter.
PlainTextWithHashAnnotationsFormat	**Signature**: *[static,const]* Macro::Format **PlainTextWithHashAnnotationsFormat** **Description**: The macro has plain text format with special pseudo-comment annotations **Python specific notes:** The object exposes a readable attribute 'PlainTextWithHashAnnotationsFormat'. This is the getter.
hash	**Signature**: *[const]* int **hash** **Description**: Gets the hash value from the enum **Python specific notes:** This method is also available as 'hash(object)'.
inspect	**Signature**: *[const]* string **inspect** **Description**: Converts an enum to a visual string **Python specific notes:** This method is also available as 'repr(object)'.

new	**(1) Signature**: *[static]* new Macro::Format ptr **new** (int i) **Description**: Creates an enum from an integer value **Python specific notes:** This method is the default initializer of the object. **(2) Signature**: *[static]* new Macro::Format ptr **new** (string s) **Description**: Creates an enum from a string value **Python specific notes:** This method is the default initializer of the object.
to_i	**Signature**: *[const]* int **to_i** **Description**: Gets the integer value from the enum **Python specific notes:** This method is also available as 'int(object)'.
to_s	**Signature**: *[const]* string **to_s** **Description**: Gets the symbolic string from an enum **Python specific notes:** This method is also available as 'str(object)'.

4.226. API reference - Class Macro::Interpreter

Notation used in Ruby API documentation

Module: lay

Description: Specifies the interpreter used for executing a macro

This class is equivalent to the class Macro::Interpreter

This enum has been introduced in version 0.27.5.

Public constructors

new Macro::Interpreter ptr	**new**	(int i)	Creates an enum from an integer value
new Macro::Interpreter ptr	**new**	(string s)	Creates an enum from a string value

Public methods

[const]	bool	**!=**	(const Macro::Interpreter other)	Compares two enums for inequality
[const]	bool	**!=**	(int other)	Compares an enum with an integer for inequality
[const]	bool	**<**	(const Macro::Interpreter other)	Returns true if the first enum is less (in the enum symbol order) than the second
[const]	bool	**<**	(int other)	Returns true if the enum is less (in the enum symbol order) than the integer value
[const]	bool	**==**	(const Macro::Interpreter other)	Compares two enums
[const]	bool	**==**	(int other)	Compares an enum with an integer value
[const]	int	**hash**		Gets the hash value from the enum
[const]	string	**inspect**		Converts an enum to a visual string
[const]	int	**to_i**		Gets the integer value from the enum
[const]	string	**to_s**		Gets the symbolic string from an enum

Public static methods and constants

[static,const]	Macro::Interpreter	**DSLInterpreter**	A domain-specific interpreter (DSL)
[static,const]	Macro::Interpreter	**None**	No specific interpreter
[static,const]	Macro::Interpreter	**Python**	The interpreter is Python
[static,const]	Macro::Interpreter	**Ruby**	The interpreter is Ruby

[static,const]	Macro::Interpreter	**Text**	Plain text

Detailed description

!=	**(1) Signature**: *[const]* bool **!=** (const Macro::Interpreter other) **Description**: Compares two enums for inequality **(2) Signature**: *[const]* bool **!=** (int other) **Description**: Compares an enum with an integer for inequality
<	**(1) Signature**: *[const]* bool **<** (const Macro::Interpreter other) **Description**: Returns true if the first enum is less (in the enum symbol order) than the second **(2) Signature**: *[const]* bool **<** (int other) **Description**: Returns true if the enum is less (in the enum symbol order) than the integer value
==	**(1) Signature**: *[const]* bool **==** (const Macro::Interpreter other) **Description**: Compares two enums **(2) Signature**: *[const]* bool **==** (int other) **Description**: Compares an enum with an integer value
DSLInterpreter	**Signature**: *[static,const]* Macro::Interpreter **DSLInterpreter** **Description**: A domain-specific interpreter (DSL) **Python specific notes:** The object exposes a readable attribute 'DSLInterpreter'. This is the getter.
None	**Signature**: *[static,const]* Macro::Interpreter **None** **Description**: No specific interpreter **Python specific notes:** This member is available as 'None_' in Python. The object exposes a readable attribute 'None_'. This is the getter.
Python	**Signature**: *[static,const]* Macro::Interpreter **Python** **Description**: The interpreter is Python **Python specific notes:** The object exposes a readable attribute 'Python'. This is the getter.
Ruby	**Signature**: *[static,const]* Macro::Interpreter **Ruby** **Description**: The interpreter is Ruby **Python specific notes:** The object exposes a readable attribute 'Ruby'. This is the getter.
Text	**Signature**: *[static,const]* Macro::Interpreter **Text** **Description**: Plain text

Python specific notes:
The object exposes a readable attribute 'Text'. This is the getter.

hash

Signature: *[const]* int **hash**

Description: Gets the hash value from the enum

Python specific notes:
This method is also available as 'hash(object)'.

inspect

Signature: *[const]* string **inspect**

Description: Converts an enum to a visual string

Python specific notes:
This method is also available as 'repr(object)'.

new

(1) Signature: *[static]* new Macro::Interpreter ptr **new** (int i)

Description: Creates an enum from an integer value

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new Macro::Interpreter ptr **new** (string s)

Description: Creates an enum from a string value

Python specific notes:
This method is the default initializer of the object.

to_i

Signature: *[const]* int **to_i**

Description: Gets the integer value from the enum

Python specific notes:
This method is also available as 'int(object)'.

to_s

Signature: *[const]* string **to_s**

Description: Gets the symbolic string from an enum

Python specific notes:
This method is also available as 'str(object)'.

4.227. API reference - Class Annotation

Notation used in Ruby API documentation

Module: lay

Description: A layout annotation (i.e. ruler)

Class hierarchy: Annotation

Annotation objects provide a way to attach measurements or descriptive information to a layout view. Annotation objects can appear as rulers for example. Annotation objects can be configured in different ways using the styles provided. By configuring an annotation object properly, it can appear as a rectangle or a plain line for example. See Ruler properties for more details about the appearance options.

Annotations are inserted into a layout view using LayoutView#insert_annotation. Here is some sample code in Ruby:

```
app = RBA::Application.instance
mw = app.main_window
view = mw.current_view

ant = RBA::Annotation::new
ant.p1 = RBA::DPoint::new(0, 0)
ant.p2 = RBA::DPoint::new(100, 0)
ant.style = RBA::Annotation::StyleRuler
view.insert_annotation(ant)
```

Annotations can be retrieved from a view with LayoutView#each_annotation and all annotations can be cleared with LayoutView#clear_annotations.

Starting with version 0.25, annotations are 'live' objects once they are inserted into the view. Changing properties of annotations will automatically update the view (however, that is not true the other way round).

Here is some sample code of changing the style of all rulers to two-sided arrows:

```
view = RBA::LayoutView::current

begin

  view.transaction("Restyle annotations")

  view.each_annotation do |a|
    a.style = RBA::Annotation::StyleArrowBoth
  end

ensure
  view.commit
end
```

Public constructors

new Annotation ptr	**new**	Creates a new object of this class

Public methods

[const]	bool	**!=**	(const Annotation other)	Inequality operator

[const]	bool	==	(const Annotation other)	Equality operator
	void	_assign	(const Annotation other)	Assigns another object to self
	void	_create		Ensures the C++ object is created
	void	_destroy		Explicitly destroys the object
[const]	bool	_destroyed?		Returns a value indicating whether the object was already destroyed
[const]	new Annotation ptr	_dup		Creates a copy of self
[const]	bool	_is_const_object?		Returns a value indicating whether the reference is a const reference
	void	_manage		Marks the object as managed by the script side.
	void	_unmanage		Marks the object as no longer owned by the script side.
[const]	int	angle_constraint		Returns the angle constraint attribute
	void	angle_constraint=	(int flag)	Sets the angle constraint attribute
	void	assign	(const Annotation other)	Assigns another object to self
[const]	DBox	box		Gets the bounding box of the object (not including text)
[const]	string	category		Gets the category string
	void	category=	(string cat)	Sets the category string of the annotation
	void	delete		Deletes this annotation from the view
	void	detach		Detaches the annotation object from the view
[const]	new Annotation ptr	dup		Creates a copy of self
[const]	string	fmt		Returns the format used for the label
	void	fmt=	(string format)	Sets the format used for the label
[const]	string	fmt_x		Returns the format used for the x-axis label
	void	fmt_x=	(string format)	Sets the format used for the x-axis label
[const]	string	fmt_y		Returns the format used for the y-axis label

	void	**fmt_y=**	(string format)	Sets the format used for the y-axis label
[const]	int	**id**		Returns the annotation's ID
[const]	bool	**is_valid?**		Returns a value indicating whether the object is a valid reference.
[const]	int	**main_position**		Gets the position of the main label
	void	**main_position=**	(int pos)	Sets the position of the main label
[const]	int	**main_xalign**		Gets the horizontal alignment type of the main label
	void	**main_xalign=**	(int align)	Sets the horizontal alignment type of the main label
[const]	int	**main_yalign**		Gets the vertical alignment type of the main label
	void	**main_yalign=**	(int align)	Sets the vertical alignment type of the main label
[const]	int	**outline**		Returns the outline style of the annotation object
	void	**outline=**	(int outline)	Sets the outline style used for drawing the annotation object
[const]	DPoint	**p1**		Gets the first point of the ruler or marker
	void	**p1=**	(const DPoint point)	Sets the first point of the ruler or marker
[const]	DPoint	**p2**		Gets the second point of the ruler or marker
	void	**p2=**	(const DPoint point)	Sets the second point of the ruler or marker
[const]	DPoint[]	**points**		Gets the points of the ruler
	void	**points=**	(DPoint[] points)	Sets the points for a (potentially) multi-segmented ruler
[const]	DPoint	**seg_p1**	(unsigned long segment_index)	Gets the first point of the given segment.
[const]	DPoint	**seg_p2**	(unsigned long segment_index)	Gets the second point of the given segment.
[const]	unsigned long	**segments**		Gets the number of segments.
	void	**snap=**	(bool flag)	Sets the 'snap to objects' attribute
[const]	bool	**snap?**		Returns the 'snap to objects' attribute
[const]	int	**style**		Returns the style of the annotation object
	void	**style=**	(int style)	Sets the style used for drawing the annotation object

[const]	string	**text**	(unsigned long index = 0)	Returns the formatted text for the main label
[const]	string	**text_x**	(unsigned long index = 0)	Returns the formatted text for the x-axis label
[const]	string	**text_y**	(unsigned long index = 0)	Returns the formatted text for the y-axis label
[const]	string	**to_s**		Returns the string representation of the ruler
[const]	Annotation	**transformed**	(const DTrans t)	Transforms the ruler or marker with the given simple transformation
[const]	Annotation	**transformed**	(const DCplxTrans t)	Transforms the ruler or marker with the given complex transformation
[const]	Annotation	**transformed**	(const ICplxTrans t)	Transforms the ruler or marker with the given complex transformation
[const]	int	**xlabel_xalign**		Gets the horizontal alignment type of the x axis label
	void	**xlabel_xalign=**	(int align)	Sets the horizontal alignment type of the x axis label
[const]	int	**xlabel_yalign**		Gets the vertical alignment type of the x axis label
	void	**xlabel_yalign=**	(int align)	Sets the vertical alignment type of the x axis label
[const]	int	**ylabel_xalign**		Gets the horizontal alignment type of the y axis label
	void	**ylabel_xalign=**	(int align)	Sets the horizontal alignment type of the y axis label
[const]	int	**ylabel_yalign**		Gets the vertical alignment type of the y axis label
	void	**ylabel_yalign=**	(int align)	Sets the vertical alignment type of the y axis label

Public static methods and constants

int	**AlignAuto**	This code indicates automatic alignment.
int	**AlignBottom**	This code indicates bottom alignment.
int	**AlignCenter**	This code indicates automatic alignment.
int	**AlignDown**	This code indicates left or bottom alignment, depending on the context.
int	**AlignLeft**	This code indicates left alignment.

int	**AlignRight**	This code indicates right alignment.
int	**AlignTop**	This code indicates top alignment.
int	**AlignUp**	This code indicates right or top alignment, depending on the context.
int	**AngleAny**	Gets the any angle code for use with the angle_constraint method
int	**AngleDiagonal**	Gets the diagonal angle code for use with the angle_constraint method
int	**AngleGlobal**	Gets the global angle code for use with the angle_constraint method.
int	**AngleHorizontal**	Gets the horizontal angle code for use with the angle_constraint method
int	**AngleOrtho**	Gets the ortho angle code for use with the angle_constraint method
int	**AngleVertical**	Gets the vertical angle code for use with the angle_constraint method
int	**OutlineAngle**	Gets the angle measurement ruler outline code for use with the outline method
int	**OutlineBox**	Gets the box outline code for use with the outline method
int	**OutlineDiag**	Gets the diagonal output code for use with the outline method
int	**OutlineDiagXY**	outline_xy code used by the outline method
int	**OutlineDiagYX**	Gets the yx plus diagonal outline code for use with the outline method
int	**OutlineEllipse**	Gets the ellipse outline code for use with the outline method
int	**OutlineRadius**	Gets the radius measurement ruler outline code for use with the outline method
int	**OutlineXY**	Gets the xy outline code for use with the outline method
int	**OutlineYX**	Gets the yx outline code for use with the outline method
int	**PositionAuto**	This code indicates automatic positioning.
int	**PositionCenter**	This code indicates positioning of the main label at the mid point between p1 and p2.
int	**PositionP1**	This code indicates positioning of the main label at p1.
int	**PositionP2**	This code indicates positioning of the main label at p2.
int	**RulerModeAutoMetric**	Specifies auto-metric ruler mode for the register_template method

	int	**RulerModeAutoMetricEdge**		Specifies edge-sensitive auto-metric ruler mode for the register_template method
	int	**RulerModeNormal**		Specifies normal ruler mode for the register_template method
	int	**RulerModeSingleClick**		Specifies single-click ruler mode for the register_template method
	int	**RulerMultiSegment**		Specifies multi-segment mode
	int	**RulerThreeClicks**		Specifies three-click ruler mode for the register_template method
	int	**StyleArrowBoth**		Gets the both arrow ends style code for use the style method
	int	**StyleArrowEnd**		Gets the end arrow style code for use the style method
	int	**StyleArrowStart**		Gets the start arrow style code for use the style method
	int	**StyleCrossBoth**		Gets the line style code for use with the style method
	int	**StyleCrossEnd**		Gets the line style code for use with the style method
	int	**StyleCrossStart**		Gets the line style code for use with the style method
	int	**StyleLine**		Gets the line style code for use with the style method
	int	**StyleRuler**		Gets the ruler style code for use the style method
	new Annotation ptr	**from_s**	(string s)	Creates a ruler from a string representation
	void	**register_template**	(const Annotatic annotatic string title, int mode = RulerMo	Registers the given annotation as a template globally
	void	**unregister_templates**	(string category)	Unregisters the template or templates with the given category string globally

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**		Use of this method is deprecated. Use _create instead
	void	**destroy**		Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**		Use of this method is deprecated. Use _destroyed? instead

[const]	bool	**is_const_object?**		Use of this method is deprecated. Use _is_const_object? instead
[const]	Annotation	**transformed_cplx**	(const DCplxTrans t)	Use of this method is deprecated. Use transformed instead
[const]	Annotation	**transformed_cplx**	(const ICplxTrans t)	Use of this method is deprecated. Use transformed instead

Detailed description

!=

Signature: *[const]* bool **!=** (const Annotation other)

Description: Inequality operator

==

Signature: *[const]* bool **==** (const Annotation other)

Description: Equality operator

AlignAuto

Signature: *[static]* int **AlignAuto**

Description: This code indicates automatic alignment.

This code makes the annotation align the label the way it thinks is best.

This constant has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'AlignAuto'. This is the getter.

AlignBottom

Signature: *[static]* int **AlignBottom**

Description: This code indicates bottom alignment.

If used in a vertical context, this alignment code makes the label aligned at the bottom side - i.e. it will appear top of the reference point.

This constant has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'AlignBottom'. This is the getter.

AlignCenter

Signature: *[static]* int **AlignCenter**

Description: This code indicates automatic alignment.

This code makes the annotation align the label centered. When used in a horizontal context, centering is in horizontal direction. If used in a vertical context, centering is in vertical direction.

This constant has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'AlignCenter'. This is the getter.

AlignDown

Signature: *[static]* int **AlignDown**

Description: This code indicates left or bottom alignment, depending on the context.

This code is equivalent to AlignLeft and AlignBottom.

This constant has been introduced in version 0.25.

Python specific notes:

The object exposes a readable attribute 'AlignDown'. This is the getter.

AlignLeft

Signature: *[static]* int **AlignLeft**

Description: This code indicates left alignment.

If used in a horizontal context, this alignment code makes the label aligned at the left side - i.e. it will appear right of the reference point.

This constant has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'AlignLeft'. This is the getter.

AlignRight

Signature: *[static]* int **AlignRight**

Description: This code indicates right alignment.

If used in a horizontal context, this alignment code makes the label aligned at the right side - i.e. it will appear left of the reference point.

This constant has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'AlignRight'. This is the getter.

AlignTop

Signature: *[static]* int **AlignTop**

Description: This code indicates top alignment.

If used in a vertical context, this alignment code makes the label aligned at the top side - i.e. it will appear bottom of the reference point.

This constant has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'AlignTop'. This is the getter.

AlignUp

Signature: *[static]* int **AlignUp**

Description: This code indicates right or top alignment, depending on the context.

This code is equivalent to AlignRight and AlignTop.

This constant has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'AlignUp'. This is the getter.

AngleAny

Signature: *[static]* int **AngleAny**

Description: Gets the any angle code for use with the angle_constraint method

If this value is specified for the angle constraint, all angles will be allowed.

Python specific notes:
The object exposes a readable attribute 'AngleAny'. This is the getter.

AngleDiagonal

Signature: *[static]* int **AngleDiagonal**

Description: Gets the diagonal angle code for use with the angle_constraint method

If this value is specified for the angle constraint, only multiples of 45 degree are allowed.

Python specific notes:
The object exposes a readable attribute 'AngleDiagonal'. This is the getter.

AngleGlobal

Signature: *[static]* int **AngleGlobal**

Description: Gets the global angle code for use with the angle_constraint method.

This code will tell the ruler or marker to use the angle constraint defined globally.

Python specific notes:
The object exposes a readable attribute 'AngleGlobal'. This is the getter.

AngleHorizontal

Signature: *[static]* int **AngleHorizontal**

Description: Gets the horizontal angle code for use with the angle_constraint method

If this value is specified for the angle constraint, only horizontal rulers are allowed.

Python specific notes:
The object exposes a readable attribute 'AngleHorizontal'. This is the getter.

AngleOrtho

Signature: *[static]* int **AngleOrtho**

Description: Gets the ortho angle code for use with the angle_constraint method

If this value is specified for the angle constraint, only multiples of 90 degree are allowed.

Python specific notes:
The object exposes a readable attribute 'AngleOrtho'. This is the getter.

AngleVertical

Signature: *[static]* int **AngleVertical**

Description: Gets the vertical angle code for use with the angle_constraint method

If this value is specified for the angle constraint, only vertical rulers are allowed.

Python specific notes:
The object exposes a readable attribute 'AngleVertical'. This is the getter.

OutlineAngle

Signature: *[static]* int **OutlineAngle**

Description: Gets the angle measurement ruler outline code for use with the outline method

When this outline style is specified, the ruler is drawn to indicate the angle between the first and last segment.

This constant has been introduced in version 0.28.

Python specific notes:
The object exposes a readable attribute 'OutlineAngle'. This is the getter.

OutlineBox

Signature: *[static]* int **OutlineBox**

Description: Gets the box outline code for use with the outline method

When this outline style is specified, a box is drawn with the corners specified by the start and end point. All box edges are drawn in the style specified with the style attribute.

Python specific notes:
The object exposes a readable attribute 'OutlineBox'. This is the getter.

OutlineDiag

Signature: *[static]* int **OutlineDiag**

Description: Gets the diagonal output code for use with the outline method

When this outline style is specified, a line connecting start and end points in the given style (ruler, arrow or plain line) is drawn.

Python specific notes:
The object exposes a readable attribute 'OutlineDiag'. This is the getter.

OutlineDiagXY

Signature: *[static]* int **OutlineDiagXY**

Description: outline_xy code used by the outline method

When this outline style is specified, three lines are drawn: one horizontal from left to right and attached to the end of that a line from the bottom to the top. Another line is drawn connecting the start and end points directly. The lines are drawn in the specified style (see style method).

Python specific notes:
The object exposes a readable attribute 'OutlineDiagXY'. This is the getter.

OutlineDiagYX

Signature: *[static]* int **OutlineDiagYX**

Description: Gets the yx plus diagonal outline code for use with the outline method

When this outline style is specified, three lines are drawn: one vertical from bottom to top and attached to the end of that a line from the left to the right. Another line is drawn connecting the start and end points directly. The lines are drawn in the specified style (see style method).

Python specific notes:
The object exposes a readable attribute 'OutlineDiagYX'. This is the getter.

OutlineEllipse

Signature: *[static]* int **OutlineEllipse**

Description: Gets the ellipse outline code for use with the outline method

When this outline style is specified, an ellipse is drawn with the extensions specified by the start and end point. The contour drawn as a line.

This constant has been introduced in version 0.26.

Python specific notes:
The object exposes a readable attribute 'OutlineEllipse'. This is the getter.

OutlineRadius

Signature: *[static]* int **OutlineRadius**

Description: Gets the radius measurement ruler outline code for use with the outline method

When this outline style is specified, the ruler is drawn to indicate a radius defined by at least three points of the ruler.

This constant has been introduced in version 0.28.

Python specific notes:
The object exposes a readable attribute 'OutlineRadius'. This is the getter.

OutlineXY

Signature: *[static]* int **OutlineXY**

Description: Gets the xy outline code for use with the outline method

When this outline style is specified, two lines are drawn: one horizontal from left to right and attached to the end of that a line from the bottom to the top. The lines are drawn in the specified style (see style method).

Python specific notes:
The object exposes a readable attribute 'OutlineXY'. This is the getter.

OutlineYX

Signature: *[static]* int **OutlineYX**

Description: Gets the yx outline code for use with the outline method

When this outline style is specified, two lines are drawn: one vertical from bottom to top and attached to the end of that a line from the left to the right. The lines are drawn in the specified style (see style method).

Python specific notes:
The object exposes a readable attribute 'OutlineYX'. This is the getter.

PositionAuto

Signature: *[static]* int **PositionAuto**

Description: This code indicates automatic positioning.

The main label will be put either to p1 or p2, whichever the annotation considers best.

This constant has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'PositionAuto'. This is the getter.

PositionCenter

Signature: *[static]* int **PositionCenter**

Description: This code indicates positioning of the main label at the mid point between p1 and p2.

The main label will be put to the center point.

This constant has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'PositionCenter'. This is the getter.

PositionP1

Signature: *[static]* int **PositionP1**

Description: This code indicates positioning of the main label at p1.

The main label will be put to p1.

This constant has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'PositionP1'. This is the getter.

PositionP2

Signature: *[static]* int **PositionP2**

Description: This code indicates positioning of the main label at p2.

The main label will be put to p2.

This constant has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'PositionP2'. This is the getter.

RulerModeAutoMetric

Signature: *[static]* int **RulerModeAutoMetric**

Description: Specifies auto-metric ruler mode for the register_template method

In auto-metric mode, a ruler can be placed with a single click and p1/p2 will be determined from the neighborhood.

This constant has been introduced in version 0.25

Python specific notes:
The object exposes a readable attribute 'RulerModeAutoMetric'. This is the getter.

RulerModeAutoMetricEdg

Signature: *[static]* int **RulerModeAutoMetricEdge**

Description: Specifies edge-sensitive auto-metric ruler mode for the register_template method

In auto-metric mode, a ruler can be placed with a single click and p1/p2 will be determined from the edge it is placed on.

This constant has been introduced in version 0.29

Python specific notes:
The object exposes a readable attribute 'RulerModeAutoMetricEdge'. This is the getter.

RulerModeNormal

Signature: *[static]* int **RulerModeNormal**

Description: Specifies normal ruler mode for the register_template method

This constant has been introduced in version 0.25

Python specific notes:
The object exposes a readable attribute 'RulerModeNormal'. This is the getter.

RulerModeSingleClick

Signature: *[static]* int **RulerModeSingleClick**

Description: Specifies single-click ruler mode for the register_template method

In single click-mode, a ruler can be placed with a single click and p1 will be == p2.

This constant has been introduced in version 0.25

Python specific notes:
The object exposes a readable attribute 'RulerModeSingleClick'. This is the getter.

RulerMultiSegment

Signature: *[static]* int **RulerMultiSegment**

Description: Specifies multi-segment mode

In multi-segment mode, multiple segments can be created. The ruler is finished with a double click.

This constant has been introduced in version 0.28

Python specific notes:
The object exposes a readable attribute 'RulerMultiSegment'. This is the getter.

RulerThreeClicks

Signature: *[static]* int **RulerThreeClicks**

Description: Specifies three-click ruler mode for the register_template method

In this ruler mode, two segments are created for angle and circle radius measurements. Three mouse clicks are required.

This constant has been introduced in version 0.28

Python specific notes:
The object exposes a readable attribute 'RulerThreeClicks'. This is the getter.

StyleArrowBoth

Signature: *[static]* int **StyleArrowBoth**

Description: Gets the both arrow ends style code for use the style method

When this style is specified, a two-headed arrow is drawn.

Python specific notes:
The object exposes a readable attribute 'StyleArrowBoth'. This is the getter.

StyleArrowEnd

Signature: *[static]* int **StyleArrowEnd**

Description: Gets the end arrow style code for use the style method

When this style is specified, an arrow is drawn pointing from the start to the end point.

Python specific notes:
The object exposes a readable attribute 'StyleArrowEnd'. This is the getter.

StyleArrowStart

Signature: *[static]* int **StyleArrowStart**

Description: Gets the start arrow style code for use the style method

When this style is specified, an arrow is drawn pointing from the end to the start point.

Python specific notes:
The object exposes a readable attribute 'StyleArrowStart'. This is the getter.

StyleCrossBoth

Signature: *[static]* int **StyleCrossBoth**

Description: Gets the line style code for use with the style method

When this style is specified, a cross is drawn at both points.

This constant has been added in version 0.26.

Python specific notes:
The object exposes a readable attribute 'StyleCrossBoth'. This is the getter.

StyleCrossEnd

Signature: *[static]* int **StyleCrossEnd**

Description: Gets the line style code for use with the style method

When this style is specified, a cross is drawn at the end point.

This constant has been added in version 0.26.

Python specific notes:
The object exposes a readable attribute 'StyleCrossEnd'. This is the getter.

StyleCrossStart

Signature: *[static]* int **StyleCrossStart**

Description: Gets the line style code for use with the style method

When this style is specified, a cross is drawn at the start point.

This constant has been added in version 0.26.

Python specific notes:
The object exposes a readable attribute 'StyleCrossStart'. This is the getter.

StyleLine

Signature: *[static]* int **StyleLine**

Description: Gets the line style code for use with the style method

When this style is specified, a plain line is drawn.

Python specific notes:
The object exposes a readable attribute 'StyleLine'. This is the getter.

StyleRuler

Signature: *[static]* int **StyleRuler**

Description: Gets the ruler style code for use the style method

When this style is specified, the annotation will show a ruler with some ticks at distances indicating a decade of units and a suitable subdivision into minor ticks at intervals of 1, 2 or 5 units.

Python specific notes:
The object exposes a readable attribute 'StyleRuler'. This is the getter.

_assign

Signature: void **_assign** (const Annotation other)

Description: Assigns another object to self

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_dup

Signature: *[const]* new Annotation ptr **_dup**

Description: Creates a copy of self

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

angle_constraint

Signature: *[const]* int **angle_constraint**

Description: Returns the angle constraint attribute

See angle_constraint= for a more detailed description.

Python specific notes:
The object exposes a readable attribute 'angle_constraint'. This is the getter.

angle_constraint=

Signature: void **angle_constraint=** (int flag)

Description: Sets the angle constraint attribute

This attribute controls if an angle constraint is applied when moving one of the ruler's points. The Angle... values can be used for this purpose.

Python specific notes:
The object exposes a writable attribute 'angle_constraint'. This is the setter.

assign

Signature: void **assign** (const Annotation other)

Description: Assigns another object to self

box

Signature: *[const]* DBox **box**

Description: Gets the bounding box of the object (not including text)

Returns: The bounding box

category

Signature: *[const]* string **category**

Description: Gets the category string

See category= for details.

This method has been introduced in version 0.25

Python specific notes:
The object exposes a readable attribute 'category'. This is the getter.

category=

Signature: void **category=** (string cat)

Description: Sets the category string of the annotation

The category string is an arbitrary string that can be used by various consumers or generators to mark 'their' annotation.

This method has been introduced in version 0.25

Python specific notes:
The object exposes a writable attribute 'category'. This is the setter.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

delete

Signature: void **delete**

Description: Deletes this annotation from the view

If the annotation is an "active" one, this method will remove it from the view. This object will become detached and can still be manipulated, but without having an effect on the view. This method has been introduced in version 0.25.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

detach

Signature: void **detach**

Description: Detaches the annotation object from the view

If the annotation object was inserted into the view, property changes will be reflected in the view. To disable this feature, 'detach' can be called after which the annotation object becomes inactive and changes will no longer be reflected in the view.

This method has been introduced in version 0.25.

dup

Signature: *[const]* new Annotation ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

fmt

Signature: *[const]* string **fmt**

Description: Returns the format used for the label

Returns: The format string

Format strings can contain placeholders for values and formulas for computing derived values. See Ruler properties for more details.

Python specific notes:
The object exposes a readable attribute 'fmt'. This is the getter.

fmt=

Signature: void **fmt=** (string format)

Description: Sets the format used for the label

format: The format string

Format strings can contain placeholders for values and formulas for computing derived values. See Ruler properties for more details.

Python specific notes:
The object exposes a writable attribute 'fmt'. This is the setter.

fmt_x

Signature: *[const]* string **fmt_x**

Description: Returns the format used for the x-axis label

Returns: The format string

Format strings can contain placeholders for values and formulas for computing derived values. See Ruler properties for more details.

Python specific notes:
The object exposes a readable attribute 'fmt_x'. This is the getter.

fmt_x=

Signature: void **fmt_x=** (string format)

Description: Sets the format used for the x-axis label

format: The format string

X-axis labels are only used for styles that have a horizontal component. Format strings can contain placeholders for values and formulas for computing derived values. See Ruler properties for more details.

Python specific notes:

The object exposes a writable attribute 'fmt_x'. This is the setter.

fmt_y

Signature: *[const]* string **fmt_y**

Description: Returns the format used for the y-axis label

Returns: The format string

Format strings can contain placeholders for values and formulas for computing derived values. See Ruler properties for more details.

Python specific notes:
The object exposes a readable attribute 'fmt_y'. This is the getter.

fmt_y=

Signature: void **fmt_y=** (string format)

Description: Sets the format used for the y-axis label

format: The format string

Y-axis labels are only used for styles that have a vertical component. Format strings can contain placeholders for values and formulas for computing derived values. See Ruler properties for more details.

Python specific notes:
The object exposes a writable attribute 'fmt_y'. This is the setter.

from_s

Signature: *[static]* new Annotation ptr **from_s** (string s)

Description: Creates a ruler from a string representation

This function creates a ruler from the string returned by to_s.

This method was introduced in version 0.28.

id

Signature: *[const]* int **id**

Description: Returns the annotation's ID

The annotation ID is an integer that uniquely identifies an annotation inside a view. The ID is used for replacing an annotation (see LayoutView#replace_annotation).

This method was introduced in version 0.24.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_valid?

Signature: *[const]* bool **is_valid?**

Description: Returns a value indicating whether the object is a valid reference.

If this value is true, the object represents an annotation on the screen. Otherwise, the object is a 'detached' annotation which does not have a representation on the screen.

This method was introduced in version 0.25.

main_position

Signature: *[const]* int **main_position**

Description: Gets the position of the main label

See main_position= for details.

This method has been introduced in version 0.25

Python specific notes:
The object exposes a readable attribute 'main_position'. This is the getter.

main_position=

Signature: void **main_position=** (int pos)

Description: Sets the position of the main label

This method accepts one of the Position... constants.

This method has been introduced in version 0.25

Python specific notes:
The object exposes a writable attribute 'main_position'. This is the setter.

main_xalign

Signature: *[const]* int **main_xalign**

Description: Gets the horizontal alignment type of the main label

See main_xalign= for details.

This method has been introduced in version 0.25

Python specific notes:
The object exposes a readable attribute 'main_xalign'. This is the getter.

main_xalign=

Signature: void **main_xalign=** (int align)

Description: Sets the horizontal alignment type of the main label

This method accepts one of the Align... constants.

This method has been introduced in version 0.25

Python specific notes:
The object exposes a writable attribute 'main_xalign'. This is the setter.

main_yalign

Signature: *[const]* int **main_yalign**

Description: Gets the vertical alignment type of the main label

See main_yalign= for details.

This method has been introduced in version 0.25

Python specific notes:
The object exposes a readable attribute 'main_yalign'. This is the getter.

main_yalign=

Signature: void **main_yalign=** (int align)

Description: Sets the vertical alignment type of the main label

This method accepts one of the Align... constants.

This method has been introduced in version 0.25

Python specific notes:
The object exposes a writable attribute 'main_yalign'. This is the setter.

new

Signature: *[static]* new Annotation ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

outline

Signature: *[const]* int **outline**

Description: Returns the outline style of the annotation object

Python specific notes:

The object exposes a readable attribute 'outline'. This is the getter.

outline=

Signature: void **outline=** (int outline)

Description: Sets the outline style used for drawing the annotation object

The Outline... values can be used for defining the annotation object's outline. The outline style determines what components are drawn.

Python specific notes:
The object exposes a writable attribute 'outline'. This is the setter.

p1

Signature: *[const]* DPoint **p1**

Description: Gets the first point of the ruler or marker

Returns: The first point

The points of the ruler or marker are always given in micron units in floating-point coordinates.

This method is provided for backward compatibility. Starting with version 0.28, rulers can be multi-segmented. Use points or seg_p1 to retrieve the points of the ruler segments.

Python specific notes:
The object exposes a readable attribute 'p1'. This is the getter.

p1=

Signature: void **p1=** (const DPoint point)

Description: Sets the first point of the ruler or marker

The points of the ruler or marker are always given in micron units in floating-point coordinates.

This method is provided for backward compatibility. Starting with version 0.28, rulers can be multi-segmented. Use points= to specify the ruler segments.

Python specific notes:
The object exposes a writable attribute 'p1'. This is the setter.

p2

Signature: *[const]* DPoint **p2**

Description: Gets the second point of the ruler or marker

Returns: The second point

The points of the ruler or marker are always given in micron units in floating-point coordinates.

This method is provided for backward compatibility. Starting with version 0.28, rulers can be multi-segmented. Use points or seg_p1 to retrieve the points of the ruler segments.

Python specific notes:
The object exposes a readable attribute 'p2'. This is the getter.

p2=

Signature: void **p2=** (const DPoint point)

Description: Sets the second point of the ruler or marker

The points of the ruler or marker are always given in micron units in floating-point coordinates.

This method is provided for backward compatibility. Starting with version 0.28, rulers can be multi-segmented. Use points= to specify the ruler segments.

Python specific notes:
The object exposes a writable attribute 'p2'. This is the setter.

points

Signature: *[const]* DPoint[] **points**

Description: Gets the points of the ruler

A single-segmented ruler has two points. Rulers with more points have more segments correspondingly. Note that the point list may have one point only (single-point ruler) or may even be empty.

Use points= to set the segment points. Use segments to get the number of segments and seg_p1 and seg_p2 to get the first and second point of one segment.

Multi-segmented rulers have been introduced in version 0.28

Python specific notes:
The object exposes a readable attribute 'points'. This is the getter.

points=

Signature: void **points=** (DPoint[] points)

Description: Sets the points for a (potentially) multi-segmented ruler

See points for a description of multi-segmented rulers. The list of points passed to this method is cleaned from duplicates before being stored inside the ruler.

This method has been introduced in version 0.28.

Python specific notes:
The object exposes a writable attribute 'points'. This is the setter.

register_template

Signature: *[static]* void **register_template** (const Annotation annotation, string title, int mode = RulerModeNormal)

Description: Registers the given annotation as a template globally

title:	The title to use for the ruler template
mode:	The mode the ruler will be created in (see Ruler... constants)

@annotation The annotation to use for the template (positions are ignored)

In order to register a system template, the category string of the annotation has to be a unique and non-empty string. The annotation is added to the list of annotation templates and becomes available as a new template in the ruler drop-down menu.

The new annotation template is registered on all views.

NOTE: this setting is persisted and the the application configuration is updated.

This method has been added in version 0.25.

seg_p1

Signature: *[const]* DPoint **seg_p1** (unsigned long segment_index)

Description: Gets the first point of the given segment.

The segment is indicated by the segment index which is a number between 0 and segments-1.

This method has been introduced in version 0.28.

seg_p2

Signature: *[const]* DPoint **seg_p2** (unsigned long segment_index)

Description: Gets the second point of the given segment.

The segment is indicated by the segment index which is a number between 0 and segments-1. The second point of a segment is also the first point of the following segment if there is one.

This method has been introduced in version 0.28.

segments

Signature: *[const]* unsigned long **segments**

Description: Gets the number of segments.

This method returns the number of segments the ruler is made up. Even though the ruler can be one or even zero points, the number of segments is at least 1.

This method has been introduced in version 0.28.

snap=

Signature: void **snap=** (bool flag)

Description: Sets the 'snap to objects' attribute

If this attribute is set to true, the ruler or marker snaps to other objects when moved.

Python specific notes:
The object exposes a writable attribute 'snap'. This is the setter.

snap?

Signature: *[const]* bool **snap?**

Description: Returns the 'snap to objects' attribute

Python specific notes:
The object exposes a readable attribute 'snap'. This is the getter.

style

Signature: *[const]* int **style**

Description: Returns the style of the annotation object

Python specific notes:
The object exposes a readable attribute 'style'. This is the getter.

style=

Signature: void **style=** (int style)

Description: Sets the style used for drawing the annotation object

The Style... values can be used for defining the annotation object's style. The style determines if ticks or arrows are drawn.

Python specific notes:
The object exposes a writable attribute 'style'. This is the setter.

text

Signature: *[const]* string **text** (unsigned long index = 0)

Description: Returns the formatted text for the main label

The index parameter indicates which segment to use (0 is the first one). It has been added in version 0.28.

text_x

Signature: *[const]* string **text_x** (unsigned long index = 0)

Description: Returns the formatted text for the x-axis label

The index parameter indicates which segment to use (0 is the first one). It has been added in version 0.28.

text_y

Signature: *[const]* string **text_y** (unsigned long index = 0)

Description: Returns the formatted text for the y-axis label

The index parameter indicates which segment to use (0 is the first one). It has been added in version 0.28.

to_s

Signature: *[const]* string **to_s**

Description: Returns the string representation of the ruler

This method was introduced in version 0.19.

Python specific notes:
This method is also available as 'str(object)'.

transformed

(1) Signature: *[const]* Annotation **transformed** (const DTrans t)

Description: Transforms the ruler or marker with the given simple transformation

t: The transformation to apply

Returns: The transformed object

(2) Signature: *[const]* Annotation **transformed** (const DCplxTrans t)

Description: Transforms the ruler or marker with the given complex transformation

t: The magnifying transformation to apply

Returns: The transformed object

Starting with version 0.25, all overloads all available as 'transform'.

(3) Signature: *[const]* Annotation **transformed** (const ICplxTrans t)

Description: Transforms the ruler or marker with the given complex transformation

t: The magnifying transformation to apply

Returns: The transformed object (in this case an integer coordinate object)

This method has been introduced in version 0.18.

Starting with version 0.25, all overloads all available as 'transform'.

transformed_cplx

(1) Signature: *[const]* Annotation **transformed_cplx** (const DCplxTrans t)

Description: Transforms the ruler or marker with the given complex transformation

t: The magnifying transformation to apply

Returns: The transformed object

Use of this method is deprecated. Use transformed instead

Starting with version 0.25, all overloads all available as 'transform'.

(2) Signature: *[const]* Annotation **transformed_cplx** (const ICplxTrans t)

Description: Transforms the ruler or marker with the given complex transformation

t: The magnifying transformation to apply

Returns: The transformed object (in this case an integer coordinate object)

Use of this method is deprecated. Use transformed instead

This method has been introduced in version 0.18.

Starting with version 0.25, all overloads all available as 'transform'.

unregister_templates

Signature: *[static]* void **unregister_templates** (string category)

Description: Unregisters the template or templates with the given category string globally

This method will remove all templates with the given category string. If the category string is empty, all templates are removed.

NOTE: this setting is persisted and the the application configuration is updated.

This method has been added in version 0.28.

xlabel_xalign

Signature: *[const]* int **xlabel_xalign**

Description: Gets the horizontal alignment type of the x axis label

See xlabel_xalign= for details.

This method has been introduced in version 0.25

Python specific notes:
The object exposes a readable attribute 'xlabel_xalign'. This is the getter.

xlabel_xalign=

Signature: void **xlabel_xalign=** (int align)

Description: Sets the horizontal alignment type of the x axis label

This method accepts one of the Align... constants.

This method has been introduced in version 0.25

Python specific notes:
The object exposes a writable attribute 'xlabel_xalign'. This is the setter.

xlabel_yalign

Signature: *[const]* int **xlabel_yalign**

Description: Gets the vertical alignment type of the x axis label

See xlabel_yalign= for details.

This method has been introduced in version 0.25

Python specific notes:
The object exposes a readable attribute 'xlabel_yalign'. This is the getter.

xlabel_yalign=

Signature: void **xlabel_yalign=** (int align)

Description: Sets the vertical alignment type of the x axis label

This method accepts one of the Align... constants.

This method has been introduced in version 0.25

Python specific notes:
The object exposes a writable attribute 'xlabel_yalign'. This is the setter.

ylabel_xalign

Signature: *[const]* int **ylabel_xalign**

Description: Gets the horizontal alignment type of the y axis label

See ylabel_xalign= for details.

This method has been introduced in version 0.25

Python specific notes:
The object exposes a readable attribute 'ylabel_xalign'. This is the getter.

ylabel_xalign=

Signature: void **ylabel_xalign=** (int align)

Description: Sets the horizontal alignment type of the y axis label

This method accepts one of the Align... constants.

This method has been introduced in version 0.25

Python specific notes:
The object exposes a writable attribute 'ylabel_xalign'. This is the setter.

ylabel_yalign

Signature: *[const]* int **ylabel_yalign**

Description: Gets the vertical alignment type of the y axis label

See ylabel_yalign= for details.

This method has been introduced in version 0.25

Python specific notes:
The object exposes a readable attribute 'ylabel_yalign'. This is the getter.

ylabel_yalign=

Signature: void **ylabel_yalign=** (int align)

Description: Sets the vertical alignment type of the y axis label

This method accepts one of the Align... constants.

This method has been introduced in version 0.25

Python specific notes:
The object exposes a writable attribute 'ylabel_yalign'. This is the setter.

4.228. API reference - Class ImageDataMapping

Notation used in Ruby API documentation

Module: lay

Description: A structure describing the data mapping of an image object

Data mapping is the process of transforming the data into RGB pixel values. This implementation provides four adjustment steps: first, in the case of monochrome data, the data is converted to a RGB triplet using the color map. The default color map will copy the value to all channels rendering a gray scale. After having normalized the data to 0..1 cooresponding to the min_value and max_value settings of the image, a color channel-independent brightness and contrast adjustment is applied. Then, a per-channel multiplier (red_gain, green_gain, blue_gain) is applied. Finally, the gamma function is applied and the result converted into a 0..255 pixel value range and clipped.

Public constructors

new ImageDataMapping ptr	**new**	Create a new data mapping object with default settings

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**add_colormap_entry**	(double value, unsigned int color)	Add a colormap entry for this data mapping object.
	void	**add_colormap_entry**	(double value, unsigned int lcolor, unsigned int rcolor)	Add a colormap entry for this data mapping object.
	void	**assign**	(const ImageDataMapping other)	Assigns another object to self
[const]	double	**blue_gain**		The blue channel gain
	void	**blue_gain=**	(double blue_gain)	Set the blue_gain
[const]	double	**brightness**		The brightness value
	void	**brightness=**	(double brightness)	Set the brightness

	void	clear_colormap		The the color map of this data mapping object.
[const]	unsigned int	colormap_color	(unsigned long n)	Returns the color for a given color map entry.
[const]	unsigned int	colormap_lcolor	(unsigned long n)	Returns the left-side color for a given color map entry.
[const]	unsigned int	colormap_rcolor	(unsigned long n)	Returns the right-side color for a given color map entry.
[const]	double	colormap_value	(unsigned long n)	Returns the value for a given color map entry.
[const]	double	contrast		The contrast value
	void	contrast=	(double contrast)	Set the contrast
[const]	new ImageDataMapping ptr	dup		Creates a copy of self
[const]	double	gamma		The gamma value
	void	gamma=	(double gamma)	Set the gamma
[const]	double	green_gain		The green channel gain
	void	green_gain=	(double green_gain)	Set the green_gain
[const]	unsigned long	num_colormap_entries		Returns the current number of color map entries.
[const]	double	red_gain		The red channel gain
	void	red_gain=	(double red_gain)	Set the red_gain

Deprecated methods (protected, public, static, non-static and constructors)

	void	create	Use of this method is deprecated. Use _create instead
	void	destroy	Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	is_const_object?	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void _**create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

add_colormap_entry

(1) Signature: void **add_colormap_entry** (double value, unsigned int color)

Description: Add a colormap entry for this data mapping object.

value: The value at which the given color should be applied.

color: The color to apply (a 32 bit RGB value).

This settings establishes a color mapping for a given value in the monochrome channel. The color must be given as a 32 bit integer, where the lowest order byte describes the blue component (0 to 255), the second byte the green component and the third byte the red component, i.e. 0xff0000 is red and 0x0000ff is blue.

(2) Signature: void **add_colormap_entry** (double value, unsigned int lcolor, unsigned int rcolor)

Description: Add a colormap entry for this data mapping object.

value:	The value at which the given color should be applied.
lcolor:	The color to apply left of the value (a 32 bit RGB value).
rcolor:	The color to apply right of the value (a 32 bit RGB value).

This settings establishes a color mapping for a given value in the monochrome channel. The colors must be given as a 32 bit integer, where the lowest order byte describes the blue component (0 to 255), the second byte the green component and the third byte the red component, i.e. 0xff0000 is red and 0x0000ff is blue.

In contrast to the version with one color, this version allows specifying a color left and right of the value - i.e. a discontinuous step.

This variant has been introduced in version 0.27.

assign

Signature: void **assign** (const ImageDataMapping other)

Description: Assigns another object to self

blue_gain

Signature: *[const]* double **blue_gain**

Description: The blue channel gain

This value is the multiplier by which the blue channel is scaled after applying false color transformation and contrast/brightness/gamma.

1.0 is a neutral value. The gain should be >=0.0.

Python specific notes:
The object exposes a readable attribute 'blue_gain'. This is the getter.

blue_gain=

Signature: void **blue_gain=** (double blue_gain)

Description: Set the blue_gain

See blue_gain for a description of this property.

Python specific notes:
The object exposes a writable attribute 'blue_gain'. This is the setter.

brightness

Signature: *[const]* double **brightness**

Description: The brightness value

The brightness is a double value between roughly -1.0 and 1.0. Neutral (original) brightness is 0.0.

Python specific notes:
The object exposes a readable attribute 'brightness'. This is the getter.

brightness=

Signature: void **brightness=** (double brightness)

Description: Set the brightness

See brightness for a description of this property.

Python specific notes:
The object exposes a writable attribute 'brightness'. This is the setter.

clear_colormap

Signature: void **clear_colormap**

Description: The the color map of this data mapping object.

colormap_color

Signature: *[const]* unsigned int **colormap_color** (unsigned long n)

Description: Returns the color for a given color map entry.

n: The index of the entry (0..num_colormap_entries-1)

Returns: The color (see add_colormap_entry for a description).

NOTE: this version is deprecated and provided for backward compatibility. For discontinuous nodes this method delivers the left-sided color.

colormap_lcolor

Signature: *[const]* unsigned int **colormap_lcolor** (unsigned long n)

Description: Returns the left-side color for a given color map entry.

n: The index of the entry (0..num_colormap_entries-1)

Returns: The color (see add_colormap_entry for a description).

This method has been introduced in version 0.27.

colormap_rcolor

Signature: *[const]* unsigned int **colormap_rcolor** (unsigned long n)

Description: Returns the right-side color for a given color map entry.

n: The index of the entry (0..num_colormap_entries-1)

Returns: The color (see add_colormap_entry for a description).

This method has been introduced in version 0.27.

colormap_value

Signature: *[const]* double **colormap_value** (unsigned long n)

Description: Returns the value for a given color map entry.

n: The index of the entry (0..num_colormap_entries-1)

Returns: The value (see add_colormap_entry for a description).

contrast

Signature: *[const]* double **contrast**

Description: The contrast value

The contrast is a double value between roughly -1.0 and 1.0. Neutral (original) contrast is 0.0.

Python specific notes:
The object exposes a readable attribute 'contrast'. This is the getter.

contrast=

Signature: void **contrast=** (double contrast)

Description: Set the contrast

See contrast for a description of this property.

Python specific notes:
The object exposes a writable attribute 'contrast'. This is the setter.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new ImageDataMapping ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

gamma

Signature: *[const]* double **gamma**

Description: The gamma value

The gamma value allows one to adjust for non-linearities in the display chain and to enhance contrast. A value for linear intensity reproduction on the screen is roughly 0.5. The exact value depends on the monitor calibration. Values below 1.0 give a "softer" appearance while values above 1.0 give a "harder" appearance.

Python specific notes:
The object exposes a readable attribute 'gamma'. This is the getter.

gamma=

Signature: void **gamma=** (double gamma)

Description: Set the gamma

See gamma for a description of this property.

Python specific notes:
The object exposes a writable attribute 'gamma'. This is the setter.

green_gain

Signature: *[const]* double **green_gain**

Description: The green channel gain

This value is the multiplier by which the green channel is scaled after applying false color transformation and contrast/brightness/gamma.

1.0 is a neutral value. The gain should be >=0.0.

Python specific notes:
The object exposes a readable attribute 'green_gain'. This is the getter.

green_gain=

Signature: void **green_gain=** (double green_gain)

Description: Set the green_gain

See green_gain for a description of this property.

Python specific notes:

	The object exposes a writable attribute 'green_gain'. This is the setter.
is_const_object?	**Signature**: *[const]* bool **is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.
new	**Signature**: *[static]* new ImageDataMapping ptr **new** **Description**: Create a new data mapping object with default settings **Python specific notes:** This method is the default initializer of the object.
num_colormap_entries	**Signature**: *[const]* unsigned long **num_colormap_entries** **Description**: Returns the current number of color map entries. **Returns**: The number of entries.
red_gain	**Signature**: *[const]* double **red_gain** **Description**: The red channel gain This value is the multiplier by which the red channel is scaled after applying false color transformation and contrast/brightness/gamma. 1.0 is a neutral value. The gain should be >=0.0. **Python specific notes:** The object exposes a readable attribute 'red_gain'. This is the getter.
red_gain=	**Signature**: void **red_gain=** (double red_gain) **Description**: Set the red_gain See red_gain for a description of this property. **Python specific notes:** The object exposes a writable attribute 'red_gain'. This is the setter.

4.229. API reference - Class Image

Notation used in Ruby API documentation

Module: lay

Description: An image to be stored as a layout annotation

Class hierarchy: Image

Images can be put onto the layout canvas as annotations, along with rulers and markers. Images can be monochrome (represent scalar data) as well as color (represent color images). The display of images can be adjusted in various ways, i.e. color mapping (translation of scalar values to colors), geometrical transformations (including rotation by arbitrary angles) and similar. Images are always based on floating point data. The actual data range is not fixed and can be adjusted to the data set (i.e. 0..255 or -1..1). This gives a great flexibility when displaying data which is the result of some measurement or calculation for example. The basic parameters of an image are the width and height of the data set, the width and height of one pixel, the geometrical transformation to be applied, the data range (min_value to max_value) and the data mapping which is described by an own class, ImageDataMapping.

Starting with version 0.22, the basic transformation is a 3x3 matrix rather than the simple affine transformation. This matrix includes the pixel dimensions as well. One consequence of that is that the magnification part of the matrix and the pixel dimensions are no longer separated. That has certain consequences, i.e. setting an affine transformation with a magnification scales the pixel sizes as before but an affine transformation returned will no longer contain the pixel dimensions as magnification because it only supports isotropic scaling. For backward compatibility, the rotation center for the affine transformations while the default center and the center for matrix transformations is the image center.

As with version 0.25, images become 'live' objects. Changes to image properties will be reflected in the view automatically once the image object has been inserted into a view. Note that changes are not immediately reflected in the view, but are delayed until the view is refreshed. Hence, iterating the view's images will not render the same results than the image objects attached to the view. To ensure synchronization, call Image#update.

Public constructors

new Image ptr	**new**		Create a new image with the default attributes
new Image ptr	**new**	(string filename, const DCplxTrans trans = unity)	Constructor from a image file
new Image ptr	**new**	(const PixelBuffer pixels, const DCplxTrans trans = unity)	Constructor from a image pixel buffer
new Image ptr	**new**	(const QImage image, const DCplxTrans trans = unity)	Constructor from a image pixel buffer
new Image ptr	**new**	(unsigned long w, unsigned long h, double[] data)	Constructor for a monochrome image with the given pixel values
new Image ptr	**new**	(unsigned long w, unsigned long h, const DCplxTrans trans, double[] data)	Constructor for a monochrome image with the given pixel values
new Image ptr	**new**	(unsigned long w, unsigned long h, double[] red, double[] green, double[] blue)	Constructor for a color image with the given pixel values
new Image ptr	**new**	(unsigned long w, unsigned long h, const DCplxTrans trans,	Constructor for a color image with the given pixel values

double[] red,
double[] green,
double[] blue)

Public methods

	void	_assign	(const Image other)	Assigns another object to self
	void	_create		Ensures the C++ object is created
	void	_destroy		Explicitly destroys the object
[const]	bool	_destroyed?		Returns a value indicating whether the object was already destroyed
[const]	new Image ptr	_dup		Creates a copy of self
[const]	bool	_is_const_object?		Returns a value indicating whether the reference is a const reference
	void	_manage		Marks the object as managed by the script side.
	void	_unmanage		Marks the object as no longer owned by the script side.
	void	assign	(const Image other)	Assigns another object to self
[const]	DBox	box		Gets the bounding box of the image
	void	clear		Clears the image data (sets to 0 or black).
	double[]	data	(int channel = 0)	Gets the data array for a specific color channel
[const]	ImageDataMapping	data_mapping		Gets the data mapping
	void	data_mapping=	(const ImageDataMapping data_mapping)	Sets the data mapping object
	void	delete		Deletes this image from the view
	void	detach		Detaches the image object from the view
[const]	new Image ptr	dup		Creates a copy of self
[const]	string	filename		Gets the name of the file loaded of an empty string if not file is loaded
[const]	double	get_pixel	(unsigned long x, unsigned long y)	Gets one pixel (monochrome only)
[const]	double	get_pixel	(unsigned long x, unsigned long y,	Gets one pixel (monochrome and color)

			unsigned int component)	
[const]	unsigned long	**height**		Gets the height of the image in pixels
[const]	unsigned long	**id**		Gets the Id
[const]	bool	**is_color?**		Returns true, if the image is a color image
[const]	bool	**is_empty?**		Returns true, if the image does not contain any data (i.e. is default constructed)
[const]	bool	**is_valid?**		Returns a value indicating whether the object is a valid reference.
[const]	bool	**is_visible?**		Gets a flag indicating whether the image object is visible
[const]	bool	**mask**	(unsigned long x, unsigned long y)	Gets the mask for one pixel
	bool[]	**mask_data**		Gets the mask from a array of boolean values
	void	**mask_data=**	(bool[] mask_data)	Sets the mask from a array of boolean values
[const]	Matrix3d	**matrix**		Returns the pixel-to-micron transformation matrix
	void	**matrix=**	(const Matrix3d t)	Sets the transformation matrix
[const]	double	**max_value**		Sets the maximum value
	void	**max_value=**	(double v)	Gets the upper limit of the values in the data set
[const]	double	**min_value**		Gets the upper limit of the values in the data set
	void	**min_value=**	(double v)	Sets the minimum value
[const]	double	**pixel_height**		Gets the pixel height
	void	**pixel_height=**	(double h)	Sets the pixel height
[const]	double	**pixel_width**		Gets the pixel width
	void	**pixel_width=**	(double w)	Sets the pixel width
	void	**set_data**	(unsigned long w, unsigned long h, double[] d)	Writes the image data field (monochrome)
	void	**set_data**	(unsigned long w, unsigned long h, double[] r, double[] g, double[] b)	Writes the image data field (color)

	void	**set_mask**	(unsigned long x, unsigned long y, bool m)	Sets the mask for a pixel
	void	**set_pixel**	(unsigned long x, unsigned long y, double v)	Sets one pixel (monochrome)
	void	**set_pixel**	(unsigned long x, unsigned long y, double r, double g, double b)	Sets one pixel (color)
[const]	string	**to_s**		Converts the image to a string
[const]	DCplxTrans	**trans**		Returns the pixel-to-micron transformation
	void	**trans=**	(const DCplxTrans t)	Sets the transformation
[const]	Image	**transformed**	(const DTrans t)	Transforms the image with the given simple transformation
[const]	Image	**transformed**	(const Matrix3d t)	Transforms the image with the given matrix transformation
[const]	Image	**transformed**	(const DCplxTrans t)	Transforms the image with the given complex transformation
	void	**update**		Forces an update of the view
	void	**visible=**	(bool v)	Sets the visibility
[const]	unsigned long	**width**		Gets the width of the image in pixels
[const]	void	**write**	(string path)	Saves the image to KLayout's image format (.lyimg)
[const]	int	**z_position**		Gets the z position of the image
	void	**z_position=**	(int z)	Sets the z position of the image

Public static methods and constants

new Image ptr	**from_s**	(string s)	Creates an image from the string returned by to_s.
new Image ptr	**read**	(string path)	Loads the image from the given path.

Deprecated methods (protected, public, static, non-static and constructors)

void	**create**		Use of this method is deprecated. Use _create instead
void	**destroy**		Use of this method is deprecated. Use _destroy instead

[const]	bool	**destroyed?**		Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**		Use of this method is deprecated. Use _is_const_object? instead
[const]	Image	**transformed_cplx**	(const DCplxTrans t)	Use of this method is deprecated. Use transformed instead
[const]	Image	**transformed_matrix**	(const Matrix3d t)	Use of this method is deprecated. Use transformed instead

Detailed description

_assign

Signature: void **_assign** (const Image other)

Description: Assigns another object to self

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_dup

Signature: *[const]* new Image ptr **_dup**

Description: Creates a copy of self

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const Image other)

Description: Assigns another object to self

box

Signature: *[const]* DBox **box**

Description: Gets the bounding box of the image

Returns: The bounding box

clear

Signature: void **clear**

Description: Clears the image data (sets to 0 or black).

This method has been introduced in version 0.27.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

data

Signature: double[] **data** (int channel = 0)

Description: Gets the data array for a specific color channel

Returns an array of pixel values for the given channel. For a color image, channel 0 is green, channel 1 is red and channel 2 is blue. For a monochrome image, the channel is ignored.

For the format of the data see the constructor description.

This method has been introduced in version 0.27.

data_mapping

Signature: *[const]* ImageDataMapping **data_mapping**

Description: Gets the data mapping

Returns: The data mapping object

The data mapping describes the transformation of a pixel value (any double value) into pixel data which can be sent to the graphics cards for display. See ImageDataMapping for a more detailed description.

Python specific notes:
The object exposes a readable attribute 'data_mapping'. This is the getter.

data_mapping=

Signature: void **data_mapping=** (const ImageDataMapping data_mapping)

Description: Sets the data mapping object

The data mapping describes the transformation of a pixel value (any double value) into pixel data which can be sent to the graphics cards for display. See ImageDataMapping for a more detailed description.

Python specific notes:
The object exposes a writable attribute 'data_mapping'. This is the setter.

delete

Signature: void **delete**

Description: Deletes this image from the view

If the image is an "active" one, this method will remove it from the view. This object will become detached and can still be manipulated, but without having an effect on the view. This method has been introduced in version 0.25.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

detach

Signature: void **detach**

Description: Detaches the image object from the view

If the image object was inserted into the view, property changes will be reflected in the view. To disable this feature, 'detach" can be called after which the image object becomes inactive and changes will no longer be reflected in the view.

This method has been introduced in version 0.25.

dup

Signature: *[const]* new Image ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

filename

Signature: *[const]* string **filename**

Description: Gets the name of the file loaded of an empty string if not file is loaded

Returns: The file name (path)

from_s

Signature: *[static]* new Image ptr **from_s** (string s)

Description: Creates an image from the string returned by to_s.

This method has been introduced in version 0.27.

get_pixel

(1) Signature: *[const]* double **get_pixel** (unsigned long x, unsigned long y)

Description: Gets one pixel (monochrome only)

x: The x coordinate of the pixel (0..width()-1)

y: The y coordinate of the pixel (mathematical order: 0 is the lowest, 0..height()-1)

If x or y value exceeds the image bounds, this method returns 0.0. This method is valid for monochrome images only. For color images it will return 0.0 always. Use is_color? to decide whether the image is a color image or monochrome one.

(2) Signature: *[const]* double **get_pixel** (unsigned long x, unsigned long y, unsigned int component)

Description: Gets one pixel (monochrome and color)

x: The x coordinate of the pixel (0..width()-1)

y: The y coordinate of the pixel (mathematical order: 0 is the lowest, 0..height()-1)

component: 0 for red, 1 for green, 2 for blue.

If the component index, x or y value exceeds the image bounds, this method returns 0.0. For monochrome images, the component index is ignored.

height

Signature: *[const]* unsigned long **height**

Description: Gets the height of the image in pixels

Returns: The height in pixels

id

Signature: *[const]* unsigned long **id**

Description: Gets the Id

The Id is an arbitrary integer that can be used to track the evolution of an image object. The Id is not changed when the object is edited. On initialization, a unique Id is given to the object. The Id cannot be changed. This behaviour has been modified in version 0.20.

is_color?

Signature: *[const]* bool **is_color?**

Description: Returns true, if the image is a color image

Returns: True, if the image is a color image

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_empty?

Signature: *[const]* bool **is_empty?**

Description: Returns true, if the image does not contain any data (i.e. is default constructed)

Returns: True, if the image is empty

is_valid?

Signature: *[const]* bool **is_valid?**

Description: Returns a value indicating whether the object is a valid reference.

If this value is true, the object represents an image on the screen. Otherwise, the object is a 'detached' image which does not have a representation on the screen.

This method was introduced in version 0.25.

is_visible?

Signature: *[const]* bool **is_visible?**

Description: Gets a flag indicating whether the image object is visible

An image object can be made invisible by setting the visible property to false.

This method has been introduced in version 0.20.

Python specific notes:
The object exposes a readable attribute 'visible'. This is the getter.

mask

Signature: *[const]* bool **mask** (unsigned long x, unsigned long y)

Description: Gets the mask for one pixel

x:	The x coordinate of the pixel (0..width()-1)
y:	The y coordinate of the pixel (mathematical order: 0 is the lowest, 0..height()-1)
Returns:	false if the pixel is not drawn.

See set_mask for details about the mask.

This method has been introduced in version 0.23.

mask_data

Signature: bool[] **mask_data**

Description: Gets the mask from a array of boolean values

See set_mask_data for a description of the data field.

This method has been introduced in version 0.27.

Python specific notes:
The object exposes a readable attribute 'mask_data'. This is the getter.

mask_data=

Signature: void **mask_data=** (bool[] mask_data)

Description: Sets the mask from a array of boolean values

The order of the boolean values is line first, from bottom to top and left to right and is the same as the order in the data array.

This method has been introduced in version 0.27.

Python specific notes:
The object exposes a writable attribute 'mask_data'. This is the setter.

matrix

Signature: *[const]* Matrix3d **matrix**

Description: Returns the pixel-to-micron transformation matrix

This transformation matrix converts pixel coordinates (0,0 being the center and each pixel having the dimension of pixel_width and pixel_height) to micron coordinates. The coordinate of the pixel is the lower left corner of the pixel.

The matrix is more general than the transformation used before and supports shear and perspective transformation. This property replaces the trans property which is still functional, but deprecated.

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'matrix'. This is the getter.

matrix=

Signature: void **matrix=** (const Matrix3d t)

Description: Sets the transformation matrix

This transformation matrix converts pixel coordinates (0,0 being the center and each pixel having the dimension of pixel_width and pixel_height) to micron coordinates. The coordinate of the pixel is the lower left corner of the pixel.

The matrix is more general than the transformation used before and supports shear and perspective transformation. This property replaces the trans property which is still functional, but deprecated.

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a writable attribute 'matrix'. This is the setter.

max_value

Signature: *[const]* double **max_value**

Description: Sets the maximum value

See the max_value method for the description of the maximum value property.

Python specific notes:
The object exposes a readable attribute 'max_value'. This is the getter.

max_value=

Signature: void **max_value=** (double v)

Description: Gets the upper limit of the values in the data set

This value determines the upper end of the data mapping (i.e. white value etc.). It does not necessarily correspond to the maximum value of the data set but it must be larger than that.

Python specific notes:
The object exposes a writable attribute 'max_value'. This is the setter.

min_value

Signature: *[const]* double **min_value**

Description: Gets the upper limit of the values in the data set

This value determines the upper end of the data mapping (i.e. white value etc.). It does not necessarily correspond to the minimum value of the data set but it must be larger than that.

Python specific notes:
The object exposes a readable attribute 'min_value'. This is the getter.

min_value=

Signature: void **min_value=** (double v)

Description: Sets the minimum value

See min_value for the description of the minimum value property.

Python specific notes:
The object exposes a writable attribute 'min_value'. This is the setter.

new

(1) Signature: *[static]* new Image ptr **new**

Description: Create a new image with the default attributes

This will create an empty image without data and no particular pixel width or related. Use the read_file or set_data methods to set image properties and pixel values.

Python specific notes:

This method is the default initializer of the object.

(2) Signature: *[static]* new Image ptr **new** (string filename, const DCplxTrans trans = unity)

Description: Constructor from a image file

filename:	The path to the image file to load.
trans:	The transformation to apply to the image when displaying it.

This constructor creates an image object from a file (which can have any format supported by Qt) and a transformation. The image will originally be put to position 0,0 (lower left corner) and each pixel will have a size of 1. The transformation describes how to transform this image into micron space.

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new Image ptr **new** (const PixelBuffer pixels, const DCplxTrans trans = unity)

Description: Constructor from a image pixel buffer

filename:	The path to the image file to load.
trans:	The transformation to apply to the image when displaying it.

This constructor creates an image object from a pixel buffer object. This object holds RGB or mono image data similar to QImage, except it is available also when Qt is not available (e.g. inside the Python module).

The image will originally be put to position 0,0 (lower left corner) and each pixel will have a size of 1. The transformation describes how to transform this image into micron space.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new Image ptr **new** (const QImage image, const DCplxTrans trans = unity)

Description: Constructor from a image pixel buffer

filename:	The path to the image file to load.
trans:	The transformation to apply to the image when displaying it.

This constructor creates an image object from a pixel QImage object and uses RGB or mono image data to generate the image.

The image will originally be put to position 0,0 (lower left corner) and each pixel will have a size of 1. The transformation describes how to transform this image into micron space.

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new Image ptr **new** (unsigned long w, unsigned long h, double[] data)

Description: Constructor for a monochrome image with the given pixel values

w:	The width of the image
h:	The height of the image
d:	The data (see method description)

This constructor creates an image from the given pixel values. The values have to be organized line by line. Each line must consist of "w" values where the first value is the leftmost pixel. Note, that the rows are oriented in the mathematical sense (first one is the lowest) contrary to the common convention for image data. Initially the pixel width and height will be 1 micron and the data range will be 0 to 1.0 (black to white level). To adjust the data range use the min_value and max_value properties.

Python specific notes:

This method is the default initializer of the object.

(6) Signature: *[static]* new Image ptr **new** (unsigned long w, unsigned long h, const DCplxTrans trans, double[] data)

Description: Constructor for a monochrome image with the given pixel values

w:	The width of the image
h:	The height of the image
trans:	The transformation from pixel space to micron space
d:	The data (see method description)

This constructor creates an image from the given pixel values. The values have to be organized line by line. Each line must consist of "w" values where the first value is the leftmost pixel. Note, that the rows are oriented in the mathematical sense (first one is the lowest) contrary to the common convention for image data. Initially the pixel width and height will be 1 micron and the data range will be 0 to 1.0 (black to white level). To adjust the data range use the min_value and max_value properties.

Python specific notes:
This method is the default initializer of the object.

(7) Signature: *[static]* new Image ptr **new** (unsigned long w, unsigned long h, double[] red, double[] green, double[] blue)

Description: Constructor for a color image with the given pixel values

w:	The width of the image
h:	The height of the image
red:	The red channel data set which will become owned by the image
green:	The green channel data set which will become owned by the image
blue:	The blue channel data set which will become owned by the image

This constructor creates an image from the given pixel values. The values have to be organized line by line and separated by color channel. Each line must consist of "w" values where the first value is the leftmost pixel. Note, that the rows are oriented in the mathematical sense (first one is the lowest) contrary to the common convention for image data. Initially the pixel width and height will be 1 micron and the data range will be 0 to 1.0 (black to white level). To adjust the data range use the min_value and max_value properties.

Python specific notes:
This method is the default initializer of the object.

(8) Signature: *[static]* new Image ptr **new** (unsigned long w, unsigned long h, const DCplxTrans trans, double[] red, double[] green, double[] blue)

Description: Constructor for a color image with the given pixel values

w:	The width of the image
h:	The height of the image
trans:	The transformation from pixel space to micron space
red:	The red channel data set which will become owned by the image
green:	The green channel data set which will become owned by the image
blue:	The blue channel data set which will become owned by the image

This constructor creates an image from the given pixel values. The values have to be organized line by line and separated by color channel. Each line must consist of "w" values where the first value is

the leftmost pixel. Note, that the rows are oriented in the mathematical sense (first one is the lowest) contrary to the common convention for image data. Initially the pixel width and height will be 1 micron and the data range will be 0 to 1.0 (black to white level). To adjust the data range use the min_value and max_value properties.

Python specific notes:
This method is the default initializer of the object.

pixel_height

Signature: *[const]* double **pixel_height**

Description: Gets the pixel height

See pixel_height= for a description of that property.

Starting with version 0.22, this property is incorporated into the transformation matrix. This property is provided for convenience only.

Python specific notes:
The object exposes a readable attribute 'pixel_height'. This is the getter.

pixel_height=

Signature: void **pixel_height=** (double h)

Description: Sets the pixel height

The pixel height determines the height of on pixel in the original space which is transformed to micron space with the transformation.

Starting with version 0.22, this property is incorporated into the transformation matrix. This property is provided for convenience only.

Python specific notes:
The object exposes a writable attribute 'pixel_height'. This is the setter.

pixel_width

Signature: *[const]* double **pixel_width**

Description: Gets the pixel width

See pixel_width= for a description of that property.

Starting with version 0.22, this property is incorporated into the transformation matrix. This property is provided for convenience only.

Python specific notes:
The object exposes a readable attribute 'pixel_width'. This is the getter.

pixel_width=

Signature: void **pixel_width=** (double w)

Description: Sets the pixel width

The pixel width determines the width of on pixel in the original space which is transformed to micron space with the transformation.

Starting with version 0.22, this property is incorporated into the transformation matrix. This property is provided for convenience only.

Python specific notes:
The object exposes a writable attribute 'pixel_width'. This is the setter.

read

Signature: *[static]* new Image ptr **read** (string path)

Description: Loads the image from the given path.

This method expects the image file as a KLayout image format file (.lyimg). This is a XML-based format containing the image data plus placement and transformation information for the image placement. In addition, image manipulation parameters for false color display and color channel enhancement are embedded.

This method has been introduced in version 0.27.

set_data

(1) Signature: void **set_data** (unsigned long w, unsigned long h, double[] d)

Description: Writes the image data field (monochrome)

- **w**: The width of the new data
- **h**: The height of the new data
- **d**: The (monochrome) data to load into the image

See the constructor description for the data organisation in that field.

(2) Signature: void **set_data** (unsigned long w, unsigned long h, double[] r, double[] g, double[] b)

Description: Writes the image data field (color)

- **w**: The width of the new data
- **h**: The height of the new data
- **r**: The red channel data to load into the image
- **g**: The green channel data to load into the image
- **b**: The blue channel data to load into the image

See the constructor description for the data organisation in that field.

set_mask

Signature: void **set_mask** (unsigned long x, unsigned long y, bool m)

Description: Sets the mask for a pixel

- **x**: The x coordinate of the pixel (0..width()-1)
- **y**: The y coordinate of the pixel (mathematical order: 0 is the lowest, 0..height()-1)
- **m**: The mask

If the mask of a pixel is set to false, the pixel is not drawn. The default is true for all pixels.

This method has been introduced in version 0.23.

set_pixel

(1) Signature: void **set_pixel** (unsigned long x, unsigned long y, double v)

Description: Sets one pixel (monochrome)

- **x**: The x coordinate of the pixel (0..width()-1)
- **y**: The y coordinate of the pixel (mathematical order: 0 is the lowest, 0..height()-1)
- **v**: The value

If the component index, x or y value exceeds the image bounds of the image is a color image, this method does nothing.

(2) Signature: void **set_pixel** (unsigned long x, unsigned long y, double r, double g, double b)

Description: Sets one pixel (color)

- **x**: The x coordinate of the pixel (0..width()-1)
- **y**: The y coordinate of the pixel (mathematical order: 0 is the lowest, 0..height()-1)
- **red**: The red component
- **green**: The green component

blue: The blue component

If the component index, x or y value exceeds the image bounds of the image is not a color image, this method does nothing.

to_s

Signature: *[const]* string **to_s**

Description: Converts the image to a string

Returns: The string

The string returned can be used to create an image object using from_s.

Python specific notes:
This method is also available as 'str(object)'.

trans

Signature: *[const]* DCplxTrans **trans**

Description: Returns the pixel-to-micron transformation

This transformation converts pixel coordinates (0,0 being the lower left corner and each pixel having the dimension of pixel_width and pixel_height) to micron coordinates. The coordinate of the pixel is the lower left corner of the pixel.

The general property is matrix which also allows perspective and shear transformation. This property will only work, if the transformation does not include perspective or shear components. Therefore this property is deprecated. Please note that for backward compatibility, the rotation center is pixel 0,0 (lowest left one), while it is the image center for the matrix transformation.

Python specific notes:
The object exposes a readable attribute 'trans'. This is the getter.

trans=

Signature: void **trans=** (const DCplxTrans t)

Description: Sets the transformation

This transformation converts pixel coordinates (0,0 being the lower left corner and each pixel having the dimension of pixel_width and pixel_height) to micron coordinates. The coordinate of the pixel is the lower left corner of the pixel.

The general property is matrix which also allows perspective and shear transformation. Please note that for backward compatibility, the rotation center is pixel 0,0 (lowest left one), while it is the image center for the matrix transformation.

Python specific notes:
The object exposes a writable attribute 'trans'. This is the setter.

transformed

(1) Signature: *[const]* Image **transformed** (const DTrans t)

Description: Transforms the image with the given simple transformation

t: The transformation to apply

Returns: The transformed object

(2) Signature: *[const]* Image **transformed** (const Matrix3d t)

Description: Transforms the image with the given matrix transformation

t: The transformation to apply (a matrix)

Returns: The transformed object

This method has been introduced in version 0.22.

(3) Signature: *[const]* Image **transformed** (const DCplxTrans t)

Description: Transforms the image with the given complex transformation

t: The magnifying transformation to apply

Returns: The transformed object

transformed_cplx

Signature: *[const]* Image **transformed_cplx** (const DCplxTrans t)

Description: Transforms the image with the given complex transformation

t: The magnifying transformation to apply

Returns: The transformed object

Use of this method is deprecated. Use transformed instead

transformed_matrix

Signature: *[const]* Image **transformed_matrix** (const Matrix3d t)

Description: Transforms the image with the given matrix transformation

t: The transformation to apply (a matrix)

Returns: The transformed object

Use of this method is deprecated. Use transformed instead

This method has been introduced in version 0.22.

update

Signature: void **update**

Description: Forces an update of the view

Usually it is not required to call this method. The image object is automatically synchronized with the view's image objects. For performance reasons this update is delayed to collect multiple update requests. Calling 'update' will ensure immediate updates.

This method has been introduced in version 0.25.

visible=

Signature: void **visible=** (bool v)

Description: Sets the visibility

See the is_visible? method for a description of this property.

This method has been introduced in version 0.20.

Python specific notes:
The object exposes a writable attribute 'visible'. This is the setter.

width

Signature: *[const]* unsigned long **width**

Description: Gets the width of the image in pixels

Returns: The width in pixels

write

Signature: *[const]* void **write** (string path)

Description: Saves the image to KLayout's image format (.lyimg)

This method has been introduced in version 0.27.

z_position

Signature: *[const]* int **z_position**

Description: Gets the z position of the image

Images with a higher z position are painted in front of images with lower z position. The z value is an integer that controls the position relative to other images.

This method was introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'z_position'. This is the getter.

z_position=

Signature: void **z_position=** (int z)

Description: Sets the z position of the image

See z_position for details about the z position attribute.

This method was introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'z_position'. This is the setter.

4.230. API reference - Class HelpDialog

Notation used in Ruby API documentation

Module: lay

Description: The help dialog

Class hierarchy: HelpDialog » QDialog » QWidget » QObject

This class makes the help dialog available as an individual object.

This class has been added in version 0.25.

Public constructors

HelpDialog ptr	**new**	(bool modal)	Creates a new help dialog
HelpDialog ptr	**new**	(QWidget ptr parent, bool modal)	Creates a new help dialog

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**load**	(string url)	Loads the specified URL
	void	**search**	(string topic)	Issues a search on the specified topic

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

load

Signature: void **load** (string url)

Description: Loads the specified URL

This method will call the page with the given URL.

new

(1) Signature: *[static]* HelpDialog ptr **new** (bool modal)

Description: Creates a new help dialog

If the modal flag is true, the dialog will be shown as a modal window.

(2) Signature: *[static]* HelpDialog ptr **new** (QWidget ptr parent, bool modal)

Description: Creates a new help dialog

If the modal flag is true, the dialog will be shown as a modal window.

search

Signature: void **search** (string topic)

Description: Issues a search on the specified topic

This method will call the search page with the given topic.

4.231. API reference - Class HelpSource

Notation used in Ruby API documentation

Module: lay

Description: A BrowserSource implementation delivering the help text for the help dialog

Class hierarchy: HelpSource » BrowserSource

This class can be used together with a BrowserPanel or BrowserDialog object to implement custom help systems.

The basic URL's served by this class are: "int:/index.xml" for the index page and "int:/search.xml?string=..." for the search topic retrieval.

This class has been added in version 0.25.

Public methods

	void	**_assign**	(const HelpSource other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new HelpSource ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	QDomDocument	**get_dom**	(string path)	Reserved for internal use
[const]	variant	**get_option**	(string key)	Reserved for internal use
	string	**parent_of**	(string path)	Reserved internal use
	void	**scan**		Reserved internal use
	void	**set_option**	(string key, variant value)	Reserved for internal use
	string	**title_for**	(string path)	Reserved internal use
	string[]	**urls**		Reserved for internal use

Public static methods and constants

void	**create_index_file**	(string path)	Reserved internal use
new HelpSource ptr	**plain**		Reserved for internal use

Detailed description

_assign

Signature: void **_assign** (const HelpSource other)

Description: Assigns another object to self

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_dup

Signature: *[const]* new HelpSource ptr **_dup**

Description: Creates a copy of self

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

4.232. API reference - Class MainWindow

Notation used in Ruby API documentation

Module: lay

Description: The main application window and central controller object

Class hierarchy: MainWindow » QMainWindow » QWidget » QObject

This object first is the main window but also the main controller. The main controller is the port by which access can be gained to all the data objects, view and other aspects of the program.

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**call_menu**	(string symbol)	Calls the menu item with the provided symbol.
	void	**cancel**		Cancels current editing operations
	void	**clear_config**		Clears the configuration parameters
	void	**clone_current_view**		Clones the current view and make it current
	void	**close_all**		Closes all views
	void	**close_current_view**		Closes the current view
	void	**commit_config**		Commits the configuration settings
	CellView	**create_layout**	(int mode)	Creates a new, empty layout
	CellView	**create_layout**	(string tech, int mode)	Creates a new, empty layout with the given technology
	int	**create_view**		Creates a new, empty view
	LayoutView ptr	**current_view**		Returns a reference to the current view's object
[const]	int	**current_view_index**		Returns the current view's index
	void	**current_view_index=**	(int index)	Selects the view with the given index

[const]	Dispatcher ptr	**dispatcher**		Gets the dispatcher interface (the plugin root configuration space)
	void	**exit**		Schedules an exit for the application
	variant	**get_config**	(string name)	Gets the value of a local configuration parameter
	string[]	**get_config_names**		Gets the configuration parameter names
	map<string,string>	**get_default_key_bindings**		Gets the default key bindings
	map<string,bool>	**get_default_menu_items_h**		Gets the flags indicating whether menu items are hidden by default
	map<string,string>	**get_key_bindings**		Gets the current key bindings
	map<string,bool>	**get_menu_items_hidden**		Gets the flags indicating whether menu items are hidden
[const]	double	**grid_micron**		Gets the global grid in micron
[const]	int	**index_of**	(const LayoutView ptr view)	Gets the index of the given view
	string	**initial_technology**		Gets the technology used for creating or loading layouts (unless explicitly specified)
	void	**initial_technology=**	(string tech)	Sets the technology used for creating or loading layouts (unless explicitly specified)
	CellView	**load_layout**	(string filename, int mode = 1)	Loads a new layout
	CellView	**load_layout**	(string filename, string tech, int mode = 1)	Loads a new layout and associate it with the given technology
	CellView	**load_layout**	(string filename, const LoadLayoutOptions options, int mode = 1)	Loads a new layout with the given options
	CellView	**load_layout**	(string filename, const LoadLayoutOptions options, string tech, int mode = 1)	Loads a new layout with the given options and associate it with the given technology
	Manager	**manager**		Gets the Manager object of this window
	AbstractMenu ptr	**menu**		Returns a reference to the abstract menu
	void	**message**	(string message, int time = infinite)	Displays a message in the status bar

[signal]	void	on_current_view_changed		An event indicating that the current view has changed
[signal]	void	on_session_about_to_be_restored		An event indicating that a session is about to be restored
[signal]	void	on_session_restored		An event indicating that a session was restored
[signal]	void	on_view_closed	(int index)	An event indicating that a view was closed
[signal]	void	on_view_created	(int index)	An event indicating that a new view was created
	bool	read_config	(string file_name)	Reads the configuration from a file
	void	redraw		Redraws the current view
	void	resize	(int width, int height)	Resizes the window
	void	restore_session	(string fn)	Restores a session from the given file
	void	save_session	(string fn)	Saves the session to the given file
	void	set_config	(string name, string value)	Set a local configuration parameter with the given name to the given value
	void	set_key_bindings	(map<string,string> bindings)	Sets key bindings.
	void	set_menu_items_hidden	(map<string,bool> flags)	sets the flags indicating whether menu items are hidden
	void	show_macro_editor	(string cat = , bool add = false)	Shows the macro editor
[const]	bool	synchronous		Gets a value indicating whether synchronous mode is activated
	void	synchronous=	(bool sync_mode)	Puts the main window into synchronous mode
[const]	string	title		Gets the window title
	void	title=	(string title)	Sets the window title
	LayoutView ptr	view	(int n)	Returns a reference to a view object by index
[const]	unsigned int	views		Returns the number of views
	bool	write_config	(string file_name)	Writes configuration to a file

Public static methods and constants

MainWindow ptr	**instance**	Gets application's main window instance
string[]	**menu_symbols**	Gets all available menu symbols (see call_menu).

Deprecated methods (protected, public, static, non-static and constructors)

void	**cm_adjust_origin**	Use of this method is deprecated

void	cm_zoom_out		Use of this method is deprecated
void	enable_edits	(bool enable)	Use of this method is deprecated
void	select_view	(int index)	Use of this method is deprecated. Use current_view_index= instead
void	synchronous	(bool sync_mode)	Use of this method is deprecated. Use synchronous= instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

	After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required. Usually it's not required to call this method. It has been introduced in version 0.24.
_unmanage	**Signature**: void **_unmanage** **Description**: Marks the object as no longer owned by the script side. Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.
call_menu	**Signature**: void **call_menu** (string symbol) **Description**: Calls the menu item with the provided symbol. To obtain all symbols, use menu_symbols. This method has been introduced in version 0.27 and replaces the previous cm_... methods. Instead of calling a specific cm_... method, use LayoutView#call_menu with 'cm_...' as the symbol.
cancel	**Signature**: void **cancel** **Description**: Cancels current editing operations This method call cancels all current editing operations and restores normal mouse mode.
clear_config	**Signature**: void **clear_config** **Description**: Clears the configuration parameters This method is provided for using MainWindow without an Application object. It's a convience method which is equivalent to 'dispatcher().clear_config()'. See Dispatcher#clear_config for details. This method has been introduced in version 0.27.
clone_current_view	**Signature**: void **clone_current_view** **Description**: Clones the current view and make it current
close_all	**Signature**: void **close_all** **Description**: Closes all views This method unconditionally closes all views. No dialog will be opened if unsaved edits exist. This method was added in version 0.18.
close_current_view	**Signature**: void **close_current_view** **Description**: Closes the current view This method does not open a dialog to ask which cell view to close if multiple cells are opened in the view, but rather closes all cells.

cm_adjust_origin	**Signature**: void **cm_adjust_origin** **Description**: 'cm_adjust_origin' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_adjust_origin')" instead.
cm_bookmark_view	**Signature**: void **cm_bookmark_view** **Description**: 'cm_bookmark_view' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_bookmark_view')" instead.
cm_cancel	**Signature**: void **cm_cancel** **Description**: 'cm_cancel' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_cancel')" instead.
cm_cell_copy	**Signature**: void **cm_cell_copy** **Description**: 'cm_cell_copy' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_cell_copy')" instead.
cm_cell_cut	**Signature**: void **cm_cell_cut** **Description**: 'cm_cell_cut' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_cell_cut')" instead.
cm_cell_delete	**Signature**: void **cm_cell_delete** **Description**: 'cm_cell_delete' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_cell_delete')" instead.
cm_cell_flatten	**Signature**: void **cm_cell_flatten** **Description**: 'cm_cell_flatten' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_cell_flatten')" instead.
cm_cell_hide	**Signature**: void **cm_cell_hide** **Description**: 'cm_cell_hide' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_cell_hide')" instead.
cm_cell_paste	**Signature**: void **cm_cell_paste** **Description**: 'cm_cell_paste' action. Use of this method is deprecated

	This method is deprecated in version 0.27. Use "call_menu('cm_cell_paste')" instead.
cm_cell_rename	**Signature**: void **cm_cell_rename** **Description**: 'cm_cell_rename' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_cell_rename')" instead.
cm_cell_select	**Signature**: void **cm_cell_select** **Description**: 'cm_cell_select' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_cell_select')" instead.
cm_cell_show	**Signature**: void **cm_cell_show** **Description**: 'cm_cell_show' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_cell_show')" instead.
cm_cell_show_all	**Signature**: void **cm_cell_show_all** **Description**: 'cm_cell_show_all' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_cell_show_all')" instead.
cm_clear_layer	**Signature**: void **cm_clear_layer** **Description**: 'cm_clear_layer' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_clear_layer')" instead.
cm_clone	**Signature**: void **cm_clone** **Description**: 'cm_clone' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_clone')" instead.
cm_close	**Signature**: void **cm_close** **Description**: 'cm_close' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_close')" instead.
cm_close_all	**Signature**: void **cm_close_all** **Description**: 'cm_close_all' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_close_all')" instead.
cm_copy	**Signature**: void **cm_copy** **Description**: 'cm_copy' action.

	Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_copy')" instead.
cm_copy_layer	**Signature**: void **cm_copy_layer** **Description**: 'cm_copy_layer' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_copy_layer')" instead.
cm_cut	**Signature**: void **cm_cut** **Description**: 'cm_cut' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_cut')" instead.
cm_dec_max_hier	**Signature**: void **cm_dec_max_hier** **Description**: 'cm_dec_max_hier' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_dec_max_hier')" instead.
cm_delete	**Signature**: void **cm_delete** **Description**: 'cm_delete' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_delete')" instead.
cm_delete_layer	**Signature**: void **cm_delete_layer** **Description**: 'cm_delete_layer' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_delete_layer')" instead.
cm_edit_layer	**Signature**: void **cm_edit_layer** **Description**: 'cm_edit_layer' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_edit_layer')" instead.
cm_exit	**Signature**: void **cm_exit** **Description**: 'cm_exit' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_exit')" instead.
cm_goto_position	**Signature**: void **cm_goto_position** **Description**: 'cm_goto_position' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_goto_position')" instead.

cm_help_about	**Signature**: void **cm_help_about** **Description**: 'cm_help_about' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_help_about')" instead.
cm_inc_max_hier	**Signature**: void **cm_inc_max_hier** **Description**: 'cm_inc_max_hier' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_inc_max_hier')" instead.
cm_last_display_state	**Signature**: void **cm_last_display_state** **Description**: 'cm_prev_display_state|#cm_last_display_state' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_prev_display_state|#cm_last_display_state')" instead.
cm_layout_props	**Signature**: void **cm_layout_props** **Description**: 'cm_layout_props' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_layout_props')" instead.
cm_load_bookmarks	**Signature**: void **cm_load_bookmarks** **Description**: 'cm_load_bookmarks' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_load_bookmarks')" instead.
cm_load_layer_props	**Signature**: void **cm_load_layer_props** **Description**: 'cm_load_layer_props' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_load_layer_props')" instead.
cm_lv_add_missing	**Signature**: void **cm_lv_add_missing** **Description**: 'cm_lv_add_missing' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_add_missing')" instead.
cm_lv_delete	**Signature**: void **cm_lv_delete** **Description**: 'cm_lv_delete' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_delete')" instead.
cm_lv_expand_all	**Signature**: void **cm_lv_expand_all** **Description**: 'cm_lv_expand_all' action.

	Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_expand_all')" instead.
cm_lv_group	**Signature**: void **cm_lv_group** **Description**: 'cm_lv_group' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_group')" instead.
cm_lv_hide	**Signature**: void **cm_lv_hide** **Description**: 'cm_lv_hide' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_hide')" instead.
cm_lv_hide_all	**Signature**: void **cm_lv_hide_all** **Description**: 'cm_lv_hide_all' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_hide_all')" instead.
cm_lv_insert	**Signature**: void **cm_lv_insert** **Description**: 'cm_lv_insert' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_insert')" instead.
cm_lv_new_tab	**Signature**: void **cm_lv_new_tab** **Description**: 'cm_lv_new_tab' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_new_tab')" instead.
cm_lv_regroup_by_datatype	**Signature**: void **cm_lv_regroup_by_datatype** **Description**: 'cm_lv_regroup_by_datatype' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_regroup_by_datatype')" instead.
cm_lv_regroup_by_index	**Signature**: void **cm_lv_regroup_by_index** **Description**: 'cm_lv_regroup_by_index' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_regroup_by_index')" instead.
cm_lv_regroup_by_layer	**Signature**: void **cm_lv_regroup_by_layer** **Description**: 'cm_lv_regroup_by_layer' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_regroup_by_layer')" instead.

cm_lv_regroup_flatten	**Signature**: void **cm_lv_regroup_flatten** **Description**: 'cm_lv_regroup_flatten' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_regroup_flatten')" instead.
cm_lv_remove_tab	**Signature**: void **cm_lv_remove_tab** **Description**: 'cm_lv_remove_tab' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_remove_tab')" instead.
cm_lv_remove_unused	**Signature**: void **cm_lv_remove_unused** **Description**: 'cm_lv_remove_unused' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_remove_unused')" instead.
cm_lv_rename	**Signature**: void **cm_lv_rename** **Description**: 'cm_lv_rename' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_rename')" instead.
cm_lv_rename_tab	**Signature**: void **cm_lv_rename_tab** **Description**: 'cm_lv_rename_tab' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_rename_tab')" instead.
cm_lv_select_all	**Signature**: void **cm_lv_select_all** **Description**: 'cm_lv_select_all' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_select_all')" instead.
cm_lv_show	**Signature**: void **cm_lv_show** **Description**: 'cm_lv_show' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_show')" instead.
cm_lv_show_all	**Signature**: void **cm_lv_show_all** **Description**: 'cm_lv_show_all' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_show_all')" instead.
cm_lv_show_only	**Signature**: void **cm_lv_show_only** **Description**: 'cm_lv_show_only' action. Use of this method is deprecated

	This method is deprecated in version 0.27. Use "call_menu('cm_lv_show_only')" instead.
cm_lv_sort_by_dli	**Signature**: void **cm_lv_sort_by_dli** **Description**: 'cm_lv_sort_by_dli' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_sort_by_dli')" instead.
cm_lv_sort_by_idl	**Signature**: void **cm_lv_sort_by_idl** **Description**: 'cm_lv_sort_by_idl' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_sort_by_idl')" instead.
cm_lv_sort_by_ild	**Signature**: void **cm_lv_sort_by_ild** **Description**: 'cm_lv_sort_by_ild' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_sort_by_ild')" instead.
cm_lv_sort_by_ldi	**Signature**: void **cm_lv_sort_by_ldi** **Description**: 'cm_lv_sort_by_ldi' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_sort_by_ldi')" instead.
cm_lv_sort_by_name	**Signature**: void **cm_lv_sort_by_name** **Description**: 'cm_lv_sort_by_name' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_sort_by_name')" instead.
cm_lv_source	**Signature**: void **cm_lv_source** **Description**: 'cm_lv_source' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_source')" instead.
cm_lv_ungroup	**Signature**: void **cm_lv_ungroup** **Description**: 'cm_lv_ungroup' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_lv_ungroup')" instead.
cm_macro_editor	**Signature**: void **cm_macro_editor** **Description**: 'cm_macro_editor' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_macro_editor')" instead.
cm_manage_bookmarks	**Signature**: void **cm_manage_bookmarks** **Description**: 'cm_manage_bookmarks' action.

	Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_manage_bookmarks')" instead.
cm_max_hier	**Signature**: void **cm_max_hier** **Description**: 'cm_max_hier' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_max_hier')" instead.
cm_max_hier_0	**Signature**: void **cm_max_hier_0** **Description**: 'cm_max_hier_0' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_max_hier_0')" instead.
cm_max_hier_1	**Signature**: void **cm_max_hier_1** **Description**: 'cm_max_hier_1' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_max_hier_1')" instead.
cm_navigator_close	**Signature**: void **cm_navigator_close** **Description**: 'cm_navigator_close' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_navigator_close')" instead.
cm_new_cell	**Signature**: void **cm_new_cell** **Description**: 'cm_new_cell' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_new_cell')" instead.
cm_new_layer	**Signature**: void **cm_new_layer** **Description**: 'cm_new_layer' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_new_layer')" instead.
cm_new_layout	**Signature**: void **cm_new_layout** **Description**: 'cm_new_layout' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_new_layout')" instead.
cm_new_panel	**Signature**: void **cm_new_panel** **Description**: 'cm_new_panel' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_new_panel')" instead.

cm_next_display_state	**Signature**: void **cm_next_display_state** **Description**: 'cm_next_display_state' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_next_display_state')" instead.
cm_open	**Signature**: void **cm_open** **Description**: 'cm_open' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_open')" instead.
cm_open_current_cell	**Signature**: void **cm_open_current_cell** **Description**: 'cm_open_current_cell' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_open_current_cell')" instead.
cm_open_new_view	**Signature**: void **cm_open_new_view** **Description**: 'cm_open_new_view' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_open_new_view')" instead.
cm_open_too	**Signature**: void **cm_open_too** **Description**: 'cm_open_too' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_open_too')" instead.
cm_packages	**Signature**: void **cm_packages** **Description**: 'cm_packages' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_packages')" instead.
cm_pan_down	**Signature**: void **cm_pan_down** **Description**: 'cm_pan_down' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_pan_down')" instead.
cm_pan_left	**Signature**: void **cm_pan_left** **Description**: 'cm_pan_left' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_pan_left')" instead.
cm_pan_right	**Signature**: void **cm_pan_right** **Description**: 'cm_pan_right' action. Use of this method is deprecated

	This method is deprecated in version 0.27. Use "call_menu('cm_pan_right')" instead.
cm_pan_up	**Signature**: void **cm_pan_up** **Description**: 'cm_pan_up' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_pan_up')" instead.
cm_paste	**Signature**: void **cm_paste** **Description**: 'cm_paste' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_paste')" instead.
cm_prev_display_state	**Signature**: void **cm_prev_display_state** **Description**: 'cm_prev_display_state|#cm_last_display_state' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_prev_display_state|#cm_last_display_state')" instead.
cm_print	**Signature**: void **cm_print** **Description**: 'cm_print' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_print')" instead.
cm_pull_in	**Signature**: void **cm_pull_in** **Description**: 'cm_pull_in' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_pull_in')" instead.
cm_reader_options	**Signature**: void **cm_reader_options** **Description**: 'cm_reader_options' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_reader_options')" instead.
cm_redo	**Signature**: void **cm_redo** **Description**: 'cm_redo' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_redo')" instead.
cm_redraw	**Signature**: void **cm_redraw** **Description**: 'cm_redraw' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_redraw')" instead.

cm_reload	**Signature**: void **cm_reload** **Description**: 'cm_reload' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_reload')" instead.
cm_reset_window_state	**Signature**: void **cm_reset_window_state** **Description**: 'cm_reset_window_state' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_reset_window_state')" instead.
cm_restore_session	**Signature**: void **cm_restore_session** **Description**: 'cm_restore_session' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_restore_session')" instead.
cm_save	**Signature**: void **cm_save** **Description**: 'cm_save' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_save')" instead.
cm_save_all	**Signature**: void **cm_save_all** **Description**: 'cm_save_all' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_save_all')" instead.
cm_save_as	**Signature**: void **cm_save_as** **Description**: 'cm_save_as' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_save_as')" instead.
cm_save_bookmarks	**Signature**: void **cm_save_bookmarks** **Description**: 'cm_save_bookmarks' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_save_bookmarks')" instead.
cm_save_current_cell_as	**Signature**: void **cm_save_current_cell_as** **Description**: 'cm_save_current_cell_as' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_save_current_cell_as')" instead.
cm_save_layer_props	**Signature**: void **cm_save_layer_props** **Description**: 'cm_save_layer_props' action. Use of this method is deprecated

	This method is deprecated in version 0.27. Use "call_menu('cm_save_layer_props')" instead.
cm_save_session	**Signature**: void **cm_save_session** **Description**: 'cm_save_session' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_save_session')" instead.
cm_screenshot	**Signature**: void **cm_screenshot** **Description**: 'cm_screenshot' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_screenshot')" instead.
cm_screenshot_to_clipboard	**Signature**: void **cm_screenshot_to_clipboard** **Description**: 'cm_screenshot_to_clipboard' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_screenshot_to_clipboard')" instead.
cm_sel_flip_x	**Signature**: void **cm_sel_flip_x** **Description**: 'cm_sel_flip_x' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_sel_flip_x')" instead.
cm_sel_flip_y	**Signature**: void **cm_sel_flip_y** **Description**: 'cm_sel_flip_y' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_sel_flip_y')" instead.
cm_sel_free_rot	**Signature**: void **cm_sel_free_rot** **Description**: 'cm_sel_free_rot' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_sel_free_rot')" instead.
cm_sel_move	**Signature**: void **cm_sel_move** **Description**: 'cm_sel_move' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_sel_move')" instead.
cm_sel_move_to	**Signature**: void **cm_sel_move_to** **Description**: 'cm_sel_move_to' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_sel_move_to')" instead.

cm_sel_rot_ccw	**Signature**: void **cm_sel_rot_ccw** **Description**: 'cm_sel_rot_ccw' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_sel_rot_ccw')" instead.
cm_sel_rot_cw	**Signature**: void **cm_sel_rot_cw** **Description**: 'cm_sel_rot_cw' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_sel_rot_cw')" instead.
cm_sel_scale	**Signature**: void **cm_sel_scale** **Description**: 'cm_sel_scale' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_sel_scale')" instead.
cm_select_all	**Signature**: void **cm_select_all** **Description**: 'cm_select_all' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_select_all')" instead.
cm_select_cell	**Signature**: void **cm_select_cell** **Description**: 'cm_select_cell' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_select_cell')" instead.
cm_select_current_cell	**Signature**: void **cm_select_current_cell** **Description**: 'cm_select_current_cell' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_select_current_cell')" instead.
cm_setup	**Signature**: void **cm_setup** **Description**: 'cm_setup' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_setup')" instead.
cm_show_properties	**Signature**: void **cm_show_properties** **Description**: 'cm_show_properties' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_show_properties')" instead.
cm_technologies	**Signature**: void **cm_technologies** **Description**: 'cm_technologies' action. Use of this method is deprecated

	This method is deprecated in version 0.27. Use "call_menu('cm_technologies')" instead.
cm_undo	**Signature**: void **cm_undo** **Description**: 'cm_undo' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_undo')" instead.
cm_unselect_all	**Signature**: void **cm_unselect_all** **Description**: 'cm_unselect_all' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_unselect_all')" instead.
cm_view_log	**Signature**: void **cm_view_log** **Description**: 'cm_view_log' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_view_log')" instead.
cm_zoom_fit	**Signature**: void **cm_zoom_fit** **Description**: 'cm_zoom_fit' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_zoom_fit')" instead.
cm_zoom_fit_sel	**Signature**: void **cm_zoom_fit_sel** **Description**: 'cm_zoom_fit_sel' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_zoom_fit_sel')" instead.
cm_zoom_in	**Signature**: void **cm_zoom_in** **Description**: 'cm_zoom_in' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_zoom_in')" instead.
cm_zoom_out	**Signature**: void **cm_zoom_out** **Description**: 'cm_zoom_out' action. Use of this method is deprecated This method is deprecated in version 0.27. Use "call_menu('cm_zoom_out')" instead.
commit_config	**Signature**: void **commit_config** **Description**: Commits the configuration settings This method is provided for using MainWindow without an Application object. It's a convience method which is equivalent to 'dispatcher().commit_config(...)'. See Dispatcher#commit_config for details. This method has been introduced in version 0.27.

create_layout

(1) Signature: CellView **create_layout** (int mode)

Description: Creates a new, empty layout

mode: An integer value of 0, 1 or 2 that determines how the layout is created

Returns: The cellview of the layout that was created

Create the layout in the current view, replacing the current layouts (mode 0), in a new view (mode 1) or adding it to the current view (mode 2). In mode 1, the new view is made the current one.

This version uses the initial technology and associates it with the new layout.

Starting with version 0.25, this method returns a cellview object that can be modified to configure the cellview.

(2) Signature: CellView **create_layout** (string tech, int mode)

Description: Creates a new, empty layout with the given technology

mode: An integer value of 0, 1 or 2 that determines how the layout is created

tech: The name of the technology to use for that layout.

Returns: The cellview of the layout that was created

Create the layout in the current view, replacing the current layouts (mode 0), in a new view (mode 1) or adding it to the current view (mode 2). In mode 1, the new view is made the current one.

If the technology name is not a valid technology name, the default technology will be used.

This version was introduced in version 0.22. Starting with version 0.25, this method returns a cellview object that can be modified to configure the cellview.

create_view

Signature: int **create_view**

Description: Creates a new, empty view

Returns: The index of the view that was created

Creates an empty view that can be filled with layouts using the load_layout and create_layout methods on the view object. Use the view method to obtain the view object from the view index. This method has been added in version 0.22.

current_view

Signature: LayoutView ptr **current_view**

Description: Returns a reference to the current view's object

Returns: A reference to a LayoutView object representing the current view.

current_view_index

Signature: *[const]* int **current_view_index**

Description: Returns the current view's index

Returns: The index of the current view

This method will return the index of the current view.

Python specific notes:
The object exposes a readable attribute 'current_view_index'. This is the getter.

current_view_index=

Signature: void **current_view_index=** (int index)

Description: Selects the view with the given index

index: The index of the view to select (0 is the first)

This method will make the view with the given index the current (front) view.

This method was renamed from select_view to current_view_index= in version 0.25. The old name is still available, but deprecated.

Python specific notes:
The object exposes a writable attribute 'current_view_index'. This is the setter.

dispatcher

Signature: *[const]* Dispatcher ptr **dispatcher**

Description: Gets the dispatcher interface (the plugin root configuration space)

This method has been introduced in version 0.27.

enable_edits

Signature: void **enable_edits** (bool enable)

Description: Enables or disables editing

enable: Enable edits if set to true

Use of this method is deprecated

Starting from version 0.25, this method enables/disables edits on the current view only. Use LayoutView#enable_edits instead.

exit

Signature: void **exit**

Description: Schedules an exit for the application

This method does not immediately exit the application but sends an exit request to the application which will cause a clean shutdown of the GUI.

get_config

Signature: variant **get_config** (string name)

Description: Gets the value of a local configuration parameter

This method is provided for using MainWindow without an Application object. It's a convience method which is equivalent to 'dispatcher().get_config(...)'. See Dispatcher#get_config for details.

This method has been introduced in version 0.27.

get_config_names

Signature: string[] **get_config_names**

Description: Gets the configuration parameter names

This method is provided for using MainWindow without an Application object. It's a convience method which is equivalent to 'dispatcher().get_config_names(...)'. See Dispatcher#get_config_names for details.

This method has been introduced in version 0.27.

get_default_key_bindings

Signature: map<string,string> **get_default_key_bindings**

Description: Gets the default key bindings

This method returns a hash with the default key binding vs. menu item path. You can use this hash with set_key_bindings to reset all key bindings to the default ones.

This method has been introduced in version 0.27.

get_default_menu_items_hidden

Signature: map<string,bool> **get_default_menu_items_hidden**

Description: Gets the flags indicating whether menu items are hidden by default

You can use this hash with set_menu_items_hidden to restore the visibility of all menu items.

This method has been introduced in version 0.27.

get_key_bindings

Signature: map<string,string> **get_key_bindings**

Description: Gets the current key bindings

This method returns a hash with the key binding vs. menu item path.

This method has been introduced in version 0.27.

get_menu_items_hidden

Signature: map<string,bool> **get_menu_items_hidden**

Description: Gets the flags indicating whether menu items are hidden

This method returns a hash with the hidden flag vs. menu item path. You can use this hash with set_menu_items_hidden.

This method has been introduced in version 0.27.

grid_micron

Signature: *[const]* double **grid_micron**

Description: Gets the global grid in micron

Returns: The global grid in micron

The global grid is used at various places, i.e. for ruler snapping, for grid display etc.

index_of

Signature: *[const]* int **index_of** (const LayoutView ptr view)

Description: Gets the index of the given view

Returns: The index of the view that was given

If the given view is not a view object within the main window, a negative value will be returned.

This method has been added in version 0.25.

initial_technology

Signature: string **initial_technology**

Description: Gets the technology used for creating or loading layouts (unless explicitly specified)

Returns: The current initial technology

This method was added in version 0.22.

Python specific notes:
The object exposes a readable attribute 'initial_technology'. This is the getter.

initial_technology=

Signature: void **initial_technology=** (string tech)

Description: Sets the technology used for creating or loading layouts (unless explicitly specified)

tech: The new initial technology

Setting the technology will have an effect on the next load_layout or create_layout operation which does not explicitly specify the technology but might not be reflected correctly in the reader options dialog and changes will be reset when the application is restarted.

This method was added in version 0.22.

Python specific notes:

The object exposes a writable attribute 'initial_technology'. This is the setter.

instance

Signature: *[static]* MainWindow ptr **instance**

Description: Gets application's main window instance

This method has been added in version 0.24.

load_layout

(1) Signature: CellView **load_layout** (string filename, int mode = 1)

Description: Loads a new layout

filename:	The name of the file to load
mode:	An integer value of 0, 1 or 2 that determines how the file is loaded
Returns:	The cellview into which the layout was loaded

Loads the given file into the current view, replacing the current layouts (mode 0), into a new view (mode 1) or adding the layout to the current view (mode 2). In mode 1, the new view is made the current one.

This version will use the initial technology and the default reader options. Others versions are provided which allow specification of technology and reader options explicitly.

Starting with version 0.25, this method returns a cellview object that can be modified to configure the cellview. The 'mode' argument has been made optional in version 0.28.

(2) Signature: CellView **load_layout** (string filename, string tech, int mode = 1)

Description: Loads a new layout and associate it with the given technology

filename:	The name of the file to load
tech:	The name of the technology to use for that layout.
mode:	An integer value of 0, 1 or 2 that determines how the file is loaded
Returns:	The cellview into which the layout was loaded

Loads the given file into the current view, replacing the current layouts (mode 0), into a new view (mode 1) or adding the layout to the current view (mode 2). In mode 1, the new view is made the current one.

If the technology name is not a valid technology name, the default technology will be used. The 'mode' argument has been made optional in version 0.28.

This version was introduced in version 0.22. Starting with version 0.25, this method returns a cellview object that can be modified to configure the cellview.

(3) Signature: CellView **load_layout** (string filename, const LoadLayoutOptions options, int mode = 1)

Description: Loads a new layout with the given options

filename:	The name of the file to load
options:	The reader options to use.
mode:	An integer value of 0, 1 or 2 that determines how the file is loaded
Returns:	The cellview into which the layout was loaded

Loads the given file into the current view, replacing the current layouts (mode 0), into a new view (mode 1) or adding the layout to the current view (mode 2). In mode 1, the new view is made the current one.

This version was introduced in version 0.22. Starting with version 0.25, this method returns a cellview object that can be modified to configure the cellview. The 'mode' argument has been made optional in version 0.28.

(4) Signature: CellView **load_layout** (string filename, const LoadLayoutOptions options, string tech, int mode = 1)

Description: Loads a new layout with the given options and associate it with the given technology

filename:	The name of the file to load
options:	The reader options to use.
tech:	The name of the technology to use for that layout.
mode:	An integer value of 0, 1 or 2 that determines how the file is loaded
Returns:	The cellview into which the layout was loaded

Loads the given file into the current view, replacing the current layouts (mode 0), into a new view (mode 1) or adding the layout to the current view (mode 2). In mode 1, the new view is made the current one.

If the technology name is not a valid technology name, the default technology will be used.

This version was introduced in version 0.22. Starting with version 0.25, this method returns a cellview object that can be modified to configure the cellview. The 'mode' argument has been made optional in version 0.28.

manager

Signature: Manager **manager**

Description: Gets the Manager object of this window

The manager object is responsible to managing the undo/redo stack. Usually this object is not required. It's more convenient and safer to use the related methods provided by LayoutView (LayoutView#transaction, LayoutView#commit) and MainWindow (such as MainWindow#cm_undo and MainWindow#cm_redo).

This method has been added in version 0.24.

menu

Signature: AbstractMenu ptr **menu**

Description: Returns a reference to the abstract menu

Returns:	A reference to an AbstractMenu object representing the menu system

menu_symbols

Signature: *[static]* string[] **menu_symbols**

Description: Gets all available menu symbols (see call_menu).

NOTE: currently this method delivers a superset of all available symbols. Depending on the context, no all symbols may trigger actual functionality.

This method has been introduced in version 0.27.

message

Signature: void **message** (string message, int time = infinite)

Description: Displays a message in the status bar

message:	The message to display
time:	The time how long to display the message in ms. A negative value means 'infinitely'.

This given message is shown in the status bar for the given time.

This method has been added in version 0.18. The 'time' parameter was made optional in version 0.28.10.

on_current_view_changed

Signature: *[signal]* void **on_current_view_changed**

Description: An event indicating that the current view has changed

This event is triggered after the current view has changed. This happens, if the user switches the layout tab.

Before version 0.25 this event was based on the observer pattern obsolete now. The corresponding methods (add_current_view_observer/remove_current_view_observer) have been removed in 0.25.

Python specific notes:
The object exposes a readable attribute 'on_current_view_changed'. This is the getter.
The object exposes a writable attribute 'on_current_view_changed'. This is the setter.

on_session_about_to_be_restored

Signature: *[signal]* void **on_session_about_to_be_restored**

Description: An event indicating that a session is about to be restored

This event has been added in version 0.28.8.

Python specific notes:
The object exposes a readable attribute 'on_session_about_to_be_restored'. This is the getter.
The object exposes a writable attribute 'on_session_about_to_be_restored'. This is the setter.

on_session_restored

Signature: *[signal]* void **on_session_restored**

Description: An event indicating that a session was restored

This event has been added in version 0.28.8.

Python specific notes:
The object exposes a readable attribute 'on_session_restored'. This is the getter.
The object exposes a writable attribute 'on_session_restored'. This is the setter.

on_view_closed

Signature: *[signal]* void **on_view_closed** (int index)

Description: An event indicating that a view was closed

index: The index of the view that was closed

This event is triggered after a view was closed. For example, because the tab was closed.

This event has been added in version 0.25.

Python specific notes:
The object exposes a readable attribute 'on_view_closed'. This is the getter.
The object exposes a writable attribute 'on_view_closed'. This is the setter.

on_view_created

Signature: *[signal]* void **on_view_created** (int index)

Description: An event indicating that a new view was created

index: The index of the view that was created

This event is triggered after a new view was created. For example, if a layout is loaded into a new panel.

Before version 0.25 this event was based on the observer pattern obsolete now. The corresponding methods (add_new_view_observer/remove_new_view_observer) have been removed in 0.25.

Python specific notes:
The object exposes a readable attribute 'on_view_created'. This is the getter.

The object exposes a writable attribute 'on_view_created'. This is the setter.

read_config

Signature: bool **read_config** (string file_name)

Description: Reads the configuration from a file

This method is provided for using MainWindow without an Application object. It's a convience method which is equivalent to 'dispatcher().read_config(...)'. See Dispatcher#read_config for details.

This method has been introduced in version 0.27.

redraw

Signature: void **redraw**

Description: Redraws the current view

Issues a redraw request to the current view. This usually happens automatically, so this method does not need to be called in most relevant cases.

resize

Signature: void **resize** (int width, int height)

Description: Resizes the window

width: The new width of the window

height: The new width of the window

This method resizes the window to the given target size including decoration such as menu bar and control panels

restore_session

Signature: void **restore_session** (string fn)

Description: Restores a session from the given file

fn: The path to the session file

The session stored in the given session file is restored. All existing views are closed and all layout edits are discarded without notification.

This method was added in version 0.18.

save_session

Signature: void **save_session** (string fn)

Description: Saves the session to the given file

fn: The path to the session file

The session is saved to the given session file. Any existing layout edits are not automatically saved together with the session. The session just holds display settings and annotation objects. If layout edits exist, they have to be saved explicitly in a separate step.

This method was added in version 0.18.

select_view

Signature: void **select_view** (int index)

Description: Selects the view with the given index

index: The index of the view to select (0 is the first)

Use of this method is deprecated. Use current_view_index= instead

This method will make the view with the given index the current (front) view.

This method was renamed from select_view to current_view_index= in version 0.25. The old name is still available, but deprecated.

Python specific notes:

The object exposes a writable attribute 'current_view_index'. This is the setter.

set_config

Signature: void **set_config** (string name, string value)

Description: Set a local configuration parameter with the given name to the given value

This method is provided for using MainWindow without an Application object. It's a convience method which is equivalent to 'dispatcher().set_config(...)'. See Dispatcher#set_config for details.

This method has been introduced in version 0.27.

set_key_bindings

Signature: void **set_key_bindings** (map<string,string> bindings)

Description: Sets key bindings.

Sets the given key bindings. Pass a hash listing the key bindings per menu item paths. Key strings follow the usual notation, e.g. 'Ctrl+A', 'Shift+X' or just 'F2'. Use an empty value to remove a key binding from a menu entry.

get_key_bindings will give you the current key bindings, get_default_key_bindings will give you the default ones.

Examples:

```
# reset all key bindings to default:
mw = RBA::MainWindow.instance()
mw.set_key_bindings(mw.get_default_key_bindings())

# disable key binding for 'copy':
RBA::MainWindow.instance.set_key_bindings({ "edit_menu.copy" => "" })

# configure 'copy' to use Shift+K and 'cut' to use Ctrl+K:
RBA::MainWindow.instance.set_key_bindings({ "edit_menu.copy" => "Shift+K",
 "edit_menu.cut" => "Ctrl+K" })
```

This method has been introduced in version 0.27.

set_menu_items_hidden

Signature: void **set_menu_items_hidden** (map<string,bool> flags)

Description: sets the flags indicating whether menu items are hidden

This method allows hiding certain menu items. It takes a hash with hidden flags vs. menu item paths. Examples:

```
# show all menu items:
mw = RBA::MainWindow.instance()
mw.set_menu_items_hidden(mw.get_default_menu_items_hidden())

# hide the 'copy' entry from the 'Edit' menu:
RBA::MainWindow.instance().set_menu_items_hidden({ "edit_menu.copy" =>
 true })
```

This method has been introduced in version 0.27.

show_macro_editor

Signature: void **show_macro_editor** (string cat = , bool add = false)

Description: Shows the macro editor

If 'cat' is given, this category will be selected in the category tab. If 'add' is true, the 'new macro' dialog will be opened.

This method has been introduced in version 0.26.

synchronous

(1) Signature: void **synchronous** (bool sync_mode)

Description: Puts the main window into synchronous mode

sync_mode: 'true' if the application should behave synchronously

Use of this method is deprecated. Use synchronous= instead

In synchronous mode, an application is allowed to block on redraw. While redrawing, no user interactions are possible. Although this is not desirable for smooth operation, it can be beneficial for test or automation purposes, i.e. if a screenshot needs to be produced once the application has finished drawing.

Python specific notes:
The object exposes a writable attribute 'synchronous'. This is the setter.
This method is available as 'synchronous_' in Python to distiguish it from the property with the same name.

(2) Signature: *[const]* bool **synchronous**

Description: Gets a value indicating whether synchronous mode is activated

See synchronous= for details about this attribute

This property getter was introduced in version 0.29.

Python specific notes:
The object exposes a readable attribute 'synchronous'. This is the getter.

synchronous=

Signature: void **synchronous=** (bool sync_mode)

Description: Puts the main window into synchronous mode

sync_mode: 'true' if the application should behave synchronously

In synchronous mode, an application is allowed to block on redraw. While redrawing, no user interactions are possible. Although this is not desirable for smooth operation, it can be beneficial for test or automation purposes, i.e. if a screenshot needs to be produced once the application has finished drawing.

Python specific notes:
The object exposes a writable attribute 'synchronous'. This is the setter.
This method is available as 'synchronous_' in Python to distiguish it from the property with the same name.

title

Signature: *[const]* string **title**

Description: Gets the window title

See title= for a description of this property. This property was introduced in version 0.29.

Python specific notes:
The object exposes a readable attribute 'title'. This is the getter.

title=

Signature: void **title=** (string title)

Description: Sets the window title

If the window title is not empty, it will be used for the application window's title. Otherwise the default title is used. The title string is subject to expression interpolation. So it is possible to implement the default scheme of adding the current view using the following code:

```
add_view_info = "$(var view=LayoutView.current; view ? ' - ' +
 (view.is_dirty ? '[+] ' : '') + view.title : '')"
```

```
RBA::MainWindow.instance.title = "Custom Title" + add_view_info
```

This property was introduced in version 0.29.

Python specific notes:
The object exposes a writable attribute 'title'. This is the setter.

view

Signature: LayoutView ptr **view** (int n)

Description: Returns a reference to a view object by index

Returns: The view object's reference for the view with the given index.

views

Signature: *[const]* unsigned int **views**

Description: Returns the number of views

Returns: The number of views available so far.

write_config

Signature: bool **write_config** (string file_name)

Description: Writes configuration to a file

This method is provided for using MainWindow without an Application object. It's a convience method which is equivalent to 'dispatcher().write_config(...)'. See Dispatcher#write_config for details.

This method has been introduced in version 0.27.

4.233. API reference - Class Application

Notation used in Ruby API documentation

Module: lay

Description: The application object

Class hierarchy: Application » QCoreApplication » QObject

The application object is the main port from which to access all the internals of the application, in particular the main window.

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**add_macro_category**	(string name, string description, string[] folders)	Creates a new macro category
[const]	string	**application_data_path**		Returns the application's data path (where the configuration file is stored for example)
	string	**arch**		Returns the architecture string
	void	**commit_config**		Commits the configuration settings
	int	**execute**		Executes the application's main loop
	void	**exit**	(int result)	Ends the application with the given exit status
[const]	string	**get_config**	(string name)	Gets the value for a configuration parameter
[const]	string[]	**get_config_names**		Gets the configuration parameter names
[const]	string	**inst_path**		Returns the application's installation path (where the executable is located)
[const]	bool	**is_editable?**		Returns true if the application is in editable mode
[const]	string[]	**klayout_path**		Returns the KLayout path (search path for KLayout components)

[const]	MainWindow ptr	**main_window**		Returns a reference to the main window
[signal]	void	**on_salt_changed**		This event is triggered when the package status changes.
	void	**process_events**		Processes pending events
	bool	**read_config**	(string file_name)	Reads the configuration from a file
	void	**set_config**	(string name, string value)	Sets a configuration parameter with the given name to the given value
	string	**version**		Returns the application's version string
	bool	**write_config**	(string file_name)	Writes configuration to a file

Public static methods and constants

Application ptr	**instance**	Return the singleton instance of the application

Deprecated methods (protected, public, static, non-static and constructors)

int	**exec**	Use of this method is deprecated. Use execute instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

add_macro_category

Signature: void **add_macro_category** (string name, string description, string[] folders)

Description: Creates a new macro category

Creating a new macro category is only possible during the autorun_early stage. The new macro category must correspond to an interpreter registered at the same stage. This method has been introduced in version 0.28.

application_data_path

Signature: *[const]* string **application_data_path**

Description: Returns the application's data path (where the configuration file is stored for example)

This method has been added in version 0.22.

arch

Signature: string **arch**

Description: Returns the architecture string

This method has been introduced in version 0.25.

commit_config

Signature: void **commit_config**

Description: Commits the configuration settings

Some configuration options are queued for performance reasons and become active only after 'commit_config' has been called. After a sequence of set_config calls, this method should be called to activate the settings made by these calls.

This method has been introduced in version 0.25.

exec

Signature: int **exec**

Description: Executes the application's main loop

Use of this method is deprecated. Use execute instead

This method must be called in order to execute the application in the main script if a script is provided.

Python specific notes:
This attribute is available as 'exec_' in Python.

execute

Signature: int **execute**

Description: Executes the application's main loop

This method must be called in order to execute the application in the main script if a script is provided.

Python specific notes:
This attribute is available as 'exec_' in Python.

exit

Signature: void **exit** (int result)

Description: Ends the application with the given exit status

This method should be called instead of simply shutting down the process. It performs some important cleanup without which the process might crash. If the result code is 0 (success), the configuration file will be updated unless that has been disabled by the -nc command line switch. This method has been added in version 0.22.

get_config

Signature: *[const]* string **get_config** (string name)

Description: Gets the value for a configuration parameter

name:	The name of the configuration parameter whose value shall be obtained (a string)
Returns:	The value of the parameter

This method returns the value of the given configuration parameter. If the parameter is not known, an exception will be thrown. Use get_config_names to obtain a list of all configuration parameter names available.

Configuration parameters are always stored as strings. The actual format of this string is specific to the configuration parameter. The values delivered by this method correspond to the values stored in the configuration file

get_config_names

Signature: *[const]* string[] **get_config_names**

Description: Gets the configuration parameter names

Returns:	A list of configuration parameter names

This method returns the names of all known configuration parameters. These names can be used to get and set configuration parameter values.

inst_path

Signature: *[const]* string **inst_path**

Description: Returns the application's installation path (where the executable is located)

This method has been added in version 0.18. Version 0.22 offers the method klayout_path which delivers all components of the search path.

instance

Signature: *[static]* Application ptr **instance**

Description: Return the singleton instance of the application

There is exactly one instance of the application. This instance can be obtained with this method.

is_editable?

Signature: *[const]* bool **is_editable?**

Description: Returns true if the application is in editable mode

klayout_path

Signature: *[const]* string[] **klayout_path**

Description: Returns the KLayout path (search path for KLayout components)

The result is an array containing the components of the path.

This method has been added in version 0.22.

main_window

Signature: *[const]* MainWindow ptr **main_window**

Description: Returns a reference to the main window

Returns: A object reference to the main window object.

on_salt_changed

Signature: *[signal]* void **on_salt_changed**

Description: This event is triggered when the package status changes.

Register to this event if you are interested in package changes - i.e. installation or removal of packages or package updates.

This event has been introduced in version 0.28.

Python specific notes:
The object exposes a readable attribute 'on_salt_changed'. This is the getter.
The object exposes a writable attribute 'on_salt_changed'. This is the setter.

process_events

Signature: void **process_events**

Description: Processes pending events

This method processes pending events and dispatches them internally. Calling this method periodically during a long operation keeps the application 'alive'

read_config

Signature: bool **read_config** (string file_name)

Description: Reads the configuration from a file

Returns: A value indicating whether the operation was successful

This method silently does nothing, if the config file does not exist. If it does and an error occurred, the error message is printed on stderr. In both cases, false is returned.

set_config

Signature: void **set_config** (string name, string value)

Description: Sets a configuration parameter with the given name to the given value

name: The name of the configuration parameter to set

value: The value to which to set the configuration parameter

This method sets the configuration parameter with the given name to the given value. Values can only be strings. Numerical values have to be converted into strings first. The actual format of the value depends on the configuration parameter. The name must be one of the names returned by get_config_names. It is possible to write an arbitrary name/value pair into the configuration database which then is written to the configuration file.

version

Signature: string **version**

Description: Returns the application's version string

write_config

Signature: bool **write_config** (string file_name)

Description: Writes configuration to a file

Returns: A value indicating whether the operation was successful

If the configuration file cannot be written, is returned but no exception is thrown.

4.234. API reference - Class LEFDEFReaderConfiguration

Notation used in Ruby API documentation

Module: db

Description: Detailed LEF/DEF reader options

This class is a aggregate belonging to the LoadLayoutOptions class. It provides options for the LEF/DEF reader. These options have been placed into a separate class to account for their complexity. This class specifically handles layer mapping. This is the process of generating layer names or GDS layer/datatypes from LEF/DEF layers and purpose combinations. There are basically two ways: to use a map file or to use pattern-based production rules.

To use a layer map file, set the map_file attribute to the name of the layer map file. The layer map file lists the GDS layer and datatype numbers to generate for the geometry.

The pattern-based approach will use the layer name and attach a purpose-dependent suffix to it. Use the ..._suffix attributes to specify this suffix. For routing, the corresponding attribute is routing_suffix for example. A purpose can also be mapped to a specific GDS datatype using the corresponding ..._datatype attributes. The decorated or undecorated names are looked up in a layer mapping table in the next step. The layer mapping table is specified using the layer_map attribute. This table can be used to map layer names to specific GDS layers by using entries of the form 'NAME: layer-number'.

If a layer map file is present, the pattern-based attributes are ignored.

Public constructors

new LEFDEFReaderConfiguration ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const LEFDEFReaderC other)	Assigns another object to self
[const]	int	**blockages_datatype**		Gets the blockage marker layer datatype value.
	void	**blockages_datatype=**	(int datatype)	Sets the blockage marker layer datatype value.
[const]	string	**blockages_suffix**		Gets the blockage marker layer name suffix.
	void	**blockages_suffix=**	(string suffix)	Sets the blockage marker layer name suffix.

[const]	string	**cell_outline_layer**		Gets the layer on which to produce the cell outline (diearea).
	void	**cell_outline_layer=**	(string spec)	Sets the layer on which to produce the cell outline (diearea).
	void	**clear_fill_datatypes_per_mask**		Clears the fill layer datatypes per mask.
	void	**clear_fills_suffixes_per_mas**		Clears the fill layer name suffix per mask.
	void	**clear_lef_pins_datatypes_per_mask**		Clears the LEF pin layer datatypes per mask.
	void	**clear_lef_pins_suffixes_per_**		Clears the LEF pin layer name suffix per mask.
	void	**clear_pin_datatypes_per_mask**		Clears the pin layer datatypes per mask.
	void	**clear_pins_suffixes_per_ma**		Clears the pin layer name suffix per mask.
	void	**clear_routing_datatypes_per_mask**		Clears the routing layer datatypes per mask.
	void	**clear_routing_suffixes_per_**		Clears the routing layer name suffix per mask.
	void	**clear_special_routing_datatypes_per_mask**		Clears the special routing layer datatypes per mask.
	void	**clear_special_routing_suffix**		Clears the special routing layer name suffix per mask.
	void	**clear_via_geometry_datatypes_per_mask**		Clears the via geometry layer datatypes per mask.
	void	**clear_via_geometry_suffixes**		Clears the via geometry layer name suffix per mask.
[const]	bool	**create_other_layers**		Gets a value indicating whether layers not mapped in the layer map shall be created too
	void	**create_other_layers=**	(bool f)	Sets a value indicating whether layers not mapped in the layer map shall be created too
[const]	double	**dbu**		Gets the database unit to use for producing the layout.
	void	**dbu=**	(double dbu)	Sets the database unit to use for producing the layout.
[const]	new LEFDEFReaderConfiguration ptr	**dup**		Creates a copy of self
[const]	int	**fills_datatype**		Gets the fill geometry layer datatype value.
[const]	int	**fills_datatype**	(unsigned int mask)	Gets the fill geometry layer datatype value per mask.
	void	**fills_datatype=**	(int datatype)	Sets the fill geometry layer datatype value.
[const]	string	**fills_suffix**		Gets the fill geometry layer name suffix.

	void	fills_suffix=	(string suffix)	Sets the fill geometry layer name suffix.
[const]	string	fills_suffix_per_mask	(unsigned int mask)	Gets the fill geometry layer name suffix per mask.
[const]	variant	instance_property_name		Gets a value indicating whether and how to produce instance names as properties.
	void	instance_property_name=	(variant name)	Sets a value indicating whether and how to produce instance names as properties.
[const]	bool	joined_paths		Gets a value indicating whether to create joined paths for wires.
	void	joined_paths=	(bool flag)	Sets a value indicating whether to create joined paths for wires.
[const]	int	labels_datatype		Gets the labels layer datatype value.
	void	labels_datatype=	(int datatype)	Sets the labels layer datatype value.
[const]	string	labels_suffix		Gets the label layer name suffix.
	void	labels_suffix=	(string suffix)	Sets the label layer name suffix.
	LayerMap	layer_map		Gets the layer map to be used for the LEF/DEF reader
	void	layer_map=	(const LayerMap m)	Sets the layer map to be used for the LEF/DEF reader
[const]	string[]	lef_files		Gets the list technology LEF files to additionally import
	void	lef_files=	(string[] lef_file_paths)	Sets the list technology LEF files to additionally import
[const]	int	lef_labels_datatype		Gets the lef_labels layer datatype value.
	void	lef_labels_datatype=	(int datatype)	Sets the lef_labels layer datatype value.
[const]	string	lef_labels_suffix		Gets the label layer name suffix.
	void	lef_labels_suffix=	(string suffix)	Sets the label layer name suffix.
[const]	int	lef_pins_datatype		Gets the LEF pin geometry layer datatype value.
[const]	int	lef_pins_datatype	(unsigned int mask)	Gets the LEF pin geometry layer datatype value per mask.
	void	lef_pins_datatype=	(int datatype)	Sets the LEF pin geometry layer datatype value.
[const]	string	lef_pins_suffix		Gets the LEF pin geometry layer name suffix.
	void	lef_pins_suffix=	(string suffix)	Sets the LEF pin geometry layer name suffix.

[const]	string	**lef_pins_suffix_per_mask**	(unsigned int mask)	Gets the LEF pin geometry layer name suffix per mask.
[const]	string[]	**macro_layout_files**		Gets the list of layout files to read for substituting macros in DEF
	void	**macro_layout_files=**	(string[] file_paths)	Sets the list of layout files to read for substituting macros in DEF
[const]	Layout ptr[]	**macro_layouts**		Gets the layout objects used for resolving LEF macros in the DEF reader.
	void	**macro_layouts=**	(Layout ptr[] layouts)	Sets the layout objects used for resolving LEF macros in the DEF reader.
[const]	unsigned int	**macro_resolution_mode**		Gets the macro resolution mode (LEF macros into DEF).
	void	**macro_resolution_mode=**	(unsigned int mode)	Sets the macro resolution mode (LEF macros into DEF).
[const]	string	**map_file**		Gets the layer map file to use.
	void	**map_file=**	(string file)	Sets the layer map file to use.
[const]	variant	**net_property_name**		Gets a value indicating whether and how to produce net names as properties.
	void	**net_property_name=**	(variant name)	Sets a value indicating whether and how to produce net names as properties.
[const]	int	**obstructions_datatype**		Gets the obstruction marker layer datatype value.
	void	**obstructions_datatype=**	(int datatype)	Sets the obstruction marker layer datatype value.
[const]	string	**obstructions_suffix**		Gets the obstruction marker layer name suffix.
	void	**obstructions_suffix=**	(string suffix)	Sets the obstruction marker layer name suffix.
	void	**paths_relative_to_cwd=**	(bool f)	Sets a value indicating whether to use paths relative to cwd (true) or DEF file (false) for map or LEF files
[const]	variant	**pin_property_name**		Gets a value indicating whether and how to produce pin names as properties.
	void	**pin_property_name=**	(variant name)	Sets a value indicating whether and how to produce pin names as properties.
[const]	int	**pins_datatype**		Gets the pin geometry layer datatype value.
[const]	int	**pins_datatype**	(unsigned int mask)	Gets the pin geometry layer datatype value per mask.
	void	**pins_datatype=**	(int datatype)	Sets the pin geometry layer datatype value.

[const]	string	**pins_suffix**		Gets the pin geometry layer name suffix.
	void	**pins_suffix=**	(string suffix)	Sets the pin geometry layer name suffix.
[const]	string	**pins_suffix_per_mask**	(unsigned int mask)	Gets the pin geometry layer name suffix per mask.
[const]	string	**placement_blockage_layer**		Gets the layer on which to produce the placement blockage.
	void	**placement_blockage_layer=**	(string layer)	Sets the layer on which to produce the placement blockage.
[const]	bool	**produce_blockages**		Gets a value indicating whether routing blockage markers shall be produced.
	void	**produce_blockages=**	(bool produce)	Sets a value indicating whether routing blockage markers shall be produced.
[const]	bool	**produce_cell_outlines**		Gets a value indicating whether to produce cell outlines (diearea).
	void	**produce_cell_outlines=**	(bool produce)	Sets a value indicating whether to produce cell outlines (diearea).
[const]	bool	**produce_fills**		Gets a value indicating whether fill geometries shall be produced.
	void	**produce_fills=**	(bool produce)	Sets a value indicating whether fill geometries shall be produced.
[const]	bool	**produce_labels**		Gets a value indicating whether labels shall be produced.
	void	**produce_labels=**	(bool produce)	Sets a value indicating whether labels shall be produced.
[const]	bool	**produce_lef_labels**		Gets a value indicating whether lef_labels shall be produced.
	void	**produce_lef_labels=**	(bool produce)	Sets a value indicating whether lef_labels shall be produced.
[const]	bool	**produce_lef_pins**		Gets a value indicating whether LEF pin geometries shall be produced.
	void	**produce_lef_pins=**	(bool produce)	Sets a value indicating whether LEF pin geometries shall be produced.
[const]	bool	**produce_obstructions**		Gets a value indicating whether obstruction markers shall be produced.
	void	**produce_obstructions=**	(bool produce)	Sets a value indicating whether obstruction markers shall be produced.
[const]	bool	**produce_pins**		Gets a value indicating whether pin geometries shall be produced.

	void	produce_pins=	(bool produce)	Sets a value indicating whether pin geometries shall be produced.
[const]	bool	produce_placement_blockages		Gets a value indicating whether to produce placement blockage regions.
	void	produce_placement_blockag	(bool produce)	Sets a value indicating whether to produce placement blockage regions.
[const]	bool	produce_regions		Gets a value indicating whether to produce regions.
	void	produce_regions=	(bool produce)	Sets a value indicating whether to produce regions.
[const]	bool	produce_routing		Gets a value indicating whether routing geometry shall be produced.
	void	produce_routing=	(bool produce)	Sets a value indicating whether routing geometry shall be produced.
[const]	bool	produce_special_routing		Gets a value indicating whether special routing geometry shall be produced.
	void	produce_special_routing=	(bool produce)	Sets a value indicating whether special routing geometry shall be produced.
[const]	bool	produce_via_geometry		Sets a value indicating whether via geometries shall be produced.
	void	produce_via_geometry=	(bool produce)	Sets a value indicating whether via geometries shall be produced.
[const]	bool	read_lef_with_def		Gets a value indicating whether to read all LEF files in the same directory than the DEF file.
	void	read_lef_with_def=	(bool flag)	Sets a value indicating whether to read all LEF files in the same directory than the DEF file.
[const]	string	region_layer		Gets the layer on which to produce the regions.
	void	region_layer=	(string layer)	Sets the layer on which to produce the regions.
[const]	int	routing_datatype		Gets the routing layer datatype value.
[const]	int	routing_datatype	(unsigned int mask)	Gets the routing geometry layer datatype value per mask.
	void	routing_datatype=	(int datatype)	Sets the routing layer datatype value.
[const]	string	routing_suffix		Gets the routing layer name suffix.
	void	routing_suffix=	(string suffix)	Sets the routing layer name suffix.
[const]	string	routing_suffix_per_mask	(unsigned int mask)	Gets the routing geometry layer name suffix per mask.

[const]	bool	separate_groups		Gets a value indicating whether to create separate parent cells for individual groups.
	void	separate_groups=	(bool flag)	Sets a value indicating whether to create separate parent cells for individual groups.
	void	set_fills_datatype_per_mask	(unsigned int mask, int datatype)	Sets the fill geometry layer datatype value.
	void	set_fills_suffix_per_mask	(unsigned int mask, string suffix)	Sets the fill geometry layer name suffix per mask.
	void	set_lef_pins_datatype_per_mask	(unsigned int mask, int datatype)	Sets the LEF pin geometry layer datatype value.
	void	set_lef_pins_suffix_per_mas	(unsigned int mask, string suffix)	Sets the LEF pin geometry layer name suffix per mask.
	void	set_pins_datatype_per_mask	(unsigned int mask, int datatype)	Sets the pin geometry layer datatype value.
	void	set_pins_suffix_per_mask	(unsigned int mask, string suffix)	Sets the pin geometry layer name suffix per mask.
	void	set_routing_datatype_per_mask	(unsigned int mask, int datatype)	Sets the routing geometry layer datatype value.
	void	set_routing_suffix_per_masl	(unsigned int mask, string suffix)	Sets the routing geometry layer name suffix per mask.
	void	set_special_routing_datatype_per_mask	(unsigned int mask, int datatype)	Sets the special routing geometry layer datatype value.
	void	set_special_routing_suffix_p	(unsigned int mask, string suffix)	Sets the special routing geometry layer name suffix per mask.
	void	set_via_geometry_datatype_per_mask	(unsigned int mask, int datatype)	Sets the via geometry layer datatype value.
	void	set_via_geometry_suffix_pe	(unsigned int mask, string suffix)	Sets the via geometry layer name suffix per mask.
[const]	int	special_routing_datatype		Gets the special routing layer datatype value.
[const]	int	special_routing_datatype	(unsigned int mask)	Gets the special routing geometry layer datatype value per mask.

	void	special_routing_datatype=	(int datatype)	Sets the special routing layer datatype value.
[const]	string	special_routing_suffix		Gets the special routing layer name suffix.
	void	special_routing_suffix=	(string suffix)	Sets the special routing layer name suffix.
[const]	string	special_routing_suffix_per_m	(unsigned int mask)	Gets the special routing geometry layer name suffix per mask.
[const]	string	via_cellname_prefix		Gets the via cellname prefix.
	void	via_cellname_prefix=	(string prefix)	Sets the via cellname prefix.
[const]	int	via_geometry_datatype		Gets the via geometry layer datatype value.
[const]	int	via_geometry_datatype	(unsigned int mask)	Gets the via geometry layer datatype value per mask.
	void	via_geometry_datatype=	(int datatype)	Sets the via geometry layer datatype value.
[const]	string	via_geometry_suffix		Gets the via geometry layer name suffix.
	void	via_geometry_suffix=	(string suffix)	Sets the via geometry layer name suffix.
[const]	string	via_geometry_suffix_per_ma	(unsigned int mask)	Gets the via geometry layer name suffix per mask.

Deprecated methods (protected, public, static, non-static and constructors)

	void	create	Use of this method is deprecated. Use _create instead
	void	destroy	Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	is_const_object?	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const LEFDEFReaderConfiguration other)

Description: Assigns another object to self

blockages_datatype

Signature: *[const]* int **blockages_datatype**

Description: Gets the blockage marker layer datatype value.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a readable attribute 'blockages_datatype'. This is the getter.

blockages_datatype=

Signature: void **blockages_datatype=** (int datatype)

Description: Sets the blockage marker layer datatype value.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a writable attribute 'blockages_datatype'. This is the setter.

blockages_suffix

Signature: *[const]* string **blockages_suffix**

Description: Gets the blockage marker layer name suffix.

See produce_via_geometry for details about the layer production rules.

Python specific notes:

	The object exposes a readable attribute 'blockages_suffix'. This is the getter.
blockages_suffix=	**Signature**: void **blockages_suffix=** (string suffix) **Description**: Sets the blockage marker layer name suffix. See produce_via_geometry for details about the layer production rules. **Python specific notes:** The object exposes a writable attribute 'blockages_suffix'. This is the setter.
cell_outline_layer	**Signature**: *[const]* string **cell_outline_layer** **Description**: Gets the layer on which to produce the cell outline (diearea). This attribute is a string corresponding to the string representation of LayerInfo. This string can be either a layer number, a layer/datatype pair, a name or a combination of both. See LayerInfo for details. The setter for this attribute is cell_outline_layer=. See also produce_cell_outlines. **Python specific notes:** The object exposes a readable attribute 'cell_outline_layer'. This is the getter.
cell_outline_layer=	**Signature**: void **cell_outline_layer=** (string spec) **Description**: Sets the layer on which to produce the cell outline (diearea). See cell_outline_layer for details. **Python specific notes:** The object exposes a writable attribute 'cell_outline_layer'. This is the setter.
clear_fill_datatypes_per_mask	**Signature**: void **clear_fill_datatypes_per_mask** **Description**: Clears the fill layer datatypes per mask. See produce_via_geometry for details about this property. Mask specific rules have been introduced in version 0.27.
clear_fills_suffixes_per_mask	**Signature**: void **clear_fills_suffixes_per_mask** **Description**: Clears the fill layer name suffix per mask. See produce_via_geometry for details about this property. Mask specific rules have been introduced in version 0.27.
clear_lef_pins_datatypes_per_mask	**Signature**: void **clear_lef_pins_datatypes_per_mask** **Description**: Clears the LEF pin layer datatypes per mask. See produce_via_geometry for details about this property. Mask specific rules have been introduced in version 0.27.
clear_lef_pins_suffixes_per_ma	**Signature**: void **clear_lef_pins_suffixes_per_mask** **Description**: Clears the LEF pin layer name suffix per mask. See produce_via_geometry for details about this property. Mask specific rules have been introduced in version 0.27.
clear_pin_datatypes_per_mask	**Signature**: void **clear_pin_datatypes_per_mask** **Description**: Clears the pin layer datatypes per mask. See produce_via_geometry for details about this property.

	Mask specific rules have been introduced in version 0.27.
clear_pins_suffixes_per_mask	**Signature**: void **clear_pins_suffixes_per_mask** **Description**: Clears the pin layer name suffix per mask. See produce_via_geometry for details about this property. Mask specific rules have been introduced in version 0.27.
clear_routing_datatypes_per_mask	**Signature**: void **clear_routing_datatypes_per_mask** **Description**: Clears the routing layer datatypes per mask. See produce_via_geometry for details about this property. Mask specific rules have been introduced in version 0.27.
clear_routing_suffixes_per_ma	**Signature**: void **clear_routing_suffixes_per_mask** **Description**: Clears the routing layer name suffix per mask. See produce_via_geometry for details about this property. Mask specific rules have been introduced in version 0.27.
clear_special_routing_datatypes_per_mask	**Signature**: void **clear_special_routing_datatypes_per_mask** **Description**: Clears the special routing layer datatypes per mask. See produce_via_geometry for details about this property. Mask specific rules have been introduced in version 0.27.
clear_special_routing_suffixes_	**Signature**: void **clear_special_routing_suffixes_per_mask** **Description**: Clears the special routing layer name suffix per mask. See produce_via_geometry for details about this property. Mask specific rules have been introduced in version 0.27.
clear_via_geometry_datatypes_per_mask	**Signature**: void **clear_via_geometry_datatypes_per_mask** **Description**: Clears the via geometry layer datatypes per mask. See produce_via_geometry for details about this property. Mask specific rules have been introduced in version 0.27.
clear_via_geometry_suffixes_p	**Signature**: void **clear_via_geometry_suffixes_per_mask** **Description**: Clears the via geometry layer name suffix per mask. See produce_via_geometry for details about this property. Mask specific rules have been introduced in version 0.27.
create	**Signature**: void **create** **Description**: Ensures the C++ object is created Use of this method is deprecated. Use _create instead Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

create_other_layers

Signature: *[const]* bool **create_other_layers**

Description: Gets a value indicating whether layers not mapped in the layer map shall be created too

See layer_map for details.

Python specific notes:
The object exposes a readable attribute 'create_other_layers'. This is the getter.

create_other_layers=

Signature: void **create_other_layers=** (bool f)

Description: Sets a value indicating whether layers not mapped in the layer map shall be created too

See layer_map for details.

Python specific notes:
The object exposes a writable attribute 'create_other_layers'. This is the setter.

dbu

Signature: *[const]* double **dbu**

Description: Gets the database unit to use for producing the layout.

This value specifies the database to be used for the layout that is read. When a DEF file is specified with a different database unit, the layout is translated into this database unit.

Python specific notes:
The object exposes a readable attribute 'dbu'. This is the getter.

dbu=

Signature: void **dbu=** (double dbu)

Description: Sets the database unit to use for producing the layout.

See dbu for details.

Python specific notes:
The object exposes a writable attribute 'dbu'. This is the setter.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new LEFDEFReaderConfiguration ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

fills_datatype

(1) Signature: *[const]* int **fills_datatype**

Description: Gets the fill geometry layer datatype value.

See produce_via_geometry for details about the layer production rules.

Fill support has been introduced in version 0.27.

Python specific notes:
The object exposes a readable attribute 'fills_datatype'. This is the getter.

(2) Signature: *[const]* int **fills_datatype** (unsigned int mask)

Description: Gets the fill geometry layer datatype value per mask.

See produce_via_geometry for details about the layer production rules.The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...).

Mask specific rules have been introduced in version 0.27.

Python specific notes:
This method is available as 'fills_datatype_' in Python to distiguish it from the property with the same name.

fills_datatype=

Signature: void **fills_datatype=** (int datatype)

Description: Sets the fill geometry layer datatype value.

See produce_via_geometry for details about the layer production rules.

Fill support has been introduced in version 0.27.

Python specific notes:
The object exposes a writable attribute 'fills_datatype'. This is the setter.

fills_suffix

Signature: *[const]* string **fills_suffix**

Description: Gets the fill geometry layer name suffix.

See produce_via_geometry for details about the layer production rules.

Fill support has been introduced in version 0.27.

Python specific notes:
The object exposes a readable attribute 'fills_suffix'. This is the getter.

fills_suffix=

Signature: void **fills_suffix=** (string suffix)

Description: Sets the fill geometry layer name suffix.

See produce_via_geometry for details about the layer production rules.

Fill support has been introduced in version 0.27.

Python specific notes:
The object exposes a writable attribute 'fills_suffix'. This is the setter.

fills_suffix_per_mask

Signature: *[const]* string **fills_suffix_per_mask** (unsigned int mask)

Description: Gets the fill geometry layer name suffix per mask.

See produce_via_geometry for details about the layer production rules.The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...).

Mask specific rules have been introduced in version 0.27.

instance_property_name

Signature: *[const]* variant **instance_property_name**

Description: Gets a value indicating whether and how to produce instance names as properties.

	If set to a value not nil, instance names will be attached to the instances generated as user properties. This attribute then specifies the user property name to be used for attaching the instance names. If set to nil, no instance names will be produced. The corresponding setter is instance_property_name=. This method has been introduced in version 0.26.4. **Python specific notes:** The object exposes a readable attribute 'instance_property_name'. This is the getter.
instance_property_name=	**Signature**: void **instance_property_name=** (variant name) **Description**: Sets a value indicating whether and how to produce instance names as properties. See instance_property_name for details. This method has been introduced in version 0.26.4. **Python specific notes:** The object exposes a writable attribute 'instance_property_name'. This is the setter.
is_const_object?	**Signature**: *[const]* bool **is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.
joined_paths	**Signature**: *[const]* bool **joined_paths** **Description**: Gets a value indicating whether to create joined paths for wires. If this property is set to true, wires are represented by multi-segment paths as far as possible (this will fail for 45 degree path segments for example). By defauls, wires are represented by multiple straight segments. This property has been added in version 0.28.8. **Python specific notes:** The object exposes a readable attribute 'joined_paths'. This is the getter.
joined_paths=	**Signature**: void **joined_paths=** (bool flag) **Description**: Sets a value indicating whether to create joined paths for wires. See joined_paths for details about this property. This property has been added in version 0.28.8. **Python specific notes:** The object exposes a writable attribute 'joined_paths'. This is the setter.
labels_datatype	**Signature**: *[const]* int **labels_datatype** **Description**: Gets the labels layer datatype value. See produce_via_geometry for details about the layer production rules. **Python specific notes:** The object exposes a readable attribute 'labels_datatype'. This is the getter.
labels_datatype=	**Signature**: void **labels_datatype=** (int datatype) **Description**: Sets the labels layer datatype value. See produce_via_geometry for details about the layer production rules. **Python specific notes:**

The object exposes a writable attribute 'labels_datatype'. This is the setter.

labels_suffix

Signature: *[const]* string **labels_suffix**

Description: Gets the label layer name suffix.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a readable attribute 'labels_suffix'. This is the getter.

labels_suffix=

Signature: void **labels_suffix=** (string suffix)

Description: Sets the label layer name suffix.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a writable attribute 'labels_suffix'. This is the setter.

layer_map

Signature: LayerMap **layer_map**

Description: Gets the layer map to be used for the LEF/DEF reader

Returns: A reference to the layer map

Because LEF/DEF layer mapping is substantially different than for normal layout files, the LEF/DEF reader employs a separate layer mapping table. The LEF/DEF specific layer mapping is stored within the LEF/DEF reader's configuration and can be accessed with this attribute. The layer mapping table of LoadLayoutOptions will be ignored for the LEF/DEF reader.

The setter is layer_map=. create_other_layers= is available to control whether layers not specified in the layer mapping table shall be created automatically.

Python specific notes:
The object exposes a readable attribute 'layer_map'. This is the getter.

layer_map=

Signature: void **layer_map=** (const LayerMap m)

Description: Sets the layer map to be used for the LEF/DEF reader

See layer_map for details.

Python specific notes:
The object exposes a writable attribute 'layer_map'. This is the setter.

lef_files

Signature: *[const]* string[] **lef_files**

Description: Gets the list technology LEF files to additionally import

Returns a list of path names for technology LEF files to read in addition to the primary file. Relative paths are resolved relative to the file to read or relative to the technology base path.

The setter for this property is lef_files=.

Python specific notes:
The object exposes a readable attribute 'lef_files'. This is the getter.

lef_files=

Signature: void **lef_files=** (string[] lef_file_paths)

Description: Sets the list technology LEF files to additionally import

See lef_files for details.

Python specific notes:
The object exposes a writable attribute 'lef_files'. This is the setter.

lef_labels_datatype

Signature: *[const]* int **lef_labels_datatype**

Description: Gets the lef_labels layer datatype value.

See produce_via_geometry for details about the layer production rules.

This method has been introduced in version 0.27.2

Python specific notes:
The object exposes a readable attribute 'lef_labels_datatype'. This is the getter.

lef_labels_datatype=

Signature: void **lef_labels_datatype=** (int datatype)

Description: Sets the lef_labels layer datatype value.

See produce_via_geometry for details about the layer production rules.

This method has been introduced in version 0.27.2

Python specific notes:
The object exposes a writable attribute 'lef_labels_datatype'. This is the setter.

lef_labels_suffix

Signature: *[const]* string **lef_labels_suffix**

Description: Gets the label layer name suffix.

See produce_via_geometry for details about the layer production rules.

This method has been introduced in version 0.27.2

Python specific notes:
The object exposes a readable attribute 'lef_labels_suffix'. This is the getter.

lef_labels_suffix=

Signature: void **lef_labels_suffix=** (string suffix)

Description: Sets the label layer name suffix.

See produce_via_geometry for details about the layer production rules.

This method has been introduced in version 0.27.2

Python specific notes:
The object exposes a writable attribute 'lef_labels_suffix'. This is the setter.

lef_pins_datatype

(1) Signature: *[const]* int **lef_pins_datatype**

Description: Gets the LEF pin geometry layer datatype value.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a readable attribute 'lef_pins_datatype'. This is the getter.

(2) Signature: *[const]* int **lef_pins_datatype** (unsigned int mask)

Description: Gets the LEF pin geometry layer datatype value per mask.

See produce_via_geometry for details about the layer production rules.The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...).

Mask specific rules have been introduced in version 0.27.

Python specific notes:
This method is available as 'lef_pins_datatype_' in Python to distiguish it from the property with the same name.

lef_pins_datatype=

Signature: void **lef_pins_datatype=** (int datatype)

Description: Sets the LEF pin geometry layer datatype value.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a writable attribute 'lef_pins_datatype'. This is the setter.

lef_pins_suffix

Signature: *[const]* string **lef_pins_suffix**

Description: Gets the LEF pin geometry layer name suffix.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a readable attribute 'lef_pins_suffix'. This is the getter.

lef_pins_suffix=

Signature: void **lef_pins_suffix=** (string suffix)

Description: Sets the LEF pin geometry layer name suffix.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a writable attribute 'lef_pins_suffix'. This is the setter.

lef_pins_suffix_per_mask

Signature: *[const]* string **lef_pins_suffix_per_mask** (unsigned int mask)

Description: Gets the LEF pin geometry layer name suffix per mask.

See produce_via_geometry for details about the layer production rules.The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...).

Mask specific rules have been introduced in version 0.27.

macro_layout_files

Signature: *[const]* string[] **macro_layout_files**

Description: Gets the list of layout files to read for substituting macros in DEF

These files play the same role than the macro layouts (see macro_layouts), except that this property specifies a list of file names. The given files are loaded automatically to resolve macro layouts instead of LEF geometry. See macro_resolution_mode for details when this happens. Relative paths are resolved relative to the DEF file to read or relative to the technology base path. Macros in need for substitution are looked up in the layout files by searching for cells with the same name. The files are scanned in the order they are given in the file list. The files from macro_layout_files are scanned after the layout objects specified with macro_layouts.

The setter for this property is macro_layout_files=.

This property has been added in version 0.27.1.

Python specific notes:
The object exposes a readable attribute 'macro_layout_files'. This is the getter.

macro_layout_files=

Signature: void **macro_layout_files=** (string[] file_paths)

Description: Sets the list of layout files to read for substituting macros in DEF

See macro_layout_files for details.

This property has been added in version 0.27.1.

Python specific notes:
The object exposes a writable attribute 'macro_layout_files'. This is the setter.

macro_layouts

Signature: *[const]* Layout ptr[] **macro_layouts**

Description: Gets the layout objects used for resolving LEF macros in the DEF reader.

The DEF reader can either use LEF geometry or use a separate source of layouts for the LEF macros. The macro_resolution_mode controls whether to use LEF geometry. If LEF geometry is

not used, the DEF reader will look up macro cells from the macro_layouts and pull cell layouts from there.

The LEF cells are looked up as cells by name from the macro layouts in the order these are given in this array.

macro_layout_files is another way of specifying such substitution layouts. This method accepts file names instead of layout objects.

This property has been added in version 0.27.

Python specific notes:
The object exposes a readable attribute 'macro_layouts'. This is the getter.

macro_layouts=

Signature: void **macro_layouts=** (Layout ptr[] layouts)

Description: Sets the layout objects used for resolving LEF macros in the DEF reader.

See macro_layouts for more details about this property.

Layout objects specified in the array for this property are not owned by the LEFDEFReaderConfiguration object. Be sure to keep some other reference to these Layout objects if you are storing away the LEF/DEF reader configuration object.

This property has been added in version 0.27.

Python specific notes:
The object exposes a writable attribute 'macro_layouts'. This is the setter.

macro_resolution_mode

Signature: *[const]* unsigned int **macro_resolution_mode**

Description: Gets the macro resolution mode (LEF macros into DEF).

This property describes the way LEF macros are turned into layout cells when reading DEF. There are three modes available:

- 0: produce LEF geometry unless a FOREIGN cell is specified
- 1: produce LEF geometry always and ignore FOREIGN
- 2: Never produce LEF geometry and assume FOREIGN always

If substitution layouts are specified with macro_layouts, these are used to provide macro layouts in case no LEF geometry is taken.

This property has been added in version 0.27.

Python specific notes:
The object exposes a readable attribute 'macro_resolution_mode'. This is the getter.

macro_resolution_mode=

Signature: void **macro_resolution_mode=** (unsigned int mode)

Description: Sets the macro resolution mode (LEF macros into DEF).

See macro_resolution_mode for details about this property.

This property has been added in version 0.27.

Python specific notes:
The object exposes a writable attribute 'macro_resolution_mode'. This is the setter.

map_file

Signature: *[const]* string **map_file**

Description: Gets the layer map file to use.

If a layer map file is given, the reader will pull the layer mapping from this file. The layer mapping rules specified in the reader options are ignored in this case. These are the name suffix rules for vias, blockages, routing, special routing, pins etc. and the corresponding datatype rules. The

layer_map attribute will also be ignored. The layer map file path will be resolved relative to the technology base path if the LEF/DEF reader options are used in the context of a technology.

This property has been added in version 0.27.

Python specific notes:
The object exposes a readable attribute 'map_file'. This is the getter.

map_file=

Signature: void **map_file=** (string file)

Description: Sets the layer map file to use.

See map_file for details about this property.

This property has been added in version 0.27.

Python specific notes:
The object exposes a writable attribute 'map_file'. This is the setter.

net_property_name

Signature: *[const]* variant **net_property_name**

Description: Gets a value indicating whether and how to produce net names as properties.

If set to a value not nil, net names will be attached to the net shapes generated as user properties. This attribute then specifies the user property name to be used for attaching the net names. If set to nil, no net names will be produced.

The corresponding setter is net_property_name=.

Python specific notes:
The object exposes a readable attribute 'net_property_name'. This is the getter.

net_property_name=

Signature: void **net_property_name=** (variant name)

Description: Sets a value indicating whether and how to produce net names as properties.

See net_property_name for details.

Python specific notes:
The object exposes a writable attribute 'net_property_name'. This is the setter.

new

Signature: *[static]* new LEFDEFReaderConfiguration ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

obstructions_datatype

Signature: *[const]* int **obstructions_datatype**

Description: Gets the obstruction marker layer datatype value.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a readable attribute 'obstructions_datatype'. This is the getter.

obstructions_datatype=

Signature: void **obstructions_datatype=** (int datatype)

Description: Sets the obstruction marker layer datatype value.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a writable attribute 'obstructions_datatype'. This is the setter.

obstructions_suffix

Signature: *[const]* string **obstructions_suffix**

Description: Gets the obstruction marker layer name suffix.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a readable attribute 'obstructions_suffix'. This is the getter.

obstructions_suffix=

Signature: void **obstructions_suffix=** (string suffix)

Description: Sets the obstruction marker layer name suffix.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a writable attribute 'obstructions_suffix'. This is the setter.

paths_relative_to_cwd=

Signature: void **paths_relative_to_cwd=** (bool f)

Description: Sets a value indicating whether to use paths relative to cwd (true) or DEF file (false) for map or LEF files

This write-only attribute has been introduced in version 0.27.9.

Python specific notes:
The object exposes a writable attribute 'paths_relative_to_cwd'. This is the setter.

pin_property_name

Signature: *[const]* variant **pin_property_name**

Description: Gets a value indicating whether and how to produce pin names as properties.

If set to a value not nil, pin names will be attached to the pin shapes generated as user properties. This attribute then specifies the user property name to be used for attaching the pin names. If set to nil, no pin names will be produced.

The corresponding setter is pin_property_name=.

This method has been introduced in version 0.26.4.

Python specific notes:
The object exposes a readable attribute 'pin_property_name'. This is the getter.

pin_property_name=

Signature: void **pin_property_name=** (variant name)

Description: Sets a value indicating whether and how to produce pin names as properties.

See pin_property_name for details.

This method has been introduced in version 0.26.4.

Python specific notes:
The object exposes a writable attribute 'pin_property_name'. This is the setter.

pins_datatype

(1) Signature: *[const]* int **pins_datatype**

Description: Gets the pin geometry layer datatype value.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a readable attribute 'pins_datatype'. This is the getter.

(2) Signature: *[const]* int **pins_datatype** (unsigned int mask)

Description: Gets the pin geometry layer datatype value per mask.

See produce_via_geometry for details about the layer production rules.The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...).

Mask specific rules have been introduced in version 0.27.

Python specific notes:

	This method is available as 'pins_datatype_' in Python to distiguish it from the property with the same name.
pins_datatype=	**Signature**: void **pins_datatype=** (int datatype) **Description**: Sets the pin geometry layer datatype value. See produce_via_geometry for details about the layer production rules. **Python specific notes:** The object exposes a writable attribute 'pins_datatype'. This is the setter.
pins_suffix	**Signature**: *[const]* string **pins_suffix** **Description**: Gets the pin geometry layer name suffix. See produce_via_geometry for details about the layer production rules. **Python specific notes:** The object exposes a readable attribute 'pins_suffix'. This is the getter.
pins_suffix=	**Signature**: void **pins_suffix=** (string suffix) **Description**: Sets the pin geometry layer name suffix. See produce_via_geometry for details about the layer production rules. **Python specific notes:** The object exposes a writable attribute 'pins_suffix'. This is the setter.
pins_suffix_per_mask	**Signature**: *[const]* string **pins_suffix_per_mask** (unsigned int mask) **Description**: Gets the pin geometry layer name suffix per mask. See produce_via_geometry for details about the layer production rules.The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...). Mask specific rules have been introduced in version 0.27.
placement_blockage_layer	**Signature**: *[const]* string **placement_blockage_layer** **Description**: Gets the layer on which to produce the placement blockage. This attribute is a string corresponding to the string representation of LayerInfo. This string can be either a layer number, a layer/datatype pair, a name or a combination of both. See LayerInfo for details.The setter for this attribute is placement_blockage_layer=. See also produce_placement_blockages. **Python specific notes:** The object exposes a readable attribute 'placement_blockage_layer'. This is the getter.
placement_blockage_layer=	**Signature**: void **placement_blockage_layer=** (string layer) **Description**: Sets the layer on which to produce the placement blockage. See placement_blockage_layer for details. **Python specific notes:** The object exposes a writable attribute 'placement_blockage_layer'. This is the setter.
produce_blockages	**Signature**: *[const]* bool **produce_blockages** **Description**: Gets a value indicating whether routing blockage markers shall be produced. See produce_via_geometry for details about the layer production rules. **Python specific notes:**

	The object exposes a readable attribute 'produce_blockages'. This is the getter.
produce_blockages=	**Signature**: void **produce_blockages=** (bool produce) **Description**: Sets a value indicating whether routing blockage markers shall be produced. See produce_via_geometry for details about the layer production rules. **Python specific notes:** The object exposes a writable attribute 'produce_blockages'. This is the setter.
produce_cell_outlines	**Signature**: *[const]* bool **produce_cell_outlines** **Description**: Gets a value indicating whether to produce cell outlines (diearea). If set to true, cell outlines will be produced on the layer given by cell_outline_layer. **Python specific notes:** The object exposes a readable attribute 'produce_cell_outlines'. This is the getter.
produce_cell_outlines=	**Signature**: void **produce_cell_outlines=** (bool produce) **Description**: Sets a value indicating whether to produce cell outlines (diearea). See produce_cell_outlines for details. **Python specific notes:** The object exposes a writable attribute 'produce_cell_outlines'. This is the setter.
produce_fills	**Signature**: *[const]* bool **produce_fills** **Description**: Gets a value indicating whether fill geometries shall be produced. See produce_via_geometry for details about the layer production rules. Fill support has been introduced in version 0.27. **Python specific notes:** The object exposes a readable attribute 'produce_fills'. This is the getter.
produce_fills=	**Signature**: void **produce_fills=** (bool produce) **Description**: Sets a value indicating whether fill geometries shall be produced. See produce_via_geometry for details about the layer production rules. Fill support has been introduced in version 0.27. **Python specific notes:** The object exposes a writable attribute 'produce_fills'. This is the setter.
produce_labels	**Signature**: *[const]* bool **produce_labels** **Description**: Gets a value indicating whether labels shall be produced. See produce_via_geometry for details about the layer production rules. **Python specific notes:** The object exposes a readable attribute 'produce_labels'. This is the getter.
produce_labels=	**Signature**: void **produce_labels=** (bool produce) **Description**: Sets a value indicating whether labels shall be produced. See produce_via_geometry for details about the layer production rules. **Python specific notes:** The object exposes a writable attribute 'produce_labels'. This is the setter.

produce_lef_labels

Signature: *[const]* bool **produce_lef_labels**

Description: Gets a value indicating whether lef_labels shall be produced.

See produce_via_geometry for details about the layer production rules.

This method has been introduced in version 0.27.2

Python specific notes:
The object exposes a readable attribute 'produce_lef_labels'. This is the getter.

produce_lef_labels=

Signature: void **produce_lef_labels=** (bool produce)

Description: Sets a value indicating whether lef_labels shall be produced.

See produce_via_geometry for details about the layer production rules.

This method has been introduced in version 0.27.2

Python specific notes:
The object exposes a writable attribute 'produce_lef_labels'. This is the setter.

produce_lef_pins

Signature: *[const]* bool **produce_lef_pins**

Description: Gets a value indicating whether LEF pin geometries shall be produced.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a readable attribute 'produce_lef_pins'. This is the getter.

produce_lef_pins=

Signature: void **produce_lef_pins=** (bool produce)

Description: Sets a value indicating whether LEF pin geometries shall be produced.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a writable attribute 'produce_lef_pins'. This is the setter.

produce_obstructions

Signature: *[const]* bool **produce_obstructions**

Description: Gets a value indicating whether obstruction markers shall be produced.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a readable attribute 'produce_obstructions'. This is the getter.

produce_obstructions=

Signature: void **produce_obstructions=** (bool produce)

Description: Sets a value indicating whether obstruction markers shall be produced.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a writable attribute 'produce_obstructions'. This is the setter.

produce_pins

Signature: *[const]* bool **produce_pins**

Description: Gets a value indicating whether pin geometries shall be produced.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a readable attribute 'produce_pins'. This is the getter.

produce_pins=

Signature: void **produce_pins=** (bool produce)

Description: Sets a value indicating whether pin geometries shall be produced.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a writable attribute 'produce_pins'. This is the setter.

produce_placement_blockages

Signature: *[const]* bool **produce_placement_blockages**

Description: Gets a value indicating whether to produce placement blockage regions.

If set to true, polygons will be produced representing the placement blockage region on the layer given by placement_blockage_layer.

Python specific notes:
The object exposes a readable attribute 'produce_placement_blockages'. This is the getter.

produce_placement_blockages=

Signature: void **produce_placement_blockages=** (bool produce)

Description: Sets a value indicating whether to produce placement blockage regions.

See produce_placement_blockages for details.

Python specific notes:
The object exposes a writable attribute 'produce_placement_blockages'. This is the setter.

produce_regions

Signature: *[const]* bool **produce_regions**

Description: Gets a value indicating whether to produce regions.

If set to true, polygons will be produced representing the regions on the layer given by region_layer.

The attribute has been introduced in version 0.27.

Python specific notes:
The object exposes a readable attribute 'produce_regions'. This is the getter.

produce_regions=

Signature: void **produce_regions=** (bool produce)

Description: Sets a value indicating whether to produce regions.

See produce_regions for details.

The attribute has been introduced in version 0.27.

Python specific notes:
The object exposes a writable attribute 'produce_regions'. This is the setter.

produce_routing

Signature: *[const]* bool **produce_routing**

Description: Gets a value indicating whether routing geometry shall be produced.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a readable attribute 'produce_routing'. This is the getter.

produce_routing=

Signature: void **produce_routing=** (bool produce)

Description: Sets a value indicating whether routing geometry shall be produced.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a writable attribute 'produce_routing'. This is the setter.

produce_special_routing

Signature: *[const]* bool **produce_special_routing**

Description: Gets a value indicating whether special routing geometry shall be produced.

See produce_via_geometry for details about the layer production rules.

The differentiation between special and normal routing has been introduced in version 0.27.

Python specific notes:
The object exposes a readable attribute 'produce_special_routing'. This is the getter.

produce_special_routing=

Signature: void **produce_special_routing=** (bool produce)

Description: Sets a value indicating whether special routing geometry shall be produced.

See produce_via_geometry for details about the layer production rules. The differentiation between special and normal routing has been introduced in version 0.27.

Python specific notes:
The object exposes a writable attribute 'produce_special_routing'. This is the setter.

produce_via_geometry

Signature: *[const]* bool **produce_via_geometry**

Description: Sets a value indicating whether via geometries shall be produced.

If set to true, shapes will be produced for each via. The layer to be produced will be determined from the via layer's name using the suffix provided by via_geometry_suffix. If there is a specific mapping in the layer mapping table for the via layer including the suffix, the layer/datatype will be taken from the layer mapping table. If there is a mapping to the undecorated via layer, the datatype will be substituted with the via_geometry_datatype value. If no mapping is defined, a unique number will be assigned to the layer number and the datatype will be taken from the via_geometry_datatype value.

For example: the via layer is 'V1', via_geometry_suffix is 'GEO' and via_geometry_datatype is 1. Then:

- If there is a mapping for 'V1.GEO', the layer and datatype will be taken from there.
- If there is a mapping for 'V1', the layer will be taken from there and the datatype will be taken from via_geometry_datatype. The name of the produced layer will be 'V1.GEO'.
- If there is no mapping for both, the layer number will be a unique value, the datatype will be taken from via_geometry_datatype and the layer name will be 'V1.GEO'.

Python specific notes:
The object exposes a readable attribute 'produce_via_geometry'. This is the getter.

produce_via_geometry=

Signature: void **produce_via_geometry=** (bool produce)

Description: Sets a value indicating whether via geometries shall be produced.

See produce_via_geometry for details.

Python specific notes:
The object exposes a writable attribute 'produce_via_geometry'. This is the setter.

read_lef_with_def

Signature: *[const]* bool **read_lef_with_def**

Description: Gets a value indicating whether to read all LEF files in the same directory than the DEF file.

If this property is set to true (the default), the DEF reader will automatically consume all LEF files next to the DEF file in addition to the LEF files specified with lef_files. If set to false, only the LEF files specified with lef_files will be read.

This property has been added in version 0.27.

Python specific notes:
The object exposes a readable attribute 'read_lef_with_def'. This is the getter.

read_lef_with_def=

Signature: void **read_lef_with_def=** (bool flag)

Description: Sets a value indicating whether to read all LEF files in the same directory than the DEF file.

See read_lef_with_def for details about this property.

This property has been added in version 0.27.

Python specific notes:
The object exposes a writable attribute 'read_lef_with_def'. This is the setter.

region_layer

Signature: *[const]* string **region_layer**

Description: Gets the layer on which to produce the regions.

This attribute is a string corresponding to the string representation of LayerInfo. This string can be either a layer number, a layer/datatype pair, a name or a combination of both. See LayerInfo for details.The setter for this attribute is region_layer=. See also produce_regions.

The attribute has been introduced in version 0.27.

Python specific notes:
The object exposes a readable attribute 'region_layer'. This is the getter.

region_layer=

Signature: void **region_layer=** (string layer)

Description: Sets the layer on which to produce the regions.

See region_layer for details.

The attribute has been introduced in version 0.27.

Python specific notes:
The object exposes a writable attribute 'region_layer'. This is the setter.

routing_datatype

(1) Signature: *[const]* int **routing_datatype**

Description: Gets the routing layer datatype value.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a readable attribute 'routing_datatype'. This is the getter.

(2) Signature: *[const]* int **routing_datatype** (unsigned int mask)

Description: Gets the routing geometry layer datatype value per mask.

See produce_via_geometry for details about the layer production rules.The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...).

Mask specific rules have been introduced in version 0.27.

Python specific notes:
This method is available as 'routing_datatype_' in Python to distiguish it from the property with the same name.

routing_datatype=

Signature: void **routing_datatype=** (int datatype)

Description: Sets the routing layer datatype value.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a writable attribute 'routing_datatype'. This is the setter.

routing_suffix

Signature: *[const]* string **routing_suffix**

Description: Gets the routing layer name suffix.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a readable attribute 'routing_suffix'. This is the getter.

routing_suffix=

Signature: void **routing_suffix=** (string suffix)

Description: Sets the routing layer name suffix.

See produce_via_geometry for details about the layer production rules.

Python specific notes:
The object exposes a writable attribute 'routing_suffix'. This is the setter.

routing_suffix_per_mask

Signature: *[const]* string **routing_suffix_per_mask** (unsigned int mask)

Description: Gets the routing geometry layer name suffix per mask.

See produce_via_geometry for details about the layer production rules.The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...).

Mask specific rules have been introduced in version 0.27.

separate_groups

Signature: *[const]* bool **separate_groups**

Description: Gets a value indicating whether to create separate parent cells for individual groups.

If this property is set to true, instances belonging to different groups are separated by putting them into individual parent cells. These parent cells are named after the groups and are put into the master top cell. If this property is set to false (the default), no such group parents will be formed. This property has been added in version 0.27.

Python specific notes:
The object exposes a readable attribute 'separate_groups'. This is the getter.

separate_groups=

Signature: void **separate_groups=** (bool flag)

Description: Sets a value indicating whether to create separate parent cells for individual groups.

See separate_groups for details about this property.

This property has been added in version 0.27.

Python specific notes:
The object exposes a writable attribute 'separate_groups'. This is the setter.

set_fills_datatype_per_mask

Signature: void **set_fills_datatype_per_mask** (unsigned int mask, int datatype)

Description: Sets the fill geometry layer datatype value.

See produce_via_geometry for details about the layer production rules.The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...).

Mask specific rules have been introduced in version 0.27.

set_fills_suffix_per_mask

Signature: void **set_fills_suffix_per_mask** (unsigned int mask, string suffix)

Description: Sets the fill geometry layer name suffix per mask.

See produce_via_geometry for details about the layer production rules.The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...).

	Mask specific rules have been introduced in version 0.27.
set_lef_pins_datatype_per_mas	**Signature**: void **set_lef_pins_datatype_per_mask** (unsigned int mask, int datatype) **Description**: Sets the LEF pin geometry layer datatype value. See produce_via_geometry for details about the layer production rules.The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...). Mask specific rules have been introduced in version 0.27.
set_lef_pins_suffix_per_mask	**Signature**: void **set_lef_pins_suffix_per_mask** (unsigned int mask, string suffix) **Description**: Sets the LEF pin geometry layer name suffix per mask. See produce_via_geometry for details about the layer production rules.The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...). Mask specific rules have been introduced in version 0.27.
set_pins_datatype_per_mask	**Signature**: void **set_pins_datatype_per_mask** (unsigned int mask, int datatype) **Description**: Sets the pin geometry layer datatype value. See produce_via_geometry for details about the layer production rules.The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...). Mask specific rules have been introduced in version 0.27.
set_pins_suffix_per_mask	**Signature**: void **set_pins_suffix_per_mask** (unsigned int mask, string suffix) **Description**: Sets the pin geometry layer name suffix per mask. See produce_via_geometry for details about the layer production rules.The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...). Mask specific rules have been introduced in version 0.27.
set_routing_datatype_per_mas	**Signature**: void **set_routing_datatype_per_mask** (unsigned int mask, int datatype) **Description**: Sets the routing geometry layer datatype value. See produce_via_geometry for details about the layer production rules.The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...). Mask specific rules have been introduced in version 0.27.
set_routing_suffix_per_mask	**Signature**: void **set_routing_suffix_per_mask** (unsigned int mask, string suffix) **Description**: Sets the routing geometry layer name suffix per mask. See produce_via_geometry for details about the layer production rules.The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...). Mask specific rules have been introduced in version 0.27.
set_special_routing_datatype_p	**Signature**: void **set_special_routing_datatype_per_mask** (unsigned int mask, int datatype) **Description**: Sets the special routing geometry layer datatype value. See produce_via_geometry for details about the layer production rules.The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...). Mask specific rules have been introduced in version 0.27.
set_special_routing_suffix_per_mask	**Signature**: void **set_special_routing_suffix_per_mask** (unsigned int mask, string suffix) **Description**: Sets the special routing geometry layer name suffix per mask.

	See produce_via_geometry for details about the layer production rules.The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...). Mask specific rules have been introduced in version 0.27.
set_via_geometry_datatype_pe	**Signature**: void **set_via_geometry_datatype_per_mask** (unsigned int mask, int datatype) **Description**: Sets the via geometry layer datatype value. See produce_via_geometry for details about this property. The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...). Mask specific rules have been introduced in version 0.27.
set_via_geometry_suffix_per_mask	**Signature**: void **set_via_geometry_suffix_per_mask** (unsigned int mask, string suffix) **Description**: Sets the via geometry layer name suffix per mask. See produce_via_geometry for details about this property. The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...). Mask specific rules have been introduced in version 0.27.
special_routing_datatype	**(1) Signature**: *[const]* int **special_routing_datatype** **Description**: Gets the special routing layer datatype value. See produce_via_geometry for details about the layer production rules. The differentiation between special and normal routing has been introduced in version 0.27. **Python specific notes:** The object exposes a readable attribute 'special_routing_datatype'. This is the getter. **(2) Signature**: *[const]* int **special_routing_datatype** (unsigned int mask) **Description**: Gets the special routing geometry layer datatype value per mask. See produce_via_geometry for details about the layer production rules.The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...). Mask specific rules have been introduced in version 0.27. **Python specific notes:** This method is available as 'special_routing_datatype_' in Python to distiguish it from the property with the same name.
special_routing_datatype=	**Signature**: void **special_routing_datatype=** (int datatype) **Description**: Sets the special routing layer datatype value. See produce_via_geometry for details about the layer production rules. The differentiation between special and normal routing has been introduced in version 0.27. **Python specific notes:** The object exposes a writable attribute 'special_routing_datatype'. This is the setter.
special_routing_suffix	**Signature**: *[const]* string **special_routing_suffix** **Description**: Gets the special routing layer name suffix. See produce_via_geometry for details about the layer production rules. The differentiation between special and normal routing has been introduced in version 0.27. **Python specific notes:** The object exposes a readable attribute 'special_routing_suffix'. This is the getter.

special_routing_suffix=

Signature: void **special_routing_suffix=** (string suffix)

Description: Sets the special routing layer name suffix.

See produce_via_geometry for details about the layer production rules. The differentiation between special and normal routing has been introduced in version 0.27.

Python specific notes:
The object exposes a writable attribute 'special_routing_suffix'. This is the setter.

special_routing_suffix_per_ma

Signature: *[const]* string **special_routing_suffix_per_mask** (unsigned int mask)

Description: Gets the special routing geometry layer name suffix per mask.

See produce_via_geometry for details about the layer production rules.The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...).

Mask specific rules have been introduced in version 0.27.

via_cellname_prefix

Signature: *[const]* string **via_cellname_prefix**

Description: Gets the via cellname prefix.

Vias are represented by cells. The cell name is formed by combining the via cell name prefix and the via name.

This property has been added in version 0.27.

Python specific notes:
The object exposes a readable attribute 'via_cellname_prefix'. This is the getter.

via_cellname_prefix=

Signature: void **via_cellname_prefix=** (string prefix)

Description: Sets the via cellname prefix.

See via_cellname_prefix for details about this property.

This property has been added in version 0.27.

Python specific notes:
The object exposes a writable attribute 'via_cellname_prefix'. This is the setter.

via_geometry_datatype

(1) Signature: *[const]* int **via_geometry_datatype**

Description: Gets the via geometry layer datatype value.

See produce_via_geometry for details about this property.

Python specific notes:
The object exposes a readable attribute 'via_geometry_datatype'. This is the getter.

(2) Signature: *[const]* int **via_geometry_datatype** (unsigned int mask)

Description: Gets the via geometry layer datatype value per mask.

See produce_via_geometry for details about this property. The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...).

Mask specific rules have been introduced in version 0.27.

Python specific notes:
This method is available as 'via_geometry_datatype_' in Python to distiguish it from the property with the same name.

via_geometry_datatype=

Signature: void **via_geometry_datatype=** (int datatype)

Description: Sets the via geometry layer datatype value.

See produce_via_geometry for details about this property.

	Python specific notes: The object exposes a writable attribute 'via_geometry_datatype'. This is the setter.
via_geometry_suffix	**Signature**: *[const]* string **via_geometry_suffix** **Description**: Gets the via geometry layer name suffix. See produce_via_geometry for details about this property. **Python specific notes:** The object exposes a readable attribute 'via_geometry_suffix'. This is the getter.
via_geometry_suffix=	**Signature**: void **via_geometry_suffix=** (string suffix) **Description**: Sets the via geometry layer name suffix. See produce_via_geometry for details about this property. **Python specific notes:** The object exposes a writable attribute 'via_geometry_suffix'. This is the setter.
via_geometry_suffix_per_mask	**Signature**: *[const]* string **via_geometry_suffix_per_mask** (unsigned int mask) **Description**: Gets the via geometry layer name suffix per mask. See produce_via_geometry for details about this property. The mask number is a zero-based mask index (0: MASK 1, 1: MASK 2 ...). Mask specific rules have been introduced in version 0.27.

4.235. API reference - Class NetTracerConnectionInfo

Notation used in Ruby API documentation

Module: db

Description: Represents a single connection info line for the net tracer technology definition

This class has been introduced in version 0.28.3.

Public constructors

new NetTracerConnectionInfo ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const NetTracer(other)	Assigns another object to self
[const]	new NetTracerConnectionInfo ptr	**dup**		Creates a copy of self
[const]	string	**layer_a**		Gets the expression for the A layer
[const]	string	**layer_b**		Gets the expression for the B layer
[const]	string	**via_layer**		Gets the expression for the Via layer

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const NetTracerConnectionInfo other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new NetTracerConnectionInfo ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

layer_a

Signature: *[const]* string **layer_a**

Description: Gets the expression for the A layer

layer_b

Signature: *[const]* string **layer_b**

Description: Gets the expression for the B layer

new

Signature: *[static]* new NetTracerConnectionInfo ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

via_layer

Signature: *[const]* string **via_layer**

Description: Gets the expression for the Via layer

4.236. API reference - Class NetTracerSymbolInfo

Notation used in Ruby API documentation

Module: db

Description: Represents a single symbol info line for the net tracer technology definition

This class has been introduced in version 0.28.3.

Public constructors

new NetTracerSymbolInfo ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const NetTracer other)	Assigns another object to self
[const]	new NetTracerSymbolInfo ptr	**dup**		Creates a copy of self
[const]	string	**expression**		Gets the expression
[const]	string	**symbol**		Gets the symbol

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const NetTracerSymbolInfo other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new NetTracerSymbolInfo ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

expression

Signature: *[const]* string **expression**

Description: Gets the expression

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new NetTracerSymbolInfo ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

symbol

Signature: *[const]* string **symbol**

Description: Gets the symbol

4.237. API reference - Class NetTracerConnectivity

Notation used in Ruby API documentation

Module: db

Description: A connectivity description for the net tracer

This object represents the technology description for the net tracer (represented by the NetTracer class). A technology description basically consists of connection declarations. A connection is given by either two or three expressions describing two conductive materials. With two expressions, the connection describes a transition from one material to another one. With three expressions, the connection describes a transition from one material to another through a connection (a "via").

The conductive material is derived from original layers either directly or through boolean expressions. These expressions can include symbols which are defined through the symbol method.

For details about the expressions see the description of the net tracer feature.

This class has been introduced in version 0.28 and replaces the 'NetTracerTechnology' class which has been generalized.

Public constructors

new NetTracerConnectivity ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const NetTracerConne other)	Assigns another object to self
	void	**connection**	(string a, string b)	Defines a connection between two materials
	void	**connection**	(string a, string via, string b)	Defines a connection between materials through a via
[const]	string	**description**		Gets the description text of the connectivty definition
	void	**description=**	(string d)	Sets the description of the connectivty definition
[const]	new NetTracerConnectivity ptr	**dup**		Creates a copy of self

[const,iter]	NetTracerConnectionIn	**each_connection**		Gets the connection information.
[const,iter]	NetTracerSymbolInfo	**each_symbol**		Gets the symbol information.
[const]	string	**name**		Gets the name of the connectivty definition
	void	**name=**	(string n)	Sets the name of the connectivty definition
	void	**symbol**	(string name, string expr)	Defines a symbol for use in the material expressions.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is

	known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required. Usually it's not required to call this method. It has been introduced in version 0.24.
_unmanage	**Signature**: void **_unmanage** **Description**: Marks the object as no longer owned by the script side. Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.
assign	**Signature**: void **assign** (const NetTracerConnectivity other) **Description**: Assigns another object to self
connection	**(1) Signature**: void **connection** (string a, string b) **Description**: Defines a connection between two materials See the class description for details about this method. **(2) Signature**: void **connection** (string a, string via, string b) **Description**: Defines a connection between materials through a via See the class description for details about this method.
create	**Signature**: void **create** **Description**: Ensures the C++ object is created Use of this method is deprecated. Use _create instead Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
description	**Signature**: *[const]* string **description** **Description**: Gets the description text of the connectivty definition The description is an optional string giving a human-readable description for this definition. **Python specific notes:** The object exposes a readable attribute 'description'. This is the getter.
description=	**Signature**: void **description=** (string d) **Description**: Sets the description of the connectivty definition **Python specific notes:** The object exposes a writable attribute 'description'. This is the setter.
destroy	**Signature**: void **destroy** **Description**: Explicitly destroys the object Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new NetTracerConnectivity ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

each_connection

Signature: *[const,iter]* NetTracerConnectionInfo **each_connection**

Description: Gets the connection information.

This iterator method has been introduced in version 0.28.3.

each_symbol

Signature: *[const,iter]* NetTracerSymbolInfo **each_symbol**

Description: Gets the symbol information.

This iterator method has been introduced in version 0.28.3.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

name

Signature: *[const]* string **name**

Description: Gets the name of the connectivty definition

The name is an optional string defining the formal name for this definition.

Python specific notes:
The object exposes a readable attribute 'name'. This is the getter.

name=

Signature: void **name=** (string n)

Description: Sets the name of the connectivty definition

Python specific notes:
The object exposes a writable attribute 'name'. This is the setter.

new

Signature: *[static]* new NetTracerConnectivity ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

symbol

Signature: void **symbol** (string name, string expr)

Description: Defines a symbol for use in the material expressions.

Defines a sub-expression to be used in further symbols or material expressions. For the detailed notation of the expression see the description of the net tracer feature.

4.238. API reference - Class NetTracerTechnologyComponent

Notation used in Ruby API documentation

Module: db

Description: Represents the technology information for the net tracer.

Class hierarchy: NetTracerTechnologyComponent » TechnologyComponent

This class has been redefined in version 0.28 and re-introduced in version 0.28.3. Since version 0.28, multiple stacks are supported and the individual stack definition is provided through a list of stacks. Use each to iterate the stacks.

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**add**	(const NetTracerConn connection)	Adds a connectivity definition.
	void	**assign**	(const NetTracerTechnologyComponent other)	Assigns another object to self
	void	**clear**		Removes all connectivity definitions.
[const]	new NetTracerTechnologyComponent ptr	**dup**		Creates a copy of self
[const,iter]	NetTracerConnectivity	**each**		Gets the connectivity definitions from the net tracer technology component.

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

add

Signature: void **add** (const NetTracerConnectivity connection)

Description: Adds a connectivity definition.

This method has been introduced in version 0.28.7

assign

Signature: void **assign** (const NetTracerTechnologyComponent other)

Description: Assigns another object to self

clear

Signature: void **clear**

Description: Removes all connectivity definitions.

This method has been introduced in version 0.28.7

dup

Signature: *[const]* new NetTracerTechnologyComponent ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

each

Signature: *[const,iter]* NetTracerConnectivity **each**

Description: Gets the connectivity definitions from the net tracer technology component.

Python specific notes:
This method enables iteration of the object.

4.239. API reference - Class NetElement

Notation used in Ruby API documentation

Module: db

Description: A net element for the NetTracer net tracing facility

This object represents a piece of a net extracted by the net tracer. See the description of NetTracer for more details about the net tracer feature.

The NetTracer object represents one shape of the net. The shape can be an original shape or a shape derived in a boolean operation. In the first case, the shape refers to a shape within a cell or a subcell of the original top cell. In the latter case, the shape is a synthesized one and outside the original layout hierarchy.

In any case, the shape method will deliver the shape and trans the transformation of the shape into the original top cell. To obtain a flat representation of the net, the shapes need to be transformed by this transformation.

layer will give the layer the shape is located at, cell_index will denote the cell that contains the shape.

This class has been introduced in version 0.25.

Public constructors

new NetElement ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const NetElem other)	Assigns another object to self
[const]	Box	**bbox**		Delivers the bounding box of the shape as seen from the original top cell
[const]	unsigned int	**cell_index**		Gets the index of the cell the shape is inside
[const]	new NetElement ptr	**dup**		Creates a copy of self
[const]	unsigned int	**layer**		Gets the index of the layer the shape is on
[const]	Shape	**shape**		Gets the shape that makes up this net element
[const]	ICplxTrans	**trans**		Gets the transformation to apply for rendering the shape in the original top cell

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void _**create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void _**destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool _**destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool _**is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void _**manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void _**unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method

will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const NetElement other)

Description: Assigns another object to self

bbox

Signature: *[const]* Box **bbox**

Description: Delivers the bounding box of the shape as seen from the original top cell

cell_index

Signature: *[const]* unsigned int **cell_index**

Description: Gets the index of the cell the shape is inside

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new NetElement ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

layer	**Signature**: *[const]* unsigned int **layer** **Description**: Gets the index of the layer the shape is on
new	**Signature**: *[static]* new NetElement ptr **new** **Description**: Creates a new object of this class **Python specific notes:** This method is the default initializer of the object.
shape	**Signature**: *[const]* Shape **shape** **Description**: Gets the shape that makes up this net element See the class description for more details about this attribute.
trans	**Signature**: *[const]* ICplxTrans **trans** **Description**: Gets the transformation to apply for rendering the shape in the original top cell See the class description for more details about this attribute.

4.240. API reference - Class NetTracer

Notation used in Ruby API documentation

Module: db

Description: The net tracer feature

The net tracer class provides an interface to the net tracer feature. It is accompanied by the NetElement and NetTracerTechnology classes. The latter will provide the technology definition for the net tracer while the NetElement objects represent a piece of the net after it has been extracted.

The technology definition is optional. The net tracer can be used with a predefined technology as well. The basic scheme of using the net tracer is to instantiate a net tracer object and run the extraction through the NetTracer#trace method. After this method was executed successfully, the resulting net can be obtained from the net tracer object by iterating over the NetElement objects of the net tracer.

Here is some sample code:

```
ly = RBA::CellView::active.layout

tracer = RBA::NetTracer::new

tech = RBA::NetTracerConnectivity::new
tech.connection("1/0", "2/0", "3/0")

tracer.trace(tech, ly, ly.top_cell, RBA::Point::new(7000, 1500), ly.find_layer(1, 0))

tracer.each_element do |e|
  puts e.shape.polygon.transformed(e.trans)
end
```

This class has been introduced in version 0.25. With version 0.28, the NetTracerConnectivity class replaces the 'NetTracerTechnology' class.

Public constructors

new NetTracer ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const NetTracer other)	Assigns another object to self
	void	**clear**		Clears the data from the last extraction

[const]	new NetTracer ptr	**dup**		Creates a copy of self
[const,iter]	NetElement	**each_element**		Iterates over the elements found during extraction
[const]	bool	**incomplete?**		Returns a value indicating whether the net is incomplete
[const]	string	**name**		Returns the name of the net found during extraction
[const]	unsigned long	**num_elements**		Returns the number of elements found during extraction
	void	**trace**	(const NetTracerConnectivity tech, const Layout layout, const Cell cell, const Point start_point, unsigned int start_layer)	Runs a net extraction
	void	**trace**	(const NetTracerConnectivity tech, const Layout layout, const Cell cell, const Point start_point, unsigned int start_layer, const Point stop_point, unsigned int stop_layer)	Runs a path extraction
	void	**trace**	(string tech, const Layout layout, const Cell cell, const Point start_point, unsigned int start_layer)	Runs a net extraction taking a predefined technology
	void	**trace**	(string tech, string connectivity_name, const Layout layout, const Cell cell, const Point start_point, unsigned int start_layer)	Runs a net extraction taking a predefined technology
	void	**trace**	(string tech, const Layout layout, const Cell cell, const Point start_point, unsigned int start_layer, const Point stop_point, unsigned int stop_layer)	Runs a path extraction taking a predefined technology
	void	**trace**	(string tech, string connectivity_name, const Layout layout, const Cell cell, const Point start_point, unsigned int start_layer, const Point stop_point,	Runs a path extraction taking a predefined technology

			unsigned int stop_layer)	
[const]	unsigned long	**trace_depth**		gets the trace depth
	void	**trace_depth=**	(unsigned long n)	Sets the trace depth (shape limit)

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const NetTracer other)

Description: Assigns another object to self

clear

Signature: void **clear**

Description: Clears the data from the last extraction

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new NetTracer ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

each_element

Signature: *[const,iter]* NetElement **each_element**

Description: Iterates over the elements found during extraction

The elements are available only after the extraction has been performed.

incomplete?

Signature: *[const]* bool **incomplete?**

Description: Returns a value indicating whether the net is incomplete

A net may be incomplete if the extraction has been stopped by the user for example. This attribute is useful only after the extraction has been performed.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

name

Signature: *[const]* string **name**

Description: Returns the name of the net found during extraction

The net name is extracted from labels found during the extraction. This attribute is useful only after the extraction has been performed.

new

Signature: *[static]* new NetTracer ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

num_elements

Signature: *[const]* unsigned long **num_elements**

Description: Returns the number of elements found during extraction

This attribute is useful only after the extraction has been performed.

trace

(1) Signature: void **trace** (const NetTracerConnectivity tech, const Layout layout, const Cell cell, const Point start_point, unsigned int start_layer)

Description: Runs a net extraction

tech:	The connectivity definition
layout:	The layout on which to run the extraction
cell:	The cell on which to run the extraction (child cells will be included)
start_point:	The start point from which to start extraction of the net
start_layer:	The layer from which to start extraction

This method runs an extraction with the given parameters. To make the extraction successful, a shape must be present at the given start point on the start layer. The start layer must be a valid layer mentioned within the technology specification.

This version runs a single extraction - i.e. it will extract all elements connected to the given seed point. A path extraction version is provided as well which will extract one (the presumably shortest) path between two points.

(2) Signature: void **trace** (const NetTracerConnectivity tech, const Layout layout, const Cell cell, const Point start_point, unsigned int start_layer, const Point stop_point, unsigned int stop_layer)

Description: Runs a path extraction

tech:	The connectivity definition
layout:	The layout on which to run the extraction
cell:	The cell on which to run the extraction (child cells will be included)

start_point:	The start point from which to start extraction of the net
start_layer:	The layer from which to start extraction
stop_point:	The stop point at which to stop extraction of the net
stop_layer:	The layer at which to stop extraction

This method runs an path extraction with the given parameters. To make the extraction successful, a shape must be present at the given start point on the start layer and at the given stop point at the given stop layer. The start and stop layers must be a valid layers mentioned within the technology specification.

This version runs a path extraction and will deliver elements forming one path leading from the start to the end point.

(3) Signature: void **trace** (string tech, const Layout layout, const Cell cell, const Point start_point, unsigned int start_layer)

Description: Runs a net extraction taking a predefined technology

This method behaves identical as the version with a technology object, except that it will look for a technology with the given name to obtain the extraction setup. The technology is looked up by technology name. A version of this method exists where it is possible to specify the name of the particular connectivity to use in case there are multiple definitions available.

(4) Signature: void **trace** (string tech, string connectivity_name, const Layout layout, const Cell cell, const Point start_point, unsigned int start_layer)

Description: Runs a net extraction taking a predefined technology

This method behaves identical as the version with a technology object, except that it will look for a technology with the given name to obtain the extraction setup. This version allows specifying the name of the connecvitiy setup.

This method variant has been introduced in version 0.28.

(5) Signature: void **trace** (string tech, const Layout layout, const Cell cell, const Point start_point, unsigned int start_layer, const Point stop_point, unsigned int stop_layer)

Description: Runs a path extraction taking a predefined technology

This method behaves identical as the version with a technology object, except that it will look for a technology with the given name to obtain the extraction setup.

(6) Signature: void **trace** (string tech, string connectivity_name, const Layout layout, const Cell cell, const Point start_point, unsigned int start_layer, const Point stop_point, unsigned int stop_layer)

Description: Runs a path extraction taking a predefined technology

This method behaves identical as the version with a technology object, except that it will look for a technology with the given name to obtain the extraction setup.This version allows specifying the name of the connecvitiy setup.

This method variant has been introduced in version 0.28.

trace_depth

Signature: *[const]* unsigned long **trace_depth**

Description: gets the trace depth

See trace_depth= for a description of this property.

This method has been introduced in version 0.26.4.

Python specific notes:
The object exposes a readable attribute 'trace_depth'. This is the getter.

trace_depth=

Signature: void **trace_depth=** (unsigned long n)

Description: Sets the trace depth (shape limit)

Set this value to limit the maximum number of shapes delivered. Upon reaching this count, the tracer will stop and report the net as 'incomplete' (see incomplete?). Setting a trace depth if 0 is equivalent to 'unlimited'. The actual number of shapes delivered may be a little less than the depth because of internal marker shapes which are taken into account, but are not delivered.

This method has been introduced in version 0.26.4.

Python specific notes:
The object exposes a writable attribute 'trace_depth'. This is the setter.

4.241. API reference - Class D25View

Notation used in Ruby API documentation

Module: lay

Description: The 2.5d View Dialog

Class hierarchy: D25View » QDialog » QWidget » QObject

This class is used internally to implement the 2.5d feature.

This class has been introduced in version 0.28.

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**begin**	(string generator)	Initiates delivery of display groups
	void	**clear**		Clears all display entries in the view
	void	**close**		Closes the view
	void	**close_display**		Finishes the display group
	void	**entry**	(const Region data, double dbu, double zstart, double zstop)	Creates a new display entry in the group opened with open_display
	void	**entry**	(const Edges data, double dbu, double zstart, double zstop)	Creates a new display entry in the group opened with open_display
	void	**entry**	(const EdgePairs data, double dbu, double zstart, double zstop)	Creates a new display entry in the group opened with open_display
	void	**finish**		Finishes the view - call this after the display groups have been created
	void	**open_display**	(unsigned int ptr frame_color,	Creates a new display group

unsigned int ptr
fill_color,
const LayerInfo ptr
like,
string ptr name)

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

begin	**Signature**: void **begin** (string generator) **Description**: Initiates delivery of display groups
clear	**Signature**: void **clear** **Description**: Clears all display entries in the view
close	**Signature**: void **close** **Description**: Closes the view
close_display	**Signature**: void **close_display** **Description**: Finishes the display group
entry	**(1) Signature**: void **entry** (const Region data, double dbu, double zstart, double zstop) **Description**: Creates a new display entry in the group opened with open_display **(2) Signature**: void **entry** (const Edges data, double dbu, double zstart, double zstop) **Description**: Creates a new display entry in the group opened with open_display **(3) Signature**: void **entry** (const EdgePairs data, double dbu, double zstart, double zstop) **Description**: Creates a new display entry in the group opened with open_display
finish	**Signature**: void **finish** **Description**: Finishes the view - call this after the display groups have been created
open_display	**Signature**: void **open_display** (unsigned int ptr frame_color, unsigned int ptr fill_color, const LayerInfo ptr like, string ptr name) **Description**: Creates a new display group

4.242. API reference - Class PCellDeclarationHelper

Notation used in Ruby API documentation

Module: db

Description: A helper class to simplify the declaration of a PCell (Ruby version)

Class hierarchy: PCellDeclarationHelper » PCellDeclaration

This class provides adds some convenience to the PCell declaration based on PCellDeclaration. PCellDeclaration is a C++ object which is less convenient to use than a Ruby-based approach. In particular this class simplifies the declaration and use of parameters through accessor methods that are created automatically from the declaration of the parameters.

The basic usage of this class is the following:

```
# Derive your PCell from PCellDeclarationHelper
class MyPCell < RBA::PCellDeclarationHelper

  # initalize
  def initialize
    super
    # your initialization: add parameters with name, type, description and
    # optional other values
    param :p, TypeInt, "The parameter", :default => 1
    param :l, TypeLayer, "The layer", :default => RBA::LayerInfo::new(1, 0)
    # add other parameters ..
  end

  # reimplement display_text_impl
  def display_text_impl
    # implement the method here
  end

  # reimplement produce_impl
  def produce_impl
    # implement the method here
  end

  # optionally reimplement coerce_parameters_impl
  def coerce_parameters_impl
    # implement the method here
  end

end
```

An implementation of display_text_impl could look like this:

```
  def display_text_impl
    "We have p=#{p}"
  end
```

Because in the sample declaration above we have declared parameter "p" we can access the value of p inside the implementation simply by using the "p" method.

Similarily the produce_impl implementation could use code like the following. Please note that layout and cell are available to get the layout and cell. Also because we have declared a layer parameter "l", we can access the layer index with the "l_layer" method:

```
  def produce_impl
    cell.shapes(l_layer).insert(RBA::Box.new(0, 0, p*100, p*200))
```

```
end
```

Again in this sample, we used "p" to access the parameter "p".

The implementation of coerce_parameter_impl can make use of the parameter setters. In the case of the "p" parameter, the setter is "set_p":

```
def coerce_parameter_impl
  p < 10 || set_p(10)
end
```

Public methods

callback_impl		Provides a callback on a parameter change
callback_impl		Provides a callback on a parameter change
can_create_from_shape_impl		Returns true if the PCell can be created from the given shape
can_create_from_shape_impl		Returns true if the PCell can be created from the given shape
cell		Gets the reference to the current cell within produce_impl
cell		Gets the reference to the current cell within produce_impl
coerce_parameters_impl		Coerces the parameters
coerce_parameters_impl		Coerces the parameters
display_text_impl		Delivers the display text
display_text_impl		Delivers the display text
initialize		Initializes this instance
initialize		Initializes this instance
layer		Gets the reference to the current layer index within can_create_from_shape_impl, parameters_from_shape_impl and transformation_from_shape_impl
layer		Gets the reference to the current layer index within can_create_from_shape_impl, parameters_from_shape_impl and transformation_from_shape_impl
layout		Gets the reference to the current layout within produce_impl, can_create_from_shape_impl, parameters_from_shape_impl and transformation_from_shape_impl
layout		Gets the reference to the current layout within produce_impl, can_create_from_shape_impl, parameters_from_shape_impl and transformation_from_shape_impl
param	(name, type, descriptio	Declares a parameter with the given name, type and description and optional attributes.

	...)	
param	(name, type, description, ...)	Declares a parameter with the given name, type and description and optional attributes.
parameters_from_shape_impl		Sets the parameters from a shape
parameters_from_shape_impl		Sets the parameters from a shape
produce_impl		Produces the layout
produce_impl		Produces the layout
shape		Gets the reference to the current shape within can_create_from_shape_impl, parameters_from_shape_impl and transformation_from_shape_impl
shape		Gets the reference to the current shape within can_create_from_shape_impl, parameters_from_shape_impl and transformation_from_shape_impl
transformation_from_shape_imp		Gets the initial PCell instance transformation when creating from a shape
transformation_from_shape_impl		Gets the initial PCell instance transformation when creating from a shape

Detailed description

callback_impl

(1) Signature: **callback_impl**

Description: Provides a callback on a parameter change

This method applies to user interface changes only. Whenever a parameter is changed on the parameter page, this method is called with the name of the parameter.

On some occasions, this method called to establish a configuration unspecifically. In this case, the name is an empty string - indicating "all parameters may have changed".

This method can change the state of this or any other parameter. For this, the state objects are supplied instead of the parameter values. For example to enable parameter "b" when a boolean parameter "a" is true, use the following code:

```
def callback_impl(name)
  if name == "a" || name == ""
    b.enabled = a.value
  end
end
```

The "enabled" attribute of the PCellParameterState object indicates whether the parameter is enabled in the user interface. "a.value" delivers the value of the (boolean type assumed) parameter "a".

Note that the above code also checks for empty name to consider the case of a global refresh.

Further useful attributes of the parameters are:

- **enabled** : the parameter entry is grayed out if false

- **readonly** : the parameter cannot be edited (less strict than enabled)
- **visible** : the parameter entry is not visible if false
- **icon** : Sets an icon in front of the parameter indicating an error or a warning (use PCellParameterState#WarningIcon or PCellParameterState#ErrorIcon).

(2) Signature: **callback_impl**

Description: Provides a callback on a parameter change

This method applies to user interface changes only. Whenever a parameter is changed on the parameter page, this method is called with the name of the parameter.

On some occasions, this method called to establish a configuration unspecifically. In this case, the name is an empty string - indicating "all parameters may have changed".

This method can change the state of this or any other parameter. For this, the state objects are supplied instead of the parameter values. For example to enable parameter "b" when a boolean parameter "a" is true, use the following code:

```
def callback_impl(name)
  if name == "a" || name == ""
    b.enabled = a.value
  end
end
```

The "enabled" attribute of the PCellParameterState object indicates whether the parameter is enabled in the user interface. "a.value" delivers the value of the (boolean type assumed) parameter "a".

Note that the above code also checks for empty name to consider the case of a global refresh.

Further useful attributes of the parameters are:

- **enabled** : the parameter entry is grayed out if false
- **readonly** : the parameter cannot be edited (less strict than enabled)
- **visible** : the parameter entry is not visible if false
- **icon** : Sets an icon in front of the parameter indicating an error or a warning (use PCellParameterState#WarningIcon or PCellParameterState#ErrorIcon).

can_create_from_shape_impl

(1) Signature: **can_create_from_shape_impl**

Description: Returns true if the PCell can be created from the given shape

This method can be reimplemented in a PCell class. If the PCell can be created from the shape available through the shape accessor (a Shape object), this method is supposed to return true. The layout the shape lives in can be accessed with layout and the layer with layer.

The default implementation returns false.

(2) Signature: **can_create_from_shape_impl**

Description: Returns true if the PCell can be created from the given shape

This method can be reimplemented in a PCell class. If the PCell can be created from the shape available through the shape accessor (a Shape object), this method is supposed to return true. The layout the shape lives in can be accessed with layout and the layer with layer.

The default implementation returns false.

cell

(1) Signature: **cell**

Description: Gets the reference to the current cell within produce_impl

(2) Signature: **cell**

Description: Gets the reference to the current cell within produce_impl

coerce_parameters_impl

(1) Signature: **coerce_parameters_impl**

Description: Coerces the parameters

This method can be reimplemented in a PCell class. It is supposed to adjust parameters to render a consistent parameter set and to fix parameter range errors. This method is called for example inside the PCell user interface to compute the actual parameters when "Apply" is pressed.

(2) Signature: **coerce_parameters_impl**

Description: Coerces the parameters

This method can be reimplemented in a PCell class. It is supposed to adjust parameters to render a consistent parameter set and to fix parameter range errors. This method is called for example inside the PCell user interface to compute the actual parameters when "Apply" is pressed.

display_text_impl

(1) Signature: **display_text_impl**

Description: Delivers the display text

This method must be reimplemented in a PCell class to identify the PCell in human-readable form. This text is shown in the cell tree for the PCell for example.

(2) Signature: **display_text_impl**

Description: Delivers the display text

This method must be reimplemented in a PCell class to identify the PCell in human-readable form. This text is shown in the cell tree for the PCell for example.

initialize

(1) Signature: **initialize**

Description: Initializes this instance

(2) Signature: **initialize**

Description: Initializes this instance

layer

(1) Signature: **layer**

Description: Gets the reference to the current layer index within can_create_from_shape_impl, parameters_from_shape_impl and transformation_from_shape_impl

The object returned is the layer index within the Layout object of the shape which will be converted.

(2) Signature: **layer**

Description: Gets the reference to the current layer index within can_create_from_shape_impl, parameters_from_shape_impl and transformation_from_shape_impl

The object returned is the layer index within the Layout object of the shape which will be converted.

layout

(1) Signature: **layout**

Description: Gets the reference to the current layout within produce_impl, can_create_from_shape_impl, parameters_from_shape_impl and transformation_from_shape_impl

The object returned is the Layout object of the shape which will be converted.

(2) Signature: **layout**

Description: Gets the reference to the current layout within produce_impl, can_create_from_shape_impl, parameters_from_shape_impl and transformation_from_shape_impl

The object returned is the Layout object of the shape which will be converted.

param

(1) Signature: **param** (name, type, description, ...)

Description: Declares a parameter with the given name, type and description and optional attributes.

name:	The name of the parameter. Must be a simple word.
type:	The type. One of the Type... constants, that this class borrowed from PCellParameterDeclaration.
description:	The description text for this parameter

Optional, named parameters are

- **:hidden**: (boolean) true, if the parameter is not shown in the dialog
- **:readonly**: (boolean) true, if the parameter cannot be edited
- **:unit**: the unit string
- **:min_value**: the minimum value (effective for numerical types and if no choices are present)
- **:max_value**: the maximum value (effective for numerical types and if no choices are present)
- **:default**: the default value
- **:choices**: ([[d, v], ...]) choice descriptions/value for choice type

":choices" must be an array of two-element arrays (description text, value) which specify one choice each for parameters with a choice of values. Such parameters are represented by a drop-down box.

This declaration will create accessor methods "x" and "set_x", where "x" is the name of the parameter. If the type is TypeLayer, an accessor "x_layer" delivering the layer index inside produce_impl is created as well.

(2) Signature: **param** (name, type, description, ...)

Description: Declares a parameter with the given name, type and description and optional attributes.

name:	The name of the parameter. Must be a simple word.
type:	The type. One of the Type... constants, that this class borrowed from PCellParameterDeclaration.
description:	The description text for this parameter

Optional, named parameters are

- **:hidden**: (boolean) true, if the parameter is not shown in the dialog
- **:readonly**: (boolean) true, if the parameter cannot be edited
- **:unit**: the unit string
- **:min_value**: the minimum value (effective for numerical types and if no choices are present)
- **:max_value**: the maximum value (effective for numerical types and if no choices are present)
- **:default**: the default value
- **:choices**: ([[d, v], ...]) choice descriptions/value for choice type

":choices" must be an array of two-element arrays (description text, value) which specify one choice each for parameters with a choice of values. Such parameters are represented by a drop-down box.

This declaration will create accessor methods "x" and "set_x", where "x" is the name of the parameter. If the type is TypeLayer, an accessor "x_layer" delivering the layer index inside produce_impl is created as well.

parameters_from_shape_impl

(1) Signature: **parameters_from_shape_impl**

Description: Sets the parameters from a shape

This method can be reimplemented in a PCell class. If can_create_from_shape_impl returns true, this method is called to set the parameters from the given shape (see shape, layout and layer). Note, that for setting a layer parameter you need to create the LayerInfo object, i.e. like this:

```
set_l layout.get_info(layer)
```

The default implementation does nothing. All parameters not set in this method will receive their default value.

If you use a parameter called "layer" for example, the parameter getter will hide the "layer" argument. Use "_layer" for the argument in this case (same for "layout", "shape" or "cell):

```
set_layer layout.get_info(_layer)
```

(2) Signature: **parameters_from_shape_impl**

Description: Sets the parameters from a shape

This method can be reimplemented in a PCell class. If can_create_from_shape_impl returns true, this method is called to set the parameters from the given shape (see shape, layout and layer). Note, that for setting a layer parameter you need to create the LayerInfo object, i.e. like this:

```
set_l layout.get_info(layer)
```

The default implementation does nothing. All parameters not set in this method will receive their default value.

If you use a parameter called "layer" for example, the parameter getter will hide the "layer" argument. Use "_layer" for the argument in this case (same for "layout", "shape" or "cell):

```
set_layer layout.get_info(_layer)
```

produce_impl

(1) Signature: **produce_impl**

Description: Produces the layout

This method must be reimplemented in a PCell class. Using the parameter values provided by the parameter accessor methods and the layout and cell through layout and cell, this method is supposed to produce the final layout inside the given cell.

(2) Signature: **produce_impl**

Description: Produces the layout

This method must be reimplemented in a PCell class. Using the parameter values provided by the parameter accessor methods and the layout and cell through layout and cell, this method is supposed to produce the final layout inside the given cell.

shape

(1) Signature: **shape**

Description: Gets the reference to the current shape within can_create_from_shape_impl, parameters_from_shape_impl and transformation_from_shape_impl

The object returned is the Shape object of the shape which will be converted.

(2) Signature: **shape**

Description: Gets the reference to the current shape within can_create_from_shape_impl, parameters_from_shape_impl and transformation_from_shape_impl

The object returned is the Shape object of the shape which will be converted.

transformation_from_shape_impl

(1) Signature: **transformation_from_shape_impl**

Description: Gets the initial PCell instance transformation when creating from a shape

This method can be reimplemented in a PCell class. If can_create_from_shape_impl returns true, this method is called to get the initial transformation from the given shape (see shape, layout and layer).

This method must return a Trans object. The default implementation returns a unit transformation (no displacement, no rotation).

(2) Signature: **transformation_from_shape_impl**

Description: Gets the initial PCell instance transformation when creating from a shape

This method can be reimplemented in a PCell class. If can_create_from_shape_impl returns true, this method is called to get the initial transformation from the given shape (see shape, layout and layer).

This method must return a Trans object. The default implementation returns a unit transformation (no displacement, no rotation).

4.243. Class Index for Module db

KLayout classes

Box	A box class with integer coordinates
Cell	A cell
CellInstArray	A single or array cell instance
CellMapping	A cell mapping (source to target layout)
Circuit	Circuits are the basic building blocks of the netlist
CompoundRegionOperationNode	A base class for compound DRC operations
CompoundRegionOperationNode::GeometricalOp	This class represents the CompoundRegionOperationNode::GeometricalOp enum
CompoundRegionOperationNode::LogicalOp	This class represents the CompoundRegionOperationNode::LogicalOp enum
CompoundRegionOperationNode::ParameterType	This class represents the parameter type enum used in \CompoundRegionOperationNode#new_bbox_filter
CompoundRegionOperationNode::RatioParameterType	This class represents the parameter type enum used in \CompoundRegionOperationNode#new_ratio_filter
CompoundRegionOperationNode::ResultType	This class represents the CompoundRegionOperationNode::ResultType enum
Connectivity	This class specifies connections between different layers.
CplxTrans	A complex transformation
DBox	A box class with floating-point coordinates
DCellInstArray	A single or array cell instance in micrometer units
DCplxTrans	A complex transformation
DEdge	An edge class
DEdgePair	An edge pair (a pair of two edges)
DPath	A path class
DPoint	A point class with double (floating-point) coordinates
DPolygon	A polygon class
DSimplePolygon	A simple polygon class
DText	A text object
DTrans	A simple transformation

DVector	A vector class with double (floating-point) coordinates
DeepShapeStore	An opaque layout heap for the deep region processor
Device	A device inside a circuit.
DeviceAbstract	A geometrical device abstract
DeviceAbstractRef	Describes an additional device abstract reference for combined devices.
DeviceClass	A class describing a specific type of device.
DeviceClassBJT3Transistor	A device class for a bipolar transistor.
DeviceClassBJT4Transistor	A device class for a 4-terminal bipolar transistor.
DeviceClassCapacitor	A device class for a capacitor.
DeviceClassCapacitorWithBulk	A device class for a capacitor with a bulk terminal (substrate, well).
DeviceClassDiode	A device class for a diode.
DeviceClassFactory	A factory for creating specific device classes for the standard device extractors
DeviceClassInductor	A device class for an inductor.
DeviceClassMOS3Transistor	A device class for a 3-terminal MOS transistor.
DeviceClassMOS4Transistor	A device class for a 4-terminal MOS transistor.
DeviceClassResistor	A device class for a resistor.
DeviceClassResistorWithBulk	A device class for a resistor with a bulk terminal (substrate, well).
DeviceExtractorBJT3Transistor	A device extractor for a bipolar transistor (BJT)
DeviceExtractorBJT4Transistor	A device extractor for a four-terminal bipolar transistor (BJT)
DeviceExtractorBase	The base class for all device extractors.
DeviceExtractorCapacitor	A device extractor for a two-terminal capacitor
DeviceExtractorCapacitorWithBulk	A device extractor for a capacitor with a bulk terminal
DeviceExtractorDiode	A device extractor for a planar diode
DeviceExtractorMOS3Transistor	A device extractor for a three-terminal MOS transistor
DeviceExtractorMOS4Transistor	A device extractor for a four-terminal MOS transistor
DeviceExtractorResistor	A device extractor for a two-terminal resistor
DeviceExtractorResistorWithBulk	A device extractor for a resistor with a bulk terminal
DeviceParameterDefinition	A parameter descriptor
DeviceReconnectedTerminal	Describes a terminal rerouting in combined devices.

DeviceTerminalDefinition	A terminal descriptor
Edge	An edge class
EdgeFilter	A generic edge filter adaptor
EdgeMode	This class represents the edge mode type for \Region#edges.
EdgeOperator	A generic edge-to-polygon operator
EdgePair	An edge pair (a pair of two edges)
EdgePairFilter	A generic edge pair filter adaptor
EdgePairOperator	A generic edge-pair operator
EdgePairToEdgeOperator	A generic edge-pair-to-edge operator
EdgePairToPolygonOperator	A generic edge-pair-to-polygon operator
EdgePairs	EdgePairs (a collection of edge pairs)
EdgeProcessor	The edge processor (boolean, sizing, merge)
EdgeToEdgePairOperator	A generic edge-to-edge-pair operator
EdgeToPolygonOperator	A generic edge-to-polygon operator
Edges	A collection of edges (Not necessarily describing closed contours)
Edges::EdgeType	This enum specifies the edge type for edge angle filters.
EqualDeviceParameters	A device parameter equality comparer.
GenericDeviceCombiner	A class implementing the combination of two devices (parallel or serial mode).
GenericDeviceExtractor	The basic class for implementing custom device extractors.
GenericDeviceParameterCompare	A class implementing the comparison of device parameters.
GenericNetlistCompareLogger	An event receiver for the netlist compare feature.
HAlign	This class represents the horizontal alignment modes.
ICplxTrans	A complex transformation
IMatrix2d	A 2d matrix object used mainly for representing rotation and shear transformations (integer coordinate version).
IMatrix3d	A 3d matrix object used mainly for representing rotation, shear, displacement and perspective transformations (integer coordinate version).
InstElement	An element in an instantiation path
Instance	An instance proxy
LEFDEFReaderConfiguration	Detailed LEF/DEF reader options

LayerInfo	A structure encapsulating the layer properties
LayerMap	An object representing an arbitrary mapping of physical layers to logical layers
LayerMapping	A layer mapping (source to target layout)
Layout	The layout object
LayoutDiff	The layout compare tool
LayoutMetaInfo	A piece of layout meta information
LayoutQuery	A layout query
LayoutQueryIterator	Provides the results of the query
LayoutToNetlist	A generic framework for extracting netlists from layouts
LayoutToNetlist::BuildNetHierarchyMode	This class represents the LayoutToNetlist::BuildNetHierarchyMode enum
LayoutVsSchematic	A generic framework for doing LVS (layout vs. schematic)
Library	A Library
LoadLayoutOptions	Layout reader options
LoadLayoutOptions::CellConflictResolution	This enum specifies how cell conflicts are handled if a layout read into another layout and a cell name conflict arises.
LogEntryData	A generic log entry
Manager	A transaction manager class
Matrix2d	A 2d matrix object used mainly for representing rotation and shear transformations.
Matrix3d	A 3d matrix object used mainly for representing rotation, shear, displacement and perspective transformations.
Metrics	This class represents the metrics type for \Region#width and related checks.
Net	A single net.
NetElement	A net element for the NetTracer net tracing facility
NetPinRef	A connection to an outgoing pin of the circuit.
NetSubcircuitPinRef	A connection to a pin of a subcircuit.
NetTerminalRef	A connection to a terminal of a device.
NetTracer	The net tracer feature
NetTracerConnectionInfo	Represents a single connection info line for the net tracer technology definition
NetTracerConnectivity	A connectivity description for the net tracer

NetTracerSymbolInfo	Represents a single symbol info line for the net tracer technology definition
NetTracerTechnologyComponent	Represents the technology information for the net tracer.
Netlist	The netlist top-level class
NetlistCompareLogger	A base class for netlist comparer event receivers
NetlistComparer	Compares two netlists
NetlistCrossReference	Represents the identity mapping between the objects of two netlists.
NetlistCrossReference::CircuitPairData	A circuit match entry.
NetlistCrossReference::DevicePairData	A device match entry.
NetlistCrossReference::NetPairData	A net match entry.
NetlistCrossReference::NetPinRefPair	A match entry for a net pin pair.
NetlistCrossReference::NetSubcircuitPinRefPair	A match entry for a net subcircuit pin pair.
NetlistCrossReference::NetTerminalRefPair	A match entry for a net terminal pair.
NetlistCrossReference::PinPairData	A pin match entry.
NetlistCrossReference::Status	This class represents the NetlistCrossReference::Status enum
NetlistCrossReference::SubCircuitPairData	A subcircuit match entry.
NetlistDeviceExtractorLayerDefinition	Describes a layer used in the device extraction
NetlistObject	The base class for some netlist objects.
NetlistReader	Base class for netlist readers
NetlistSpiceReader	Implements a netlist Reader for the SPICE format.
NetlistSpiceReaderDelegate	Provides a delegate for the SPICE reader for translating device statements
NetlistSpiceWriter	Implements a netlist writer for the SPICE format.
NetlistSpiceWriterDelegate	Provides a delegate for the SPICE writer for doing special formatting for devices
NetlistWriter	Base class for netlist writers
PCellDeclaration	A PCell declaration providing the parameters and code to produce the PCell
PCellDeclarationHelper	A helper class to simplify the declaration of a PCell (Python version)
PCellDeclarationHelper	A helper class to simplify the declaration of a PCell (Ruby version)
PCellParameterDeclaration	A PCell parameter declaration
PCellParameterState	Provides access to the attributes of a single parameter within \PCellParameterStates.

PCellParameterState::ParameterStateIcon	This enum specifies the icon shown next to the parameter in PCell parameter list.
PCellParameterStates	Provides access to the parameter states inside a 'callback' implementation of a PCell
ParentInstArray	A parent instance
ParseElementComponentsData	Supplies the return value for \NetlistSpiceReaderDelegate#parse_element_components.
ParseElementData	Supplies the return value for \NetlistSpiceReaderDelegate#parse_element.
Path	A path class
Pin	A pin of a circuit.
Point	An integer point class
Polygon	A polygon class
PolygonFilter	A generic polygon filter adaptor
PolygonOperator	A generic polygon operator
PolygonToEdgeOperator	A generic polygon-to-edge operator
PolygonToEdgePairOperator	A generic polygon-to-edge-pair operator
PreferredOrientation	This class represents the PreferredOrientation enum used within polygon decomposition
PropertyConstraint	This class represents the property constraint for boolean and check functions.
RecursiveInstanceIterator	An iterator delivering instances recursively
RecursiveShapeIterator	An iterator delivering shapes recursively
Region	A region (a potentially complex area consisting of multiple polygons)
Region::OppositeFilter	This class represents the opposite error filter mode for \Region#separation and related checks.
Region::RectFilter	This class represents the error filter mode on rectangles for \Region#separation and related checks.
SaveLayoutOptions	Options for saving layouts
Severity	This enum specifies the severity level for log entries.
Shape	An object representing a shape in the layout database
ShapeCollection	A base class for the shape collections (\Region, \Edges, \EdgePairs and \Texts)
ShapeProcessor	The shape processor (boolean, sizing, merge on shapes)

Shapes	A collection of shapes
SimplePolygon	A simple polygon class
SubCircuit	A subcircuit inside a circuit.
Technology	Represents a technology
TechnologyComponent	A part of a technology definition
Text	A text object
TextFilter	A generic text filter adaptor
TextGenerator	A text generator class
TextOperator	A generic text operator
TextToPolygonOperator	A generic text-to-polygon operator
Texts	Texts (a collection of texts)
TileOutputReceiver	A receiver abstraction for the tiling processor.
TilingProcessor	A processor for layout which distributes tasks over tiles
Trans	A simple transformation
TrapezoidDecompositionMode	This class represents the TrapezoidDecompositionMode enum used within trapezoid decomposition
Utils	This namespace provides a collection of utility functions
VAlign	This class represents the vertical alignment modes.
VCplxTrans	A complex transformation
Vector	A integer vector class
ZeroDistanceMode	This class represents the zero_distance_mode type for \Region#width and related checks.

4.244. Class Index for Module lay

KLayout classes

AbstractMenu	An abstraction for the application menus
Action	The abstraction for an action (i.e. used inside menus)
Annotation	A layout annotation (i.e. ruler)
Application	The application object
BitmapBuffer	A simplistic pixel buffer representing monochrome image
BrowserDialog	A HTML display and browser dialog
BrowserPanel	A HTML display and browser widget
BrowserSource	The BrowserDialog's source for "int" URL's
ButtonState	The namespace for the button state flags in the mouse events of the Plugin class.
CellView	A class describing what is shown inside a layout view
Cursor	The namespace for the cursor constants
D25View	The 2.5d View Dialog
Dispatcher	Root of the configuration space in the plugin context and menu dispatcher
FileDialog	Various methods to request a file name
HelpDialog	The help dialog
HelpSource	A BrowserSource implementation delivering the help text for the help dialog
Image	An image to be stored as a layout annotation
ImageDataMapping	A structure describing the data mapping of an image object
InputDialog	Various methods to open a dialog requesting data entry
KeyCode	The namespace for the some key codes.
LayerProperties	The layer properties structure
LayerPropertiesIterator	Layer properties iterator
LayerPropertiesNode	A layer properties node structure
LayerPropertiesNodeRef	A class representing a reference to a layer properties node
LayoutView	The view object presenting one or more layout objects
LayoutView::SelectionMode	Specifies how selected objects interact with already selected ones.

LayoutViewWidget	
Macro	A macro class
Macro::Format	Specifies the format of a macro
Macro::Interpreter	Specifies the interpreter used for executing a macro
MacroExecutionContext	Support for various debugger features
MacroInterpreter	A custom interpreter for a DSL (domain specific language)
MainWindow	The main application window and central controller object
Marker	The floating-point coordinate marker object
MessageBox	Various methods to display message boxes
NetlistBrowserDialog	Represents the netlist browser dialog.
NetlistObjectPath	An object describing the instantiation of a netlist object.
NetlistObjectsPath	An object describing the instantiation of a single netlist object or a pair of those.
ObjectInstPath	A class describing a selected shape or instance
PixelBuffer	A simplistic pixel buffer representing an image of ARGB32 or RGB32 values
Plugin	The plugin object
PluginFactory	The plugin framework's plugin factory object

4.245. Class Index for Module rdb

KLayout classes

RdbCategory	A category inside the report database
RdbCell	A cell inside the report database
RdbItem	An item inside the report database
RdbItemValue	A value object inside the report database
RdbReference	A cell reference inside the report database
ReportDatabase	The report database object

4.246. Class Index for Module tl

KLayout classes

AbsoluteProgress	A progress reporter counting progress in absolute units
AbstractProgress	The abstract progress reporter
EmptyClass	
Executable	A generic executable object
Expression	Evaluation of Expressions
ExpressionContext	Represents the context of an expression evaluation
GlobPattern	A glob pattern matcher
Interpreter	A generalization of script interpreters
Logger	A logger
Progress	A progress reporter
Recipe	A facility for providing reproducible recipes
RelativeProgress	A progress reporter counting progress in relative units
Timer	A timer (stop watch)
Value	Encapsulates a value (preferably a plain data type) in an object
