Please note that it is important that the database unit of the target layout is identical to the database unit of the source layout to achieve the desired results.This method also assumes that the target layout holds the same layers than the source layout. It will copy shapes to the same layers than they have been on the original layout. This method has been added in version 0.21.

(2) Signature: *[const]* unsigned int **clip_into** (unsigned int cell, Layout ptr target, const DBox box)

Description: Clips the given cell by the given rectangle and produce a new cell with the clip

cell: The cell index of the cell to clip
box: The clip box in micrometer units
target: The target layout
Returns: The index of the new cell in the target layout

This variant which takes a micrometer-unit box has been added in version 0.28.

(3) Signature: *[const]* Cell ptr **clip_into** (const Cell cell, Layout ptr target, const Box box)
Description: Clips the given cell by the given rectangle and produce a new cell with the clip

cell: The reference to the cell to clip
box: The clip box in database units
target: The target layout
Returns: The reference to the new cell in the target layout

This variant which takes cell references instead of cell indexes has been added in version 0.28.

(4) Signature: *[const]* Cell ptr **clip_into** (const Cell cell, Layout ptr target, const DBox box)
Description: Clips the given cell by the given rectangle and produce a new cell with the clip

cell: The reference to the cell to clip
box: The clip box in micrometer units
target: The target layout
Returns: The reference to the new cell in the target layout

This variant which takes a micrometer-unit box and cell references has been added in version 0.28.

convert_cell_to_static

Signature: unsigned int **convert_cell_to_static** (unsigned int cell_index)
Description: Converts a PCell or library cell to a usual (static) cell

Returns: The index of the new cell

This method will create a new cell which contains the static representation of the PCell or library proxy given by "cell_index". If that cell is not a PCell or library proxy, it won't be touched and the input cell index is returned.

This method has been added in version 0.23.

copy_layer

(1) Signature: void **copy_layer** (unsigned int src, unsigned int dest)
Description: Copies a layer

src: The layer index of the source layer.
dest: The layer index of the destination layer.

Copies a layer from the source to the destination layer. The destination layer is not cleared before, so that this method merges shapes from the source with the destination layer.

This method was introduced in version 0.19.

(2) Signature: void **copy_layer** (unsigned int src, unsigned int dest, unsigned int flags)
Description: Copies a layer (selected shape types only)

src: The layer index of the source layer.
dest: The layer index of the destination layer.

flags:	A combination of the shape type flags from Shapes, S... constants

Copies a layer from the source to the destination layer. The destination layer is not cleared before, so that this method merges shapes from the source with the destination layer.

This method variant has been introduced in version 0.28.9.

copy_meta_info

(1) Signature: void **copy_meta_info** (const Layout other)

Description: Copies the meta information from the other layout into this layout

See LayoutMetaInfo for details about cells and meta information. The meta information from this layout will be replaced by the meta information from the other layout.

This method has been introduced in version 0.28.16.

(2) Signature: void **copy_meta_info** (const Layout other, const CellMapping cm)

Description: Copies the meta information from the other layout into this layout for the cells given by the cell mapping

See LayoutMetaInfo for details about cells and meta information. This method will use the source/target cell pairs from the cell mapping object and merge the meta information from each source cell from the 'other' layout into the mapped cell inside self. This method can be used with 'copy_tree_shapes' and similar to copy meta information in addition to the shapes. All cell-specific keys in this layout will be replaced by the respective values from the other layout.

This method has been introduced in version 0.28.16.

copy_tree_shapes

(1) Signature: void **copy_tree_shapes** (const Layout source_layout, const CellMapping cell_mapping)

Description: Copies the shapes for all given mappings in the CellMapping object

source_layout:	The layout where to take the shapes from
cell_mapping:	The cell mapping object that determines how cells are identified between source and target layout

Provide a CellMapping object to specify pairs of cells which are mapped from the source layout to this layout. When constructing such a cell mapping object for example with CellMapping#for_multi_cells_full, use self as the target layout. During the cell mapping construction, the cell mapper will usually create a suitable target hierarchy already. After having completed the cell mapping, use copy_tree_shapes to copy over the shapes from the source to the target layout.

This method has been added in version 0.26.8.

(2) Signature: void **copy_tree_shapes** (const Layout source_layout, const CellMapping cell_mapping, const LayerMapping layer_mapping)

Description: Copies the shapes for all given mappings in the CellMapping object using the given layer mapping

source_layout:	The layout where to take the shapes from
cell_mapping:	The cell mapping object that determines how cells are identified between source and target layout
layer_mapping:	Specifies which layers are copied from the source layout to the target layout

Provide a CellMapping object to specify pairs of cells which are mapped from the source layout to this layout. When constructing such a cell mapping object for example with CellMapping#for_multi_cells_full, use self as the target layout. During the cell mapping construction, the cell mapper will usually create a suitable target hierarchy already. After having completed the cell mapping, use copy_tree_shapes to copy over the shapes from the source to the target layout.

This method has been added in version 0.26.8.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

create_cell

(1) Signature: Cell ptr **create_cell** (string name)

Description: Creates a cell with the given name

name:	The name of the cell to create
Returns:	The Cell object of the newly created cell.

If a cell with that name already exists, the unique name will be chosen for the new cell consisting of the given name plus a suitable suffix.

This method has been introduce in version 0.23 and replaces add_cell.

(2) Signature: Cell ptr **create_cell** (string pcell_name, map<string,variant> params)

Description: Creates a cell as a PCell variant for the PCell with the given name

pcell_name:	The name of the PCell and also the name of the cell to create
params:	The PCell parameters (key/value dictionary)
Returns:	The Cell object of the newly created cell or an existing cell if the PCell has already been used with these parameters.

PCells are instantiated by creating a PCell variant. A PCell variant is linked to the PCell and represents this PCell with a particular parameter set.

This method will look up the PCell by the PCell name and create a new PCell variant for the given parameters. If the PCell has already been instantiated with the same parameters, the original variant will be returned. Hence this method is not strictly creating a cell - only if the required variant has not been created yet.

The parameters are specified as a key/value dictionary with the names being the ones from the PCell declaration.

If no PCell with the given name exists, nil is returned.

This method has been introduce in version 0.24.

(3) Signature: Cell ptr **create_cell** (string name, string lib_name)

Description: Creates a cell with the given name

name:	The name of the library cell and the name of the cell to create
lib_name:	The name of the library where to take the cell from
Returns:	The Cell object of the newly created cell or an existing cell if the library cell has already been used in this layout.

Library cells are imported by creating a 'library proxy'. This is a cell which represents the library cell in the framework of the current layout. The library proxy is linked to the library and will be updated if the library cell is changed.

This method will look up the cell by the given name in the specified library and create a new library proxy for this cell. If the same library cell has already been used, the original library proxy is returned. Hence, strictly speaking this method does not always create a new cell but may return a reference to an existing cell.

If the library name is not valid, nil is returned.

This method has been introduce in version 0.24.

(4) Signature: Cell ptr **create_cell** (string pcell_name, string lib_name, map<string,variant> params)

Description: Creates a cell for a PCell with the given PCell name from the given library

pcell_name:	The name of the PCell and also the name of the cell to create
lib_name:	The name of the library where to take the PCell from
params:	The PCell parameters (key/value dictionary)
Returns:	The Cell object of the newly created cell or an existing cell if this PCell has already been used with the given parameters

This method will look up the PCell by the PCell name in the specified library and create a new PCell variant for the given parameters plus the library proxy. The parameters must be specified as a key/value dictionary with the names being the ones from the PCell declaration.

If no PCell with the given name exists or the library name is not valid, nil is returned. Note that this function - despite the name - may not always create a new cell, but return an existing cell if the PCell from the library has already been used with the given parameters.

This method has been introduce in version 0.24.

dbu

Signature: *[const]* double **dbu**

Description: Gets the database unit

The database unit is the value of one units distance in micrometers. For numerical reasons and to be compliant with the GDS2 format, the database objects use integer coordinates. The basic unit of these coordinates is the database unit. You can convert coordinates to micrometers by multiplying the integer value with the database unit. Typical values for the database unit are 0.001 micrometer (one nanometer).

Python specific notes:
The object exposes a readable attribute 'dbu'. This is the getter.

dbu=

Signature: void **dbu=** (double dbu)

Description: Sets the database unit

See dbu for a description of the database unit.

Python specific notes:
The object exposes a writable attribute 'dbu'. This is the setter.

delete_cell

Signature: void **delete_cell** (unsigned int cell_index)

Description: Deletes a cell

cell_index:	The index of the cell to delete

This deletes a cell but not the sub cells of the cell. These subcells will likely become new top cells unless they are used otherwise. All instances of this cell are deleted as well. Hint: to delete multiple cells, use "delete_cells" which is far more efficient in this case.

This method has been introduced in version 0.20.

delete_cell_rec

Signature: void **delete_cell_rec** (unsigned int cell_index)

Description: Deletes a cell plus all subcells

cell_index:	The index of the cell to delete

This deletes a cell and also all sub cells of the cell. In contrast to prune_cell, all cells are deleted together with their instances even if they are used otherwise.

This method has been introduced in version 0.20.

delete_cells

Signature: void **delete_cells** (unsigned int[] cell_index_list)

Description: Deletes multiple cells

cell_index_list: An array of cell indices of the cells to delete

This deletes the cells but not the sub cells of these cells. These subcells will likely become new top cells unless they are used otherwise. All instances of these cells are deleted as well.

This method has been introduced in version 0.20.

delete_layer

Signature: void **delete_layer** (unsigned int layer_index)

Description: Deletes a layer

layer_index: The index of the layer to delete.

This method frees the memory allocated for the shapes of this layer and remembers the layer's index for reuse when the next layer is allocated.

delete_property

Signature: void **delete_property** (variant key)

Description: Deletes the user property with the given key

This method is a convenience method that deletes the property with the given key. It does nothing if no property with that key exists. Using that method is more convenient than creating a new property set with a new ID and assigning that properties ID. This method may change the properties ID.

This method has been introduced in version 0.24.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new Layout ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

each_cell

Signature: *[iter]* Cell **each_cell**

Description: Iterates the unsorted cell list

each_cell_bottom_up

Signature: *[iter]* unsigned int **each_cell_bottom_up**

Description: Iterates the bottom-up sorted cell list

In bottom-up traversal a cell is not delivered before the last child cell of this cell has been delivered. The bottom-up iterator does not deliver cells but cell indices actually.

each_cell_top_down

Signature: *[iter]* unsigned int **each_cell_top_down**

Description: begin iterator of the top-down sorted cell list

The top-down cell list has the property of delivering all cells before they are instantiated. In addition the first cells are all top cells. There is at least one top cell. The top-down iterator does not deliver cells but cell indices actually.

each_meta_info

Signature: *[const,iter]* LayoutMetaInfo **each_meta_info**

Description: Iterates over the meta information of the layout

See LayoutMetaInfo for details about layouts and meta information.

This method has been introduced in version 0.25.

each_top_cell

Signature: *[iter]* unsigned int **each_top_cell**

Description: Iterates the top cells

A layout may have an arbitrary number of top cells. The usual case however is that there is one top cell.

end_changes

Signature: void **end_changes**

Description: Cancels the "in changes" state (see "start_changes")

error_layer

Signature: *[const]* unsigned int **error_layer**

Description: Returns the index of the error layer

The error layer is used to place error texts on it, for example when a PCell evaluation fails.

This method has been added in version 0.23.13.

find_layer

(1) Signature: variant **find_layer** (const LayerInfo info)

Description: Finds a layer with the given properties

If a layer with the given properties already exists, this method will return the index of that layer.If no such layer exists, it will return nil.

In contrast to layer, this method will also find layers matching by name only. For example:

```
# finds layer '17/0' and 'name (17/0)':
index = layout.find_layer(RBA::LayerInfo::new(17, 0))
# finds layer 'name' (first priority), but also 'name (17/0)' (second
 priority):
index = layout.find_layer(RBA::LayerInfo::new('name'))
# note that this will not match layer 'name (17/0)' and create a new name-
only layer:
index = layout.layer(RBA::LayerInfo::new('name'))
```

This method has been introduced in version 0.23 and has been extended to name queries in version 0.28.11.

(2) Signature: variant **find_layer** (string name)

Description: Finds a layer with the given name

If a layer with the given name already exists, this method will return the index of that layer.If no such layer exists, it will return nil.

In contrast to layer, this method will also find numbered layers if the name matches. For example:

```
# finds layer 'name' (first priority), but also 'name (17/0)' (second
 priority):
index = layout.find_layer('name')
# note that this will not match layer 'name (17/0)' and create a new name-
only layer:
index = layout.layer('name')
```

This method has been introduced in version 0.23 and has been extended to name queries in version 0.28.11.

(3) Signature: variant **find_layer** (int layer, int datatype)

Description: Finds a layer with the given layer and datatype number

If a layer with the given layer/datatype already exists, this method will return the index of that layer.If no such layer exists, it will return nil.

This method has been introduced in version 0.23.

(4) Signature: variant **find_layer** (int layer, int datatype, string name)

Description: Finds a layer with the given layer and datatype number and name

If a layer with the given layer/datatype/name already exists, this method will return the index of that layer.If no such layer exists, it will return nil.

This method has been introduced in version 0.23.

flatten

Signature: void **flatten** (unsigned int cell_index, int levels, bool prune)

Description: Flattens the given cell

cell_index:	The cell which should be flattened
levels:	The number of hierarchy levels to flatten (-1: all, 0: none, 1: one level etc.)
prune:	Set to true to remove orphan cells.

This method propagates all shapes and instances from the specified number of hierarchy levels below into the given cell. It also removes the instances of the cells from which the shapes came from, but does not remove the cells themselves if prune is set to false. If prune is set to true, these cells are removed if not used otherwise.

This method has been introduced in version 0.20.

flatten_into

Signature: void **flatten_into** (unsigned int source_cell_index, unsigned int target_cell_index, const ICplxTrans trans, int levels)

Description: Flattens the given cell into another cell

source_cell_index:	The source cell which should be flattened
target_cell_index:	The target cell into which the resulting objects are written

trans:	The transformation to apply on the output shapes and instances
levels:	The number of hierarchy levels to flatten (-1: all, 0: none, 1: one level etc.)

This method works like 'flatten', but allows specification of a target cell which can be different from the source cell plus a transformation which is applied for all shapes and instances in the target cell.

In contrast to the 'flatten' method, the source cell is not modified.

This method has been introduced in version 0.24.

get_info

Signature: *[const]* LayerInfo **get_info** (unsigned int index)

Description: Gets the info structure for a specified layer

If the layer index is not a valid layer index, an empty LayerProperties object will be returned.

guiding_shape_layer

Signature: *[const]* unsigned int **guiding_shape_layer**

Description: Returns the index of the guiding shape layer

The guiding shape layer is used to store guiding shapes for PCells.

This method has been added in version 0.22.

has_cell?

Signature: bool **has_cell?** (string name)

Description: Returns true if a cell with a given name exists

Returns true, if the layout has a cell with the given name

has_prop_id?

Signature: *[const]* bool **has_prop_id?**

Description: Returns true, if the layout has user properties

This method has been introduced in version 0.24.

insert

(1) Signature: void **insert** (unsigned int cell_index, int layer, const Region region)

Description: Inserts a region into the given cell and layer

If the region is (conceptionally) a flat region, it will be inserted into the cell's shapes list as a flat sequence of polygons. If the region is a deep (hierarchical) region, it will create a subhierarchy below the given cell and its shapes will be put into the respective cells. Suitable subcells will be picked for inserting the shapes. If a hierarchy already exists below the given cell, the algorithm will try to reuse this hierarchy.

This method has been introduced in version 0.26.

(2) Signature: void **insert** (unsigned int cell_index, int layer, const Edges edges)

Description: Inserts an edge collection into the given cell and layer

If the edge collection is (conceptionally) flat, it will be inserted into the cell's shapes list as a flat sequence of edges. If the edge collection is deep (hierarchical), it will create a subhierarchy below the given cell and its edges will be put into the respective cells. Suitable subcells will be picked for inserting the edges. If a hierarchy already exists below the given cell, the algorithm will try to reuse this hierarchy.

This method has been introduced in version 0.26.

(3) Signature: void **insert** (unsigned int cell_index, int layer, const EdgePairs edge_pairs)

Description: Inserts an edge pair collection into the given cell and layer

If the edge pair collection is (conceptionally) flat, it will be inserted into the cell's shapes list as a flat sequence of edge pairs. If the edge pair collection is deep (hierarchical), it will create a subhierarchy below the given cell and its edge pairs will be put into the respective cells. Suitable subcells will be picked for inserting the edge pairs. If a hierarchy already exists below the given cell, the algorithm will try to reuse this hierarchy.

This method has been introduced in version 0.27.

(4) Signature: void **insert** (unsigned int cell_index, int layer, const Texts texts)

Description: Inserts an text collection into the given cell and layer

If the text collection is (conceptionally) flat, it will be inserted into the cell's shapes list as a flat sequence of texts. If the text collection is deep (hierarchical), it will create a subhierarchy below the given cell and its texts will be put into the respective cells. Suitable subcells will be picked for inserting the texts. If a hierarchy already exists below the given cell, the algorithm will try to reuse this hierarchy.

This method has been introduced in version 0.27.

insert_layer

Signature: unsigned int **insert_layer** (const LayerInfo props)

Description: Inserts a new layer with the given properties

Returns: The index of the newly created layer

insert_layer_at

Signature: void **insert_layer_at** (unsigned int index, const LayerInfo props)

Description: Inserts a new layer with the given properties at the given index

This method will associate the given layer info with the given layer index. If a layer with that index already exists, this method will change the properties of the layer with that index. Otherwise a new layer is created.

insert_special_layer

Signature: unsigned int **insert_special_layer** (const LayerInfo props)

Description: Inserts a new special layer with the given properties

Returns: The index of the newly created layer

Special layers can be used to represent objects that should not participate in normal viewing or other related operations. Special layers are not reported as valid layers.

insert_special_layer_at

Signature: void **insert_special_layer_at** (unsigned int index, const LayerInfo props)

Description: Inserts a new special layer with the given properties at the given index

See insert_special_layer for a description of special layers.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_editable?

Signature: *[const]* bool **is_editable?**

Description: Returns a value indicating whether the layout is editable.

Returns: True, if the layout is editable.

If a layout is editable, in general manipulation methods are enabled and some optimizations are disabled (i.e. shape arrays are expanded).

This method has been introduced in version 0.22.

is_free_layer?

Signature: *[const]* bool **is_free_layer?** (unsigned int layer_index)

Description: Returns true, if a layer index is a free (unused) layer index

Returns: true, if this is the case

This method has been introduced in version 0.26.

is_special_layer?

Signature: *[const]* bool **is_special_layer?** (unsigned int layer_index)

Description: Returns true, if a layer index is a special layer index

Returns: true, if this is the case

is_valid_cell_index?

Signature: *[const]* bool **is_valid_cell_index?** (unsigned int cell_index)

Description: Returns true, if a cell index is a valid index

Returns: true, if this is the case

This method has been added in version 0.20.

is_valid_layer?

Signature: *[const]* bool **is_valid_layer?** (unsigned int layer_index)

Description: Returns true, if a layer index is a valid normal layout layer index

Returns: true, if this is the case

layer

(1) Signature: unsigned int **layer**

Description: Creates a new internal layer

This method will create a new internal layer and return the layer index for this layer. The layer does not have any properties attached to it. That means, it is not going to be saved to a layout file unless it is given database properties with set_info.

This method is equivalent to "layer(RBA::LayerInfo::new())".

This method has been introduced in version 0.25.

(2) Signature: unsigned int **layer** (const LayerInfo info)

Description: Finds or creates a layer with the given properties

If a layer with the given properties already exists, this method will return the index of that layer.If no such layer exists, a new one with these properties will be created and its index will be returned. If "info" is anonymous (info.anonymous? is true), a new layer will always be created.

This method has been introduced in version 0.23.

(3) Signature: unsigned int **layer** (string name)

Description: Finds or creates a layer with the given name

If a layer with the given name already exists, this method will return the index of that layer.If no such layer exists, a new one with this name will be created and its index will be returned.

This method has been introduced in version 0.23.

(4) Signature: unsigned int **layer** (int layer, int datatype)

Description: Finds or creates a layer with the given layer and datatype number

If a layer with the given layer/datatype already exists, this method will return the index of that layer.If no such layer exists, a new one with these properties will be created and its index will be returned.

This method has been introduced in version 0.23.

(5) Signature: unsigned int **layer** (int layer, int datatype, string name)

Description: Finds or creates a layer with the given layer and datatype number and name

If a layer with the given layer/datatype/name already exists, this method will return the index of that layer.If no such layer exists, a new one with these properties will be created and its index will be returned.

This method has been introduced in version 0.23.

layer_indexes

Signature: *[const]* unsigned int[] **layer_indexes**

Description: Gets a list of valid layer's indices

This method returns an array with layer indices representing valid layers.

This method has been introduced in version 0.19.

layer_indices

Signature: *[const]* unsigned int[] **layer_indices**

Description: Gets a list of valid layer's indices

Use of this method is deprecated. Use layer_indexes instead

This method returns an array with layer indices representing valid layers.

This method has been introduced in version 0.19.

layer_infos

Signature: *[const]* LayerInfo[] **layer_infos**

Description: Gets a list of valid layer's properties

The method returns an array with layer properties representing valid layers. The sequence and length of this list corresponds to that of layer_indexes.

This method has been introduced in version 0.25.

layers

Signature: *[const]* unsigned int **layers**

Description: Returns the number of layers

The number of layers reports the maximum (plus 1) layer index used so far. Not all of the layers with an index in the range of 0 to layers-1 needs to be a valid layer. These layers can be either valid, special or unused. Use is_valid_layer? and is_special_layer? to test for the first two states.

library

Signature: *[const]* Library ptr **library**

Description: Gets the library this layout lives in or nil if the layout is not part of a library

This attribute has been introduced in version 0.27.5.

merge_meta_info

(1) Signature: void **merge_meta_info** (const Layout other)

Description: Merges the meta information from the other layout into this layout

See LayoutMetaInfo for details about cells and meta information. Existing keys in this layout will be overwritten by the respective values from the other layout. New keys will be added.

This method has been introduced in version 0.28.16.

(2) Signature: void **merge_meta_info** (const Layout other, const CellMapping cm)

Description: Merges the meta information from the other layout into this layout for the cells given by the cell mapping

See LayoutMetaInfo for details about cells and meta information. This method will use the source/target cell pairs from the cell mapping object and merge the meta information from each source cell from the 'other' layout into the mapped cell inside self. This method can be used with 'copy_tree_shapes' and similar to copy meta information in addition to the shapes. Existing cell-specific keys in this layout will be overwritten by the respective values from the other layout. New keys will be added.

This method has been introduced in version 0.28.16.

meta_info

Signature: new LayoutMetaInfo ptr **meta_info** (string name)

Description: Gets the meta information for a given name

See LayoutMetaInfo for details about layouts and meta information.

If no meta information with the given name exists, nil is returned.

This method has been introduced in version 0.28.8.

meta_info_value

Signature: variant **meta_info_value** (string name)

Description: Gets the meta information value for a given name

See LayoutMetaInfo for details about layouts and meta information.

If no meta information with the given name exists, a nil value will be returned. A more generic version that delivers all fields of the meta information is meta_info.

This method has been introduced in version 0.25. Starting with version 0.28.8, the value is of variant type instead of string only.

move_layer

(1) Signature: void **move_layer** (unsigned int src, unsigned int dest)

Description: Moves a layer

src:	The layer index of the source layer.
dest:	The layer index of the destination layer.

Moves a layer from the source to the destination layer. The target is not cleared before, so that this method merges shapes from the source with the destination layer. The source layer is empty after that operation.

This method was introduced in version 0.19.

(2) Signature: void **move_layer** (unsigned int src, unsigned int dest, unsigned int flags)

Description: Moves a layer (selected shape types only)

src:	The layer index of the source layer.
dest:	The layer index of the destination layer.
flags:	A combination of the shape type flags from Shapes, S... constants

Moves a layer from the source to the destination layer. The target is not cleared before, so that this method merges shapes from the source with the destination layer. The copied shapes are removed from the source layer.

This method variant has been introduced in version 0.28.9.

move_tree_shapes

(1) Signature: void **move_tree_shapes** (Layout source_layout, const CellMapping cell_mapping)

Description: Moves the shapes for all given mappings in the CellMapping object

This method acts like the corresponding copy_tree_shapes method, but removes the shapes from the source layout after they have been copied.

This method has been added in version 0.26.8.

(2) Signature: void **move_tree_shapes** (Layout source_layout, const CellMapping cell_mapping, const LayerMapping layer_mapping)

Description: Moves the shapes for all given mappings in the CellMapping object using the given layer mapping

This method acts like the corresponding copy_tree_shapes method, but removes the shapes from the source layout after they have been copied.

This method has been added in version 0.26.8.

multi_clip

(1) Signature: unsigned int[] **multi_clip** (unsigned int cell, Box[] boxes)

Description: Clips the given cell by the given rectangles and produces new cells with the clips, one for each rectangle.

cell:	The cell index of the cell to clip
boxes:	The clip boxes in database units
Returns:	The indexes of the new cells

This method will cut rectangular regions given by the boxes from the given cell. The clips will be stored in a new cells whose indexed are returned. The clips will be performed hierarchically. The resulting cells will hold a hierarchy of child cells, which are potentially clipped versions of child cells of the original cell. This version is somewhat more efficient than doing individual clips because the clip cells may share clipped versions of child cells.

This method has been added in version 0.21.

(2) Signature: unsigned int[] **multi_clip** (unsigned int cell, DBox[] boxes)

Description: Clips the given cell by the given rectangles and produces new cells with the clips, one for each rectangle.

cell:	The cell index of the cell to clip
boxes:	The clip boxes in micrometer units
Returns:	The indexes of the new cells

This variant which takes micrometer-unit boxes has been added in version 0.28.

(3) Signature: Cell ptr[] **multi_clip** (const Cell cell, Box[] boxes)

Description: Clips the given cell by the given rectangles and produces new cells with the clips, one for each rectangle.

cell:	The reference to the cell to clip
boxes:	The clip boxes in database units
Returns:	The references to the new cells

This variant which takes cell references has been added in version 0.28.

(4) Signature: Cell ptr[] **multi_clip** (const Cell cell, DBox[] boxes)

Description: Clips the given cell by the given rectangles and produces new cells with the clips, one for each rectangle.

cell:	The reference to the cell to clip
boxes:	The clip boxes in micrometer units
Returns:	The references to the new cells

This variant which takes cell references and micrometer-unit boxes has been added in version 0.28.

multi_clip_into

(1) Signature: unsigned int[] **multi_clip_into** (unsigned int cell, Layout ptr target, Box[] boxes)

Description: Clips the given cell by the given rectangles and produces new cells with the clips, one for each rectangle.

cell:	The cell index of the cell to clip
boxes:	The clip boxes in database units
target:	The target layout
Returns:	The indexes of the new cells

This method will cut rectangular regions given by the boxes from the given cell. The clips will be stored in a new cells in the given target layout. The clips will be performed hierarchically. The resulting cells will hold a hierarchy of child cells, which are potentially clipped versions of child cells of the original cell. This version is somewhat more efficient than doing individual clips because the clip cells may share clipped versions of child cells.

Please note that it is important that the database unit of the target layout is identical to the database unit of the source layout to achieve the desired results. This method also assumes that the target layout holds the same layers than the source layout. It will copy shapes to the same layers than they have been on the original layout.

This method has been added in version 0.21.

(2) Signature: unsigned int[] **multi_clip_into** (unsigned int cell, Layout ptr target, DBox[] boxes)

Description: Clips the given cell by the given rectangles and produces new cells with the clips, one for each rectangle.

cell:	The cell index of the cell to clip
boxes:	The clip boxes in database units
target:	The target layout
Returns:	The indexes of the new cells

This variant which takes micrometer-unit boxes has been added in version 0.28.

(3) Signature: Cell ptr[] **multi_clip_into** (const Cell cell, Layout ptr target, Box[] boxes)

Description: Clips the given cell by the given rectangles and produces new cells with the clips, one for each rectangle.

cell:	The reference the cell to clip
boxes:	The clip boxes in database units
target:	The target layout
Returns:	The references to the new cells

This variant which takes cell references boxes has been added in version 0.28.

(4) Signature: Cell ptr[] **multi_clip_into** (const Cell cell, Layout ptr target, DBox[] boxes)

Description: Clips the given cell by the given rectangles and produces new cells with the clips, one for each rectangle.

cell:	The reference the cell to clip
boxes:	The clip boxes in micrometer units
target:	The target layout
Returns:	The references to the new cells

This variant which takes cell references and micrometer-unit boxes has been added in version 0.28.

new

(1) Signature: *[static]* new Layout ptr **new** (Manager manager)

Description: Creates a layout object attached to a manager

This constructor specifies a manager object which is used to store undo information for example.

Starting with version 0.25, layouts created with the default constructor are always editable. Before that version, they inherited the editable flag from the application.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new Layout ptr **new**

Description: Creates a layout object

Starting with version 0.25, layouts created with the default constructor are always editable. Before that version, they inherited the editable flag from the application.

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new Layout ptr **new** (bool editable, Manager manager)

Description: Creates a layout object attached to a manager

This constructor specifies a manager object which is used to store undo information for example. It also allows one to specify whether the layout is editable. In editable mode, some optimizations are disabled and the layout can be manipulated through a variety of methods.

This method was introduced in version 0.22.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new Layout ptr **new** (bool editable)

Description: Creates a layout object

This constructor specifies whether the layout is editable. In editable mode, some optimizations are disabled and the layout can be manipulated through a variety of methods.

This method was introduced in version 0.22.

Python specific notes:
This method is the default initializer of the object.

pcell_declaration

(1) Signature: *[const]* const PCellDeclaration ptr **pcell_declaration** (string name)

Description: Gets a reference to the PCell declaration for the PCell with the given name

Returns a reference to the local PCell declaration with the given name. If the name is not a valid PCell name, this method returns nil.

Usually this method is used on library layouts that define PCells. Note that this method cannot be used on the layouts using the PCell from a library.

This method has been introduced in version 0.22.

(2) Signature: *[const]* const PCellDeclaration ptr **pcell_declaration** (unsigned int pcell_id)

Description: Gets a reference to the PCell declaration for the PCell with the given PCell ID.

Returns a reference to the local PCell declaration with the given PCell id. If the parameter is not a valid PCell ID, this method returns nil. The PCell ID is the number returned by register_pcell for example.

Usually this method is used on library layouts that define PCells. Note that this method cannot be used on the layouts using the PCell from a library.

This method has been introduced in version 0.22.

pcell_id

Signature: *[const]* unsigned int **pcell_id** (string name)

Description: Gets the ID of the PCell with the given name

This method is equivalent to 'pcell_declaration(name).id'.

This method has been introduced in version 0.22.

pcell_ids

Signature: *[const]* unsigned int[] **pcell_ids**

Description: Gets the IDs of the PCells registered in the layout

Returns an array of PCell IDs.

This method has been introduced in version 0.24.

pcell_names

Signature: *[const]* string[] **pcell_names**

Description: Gets the names of the PCells registered in the layout

Returns an array of PCell names.

This method has been introduced in version 0.24.

prop_id

Signature: *[const]* unsigned long **prop_id**

Description: Gets the properties ID associated with the layout

This method has been introduced in version 0.24.

Python specific notes:
The object exposes a readable attribute 'prop_id'. This is the getter.

prop_id=

Signature: void **prop_id=** (unsigned long id)

Description: Sets the properties ID associated with the layout

This method is provided, if a properties ID has been derived already. Usually it's more convenient to use delete_property, set_property or property.

This method has been introduced in version 0.24.

Python specific notes:
The object exposes a writable attribute 'prop_id'. This is the setter.

properties

Signature: *[const]* variant[] **properties** (unsigned long properties_id)

Description: Gets the properties set for a given properties ID

properties_id:	The properties ID to get the properties for
Returns:	The array of variants (see properties_id)

Basically performs the backward conversion of the 'properties_id' method. Given a properties ID, returns the properties set as an array of pairs of variants. In this array, each key and the value

are stored as pairs (arrays with two elements). If the properties ID is not valid, an empty array is returned.

properties_id

Signature: unsigned long **properties_id** (variant[] properties)

Description: Gets the properties ID for a given properties set

properties:	The array of pairs of variants (both elements can be integer, double or string)
Returns:	The unique properties ID for that set

Before a set of properties can be attached to a shape, it must be converted into an ID that is unique for that set. The properties set must be given as a list of pairs of variants, each pair describing a name and a value. The name acts as the key for the property and does not need to be a string (it can be an integer or double value as well). The backward conversion can be performed with the 'properties' method.

property

Signature: variant **property** (variant key)

Description: Gets the user property with the given key

This method is a convenience method that gets the property with the given key. If no property with that key exists, it will return nil. Using that method is more convenient than using the properties ID to retrieve the property value. This method has been introduced in version 0.24.

prune_cell

Signature: void **prune_cell** (unsigned int cell_index, int levels)

Description: Deletes a cell plus subcells not used otherwise

cell_index:	The index of the cell to delete
levels:	The number of hierarchy levels to consider (-1: all, 0: none, 1: one level etc.)

This deletes a cell and also all sub cells of the cell which are not used otherwise. The number of hierarchy levels to consider can be specified as well. One level of hierarchy means that only the direct children of the cell are deleted with the cell itself. All instances of this cell are deleted as well.

This method has been introduced in version 0.20.

prune_subcells

Signature: void **prune_subcells** (unsigned int cell_index, int levels)

Description: Deletes all sub cells of the cell which are not used otherwise down to the specified level of hierarchy

cell_index:	The root cell from which to delete a sub cells
levels:	The number of hierarchy levels to consider (-1: all, 0: none, 1: one level etc.)

This deletes all sub cells of the cell which are not used otherwise. All instances of the deleted cells are deleted as well. It is possible to specify how many levels of hierarchy below the given root cell are considered.

This method has been introduced in version 0.20.

read

(1) Signature: LayerMap **read** (string filename)

Description: Load the layout from the given file

filename:	The name of the file to load.
Returns:	A layer map that contains the mapping used by the reader including the layers that have been created.

The format of the file is determined automatically and automatic unzipping is provided. No particular options can be specified.

This method has been added in version 0.18.

(2) Signature: LayerMap **read** (string filename, const LoadLayoutOptions options)

Description: Load the layout from the given file with options

filename:	The name of the file to load.
options:	The options object specifying further options for the reader.
Returns:	A layer map that contains the mapping used by the reader including the layers that have been created.

The format of the file is determined automatically and automatic unzipping is provided. In this version, some reader options can be specified.

This method has been added in version 0.18.

refresh

Signature: void **refresh**

Description: Calls Cell#refresh on all cells inside this layout

This method is useful to recompute all PCells from a layout. Note that this does not update PCells which are linked from a library. To recompute PCells from a library, you need to use Library#refresh on the library object from which the PCells are imported.

This method has been introduced in version 0.27.9.

register_pcell

Signature: unsigned int **register_pcell** (string name, PCellDeclaration ptr declaration)

Description: Registers a PCell declaration under the given name

Registers a local PCell in the current layout. If a declaration with that name already exists, it is replaced with the new declaration.

This method has been introduced in version 0.22.

remove_meta_info

Signature: void **remove_meta_info** (string name)

Description: Removes meta information from the layout

See LayoutMetaInfo for details about layouts and meta information. This method has been introduced in version 0.25.

rename_cell

Signature: void **rename_cell** (unsigned int index, string name)

Description: Renames the cell with given index

The cell with the given index is renamed to the given name. NOTE: it is not ensured that the name is unique. This method allows assigning identical names to different cells which usually breaks things. Consider using unique_cell_name to generate truely unique names.

scale_and_snap

(1) Signature: void **scale_and_snap** (Cell cell, int grid, int mult, int div)

Description: Scales and snaps the layout below a given cell by the given rational factor and snaps to the given grid

This method is useful to scale a layout by a non-integer factor. The scale factor is given by the rational number mult / div. After scaling, the layout will be snapped to the given grid.

Snapping happens 'as-if-flat' - that is, touching edges will stay touching, regardless of their hierarchy path. To achieve this, this method usually needs to produce cell variants.

This method has been introduced in version 0.26.1.

(2) Signature: void **scale_and_snap** (unsigned int cell_index, int grid, int mult, int div)

Description: Scales and snaps the layout below a given cell by the given rational factor and snaps to the given grid

Like the other version of scale_and_snap, but taking a cell index for the argument.

This method has been introduced in version 0.26.1.

set_info

Signature: void **set_info** (unsigned int index, const LayerInfo props)

Description: Sets the info structure for a specified layer

set_property

Signature: void **set_property** (variant key, variant value)

Description: Sets the user property with the given key to the given value

This method is a convenience method that sets the property with the given key to the given value. If no property with that key exists, it will create one. Using that method is more convenient than creating a new property set with a new ID and assigning that properties ID. This method may change the properties ID. Note: GDS only supports integer keys. OASIS supports numeric and string keys. This method has been introduced in version 0.24.

start_changes

Signature: void **start_changes**

Description: Signals the start of an operation bringing the layout into invalid state

This method should be called whenever the layout is about to be brought into an invalid state. After calling this method, under_construction? returns true which tells foreign code (i.e. the asynchronous painter or the cell tree view) not to use this layout object.

This state is cancelled by the end_changes method. The start_changes method can be called multiple times and must be cancelled the same number of times.

This method can be used to speed up certain operations. For example iterating over the layout with a RecursiveShapeIterator while modifying other layers of the layout can be very inefficient, because inside the loop the layout's state is invalidate and updated frequently. Putting a update and start_changes sequence before the loop (use both methods in that order!) and a end_changes call after the loop can improve the performance dramatically.

In addition, it can be necessary to prevent redraw operations in certain cases by using start_changes .. end_changes, in particular when it is possible to put a layout object into an invalid state temporarily.

While the layout is under construction update can be called to update the internal state explicitly if required. This for example might be necessary to update the cell bounding boxes or to redo the sorting for region queries.

swap_layers

Signature: void **swap_layers** (unsigned int a, unsigned int b)

Description: Swap two layers

a: The first of the layers to swap.

b: The second of the layers to swap.

Swaps the shapes of both layers.

This method was introduced in version 0.19.

technology

Signature: *[const]* const Technology ptr **technology**

Description: Gets the Technology object of the technology this layout is associated with or nil if the layout is not associated with a technology

This method has been introduced in version 0.27. Before that, the technology has been kept in the 'technology' meta data element.

technology_name

Signature: *[const]* string **technology_name**

Description: Gets the name of the technology this layout is associated with

This method has been introduced in version 0.27. Before that, the technology has been kept in the 'technology' meta data element.

Python specific notes:
The object exposes a readable attribute 'technology_name'. This is the getter.

technology_name=

Signature: void **technology_name=** (string name)

Description: Sets the name of the technology this layout is associated with

Changing the technology name will re-assess all library references because libraries can be technology specified. Cell layouts may be substituted during this re-assessment.

This method has been introduced in version 0.27.

Python specific notes:
The object exposes a writable attribute 'technology_name'. This is the setter.

top_cell

Signature: Cell ptr **top_cell**

Description: Returns the top cell object

Returns: The Cell object of the top cell

If the layout has a single top cell, this method returns the top cell's Cell object. If the layout does not have a top cell, this method returns "nil". If the layout has multiple top cells, this method raises an error.

This method has been introduced in version 0.23.

top_cells

Signature: Cell ptr[] **top_cells**

Description: Returns the top cell objects

Returns: The Cell objects of the top cells

This method returns and array of Cell objects representing the top cells of the layout. This array can be empty, if the layout does not have a top cell (i.e. no cell at all).

This method has been introduced in version 0.23.

transform

(1) Signature: void **transform** (const Trans trans)

Description: Transforms the layout with the given transformation

This method has been introduced in version 0.23.

(2) Signature: void **transform** (const ICplxTrans trans)

Description: Transforms the layout with the given complex integer transformation

This method has been introduced in version 0.23.

(3) Signature: void **transform** (const DTrans trans)

Description: Transforms the layout with the given transformation, which is in micrometer units

This variant will internally translate the transformation's displacement into database units. Apart from that, it behaves identical to the version with a Trans argument.

This variant has been introduced in version 0.25.

(4) Signature: void **transform** (const DCplxTrans trans)

Description: Transforms the layout with the given complex integer transformation, which is in micrometer units

This variant will internally translate the transformation's displacement into database units. Apart from that, it behaves identical to the version with a ICplxTrans argument.

This method has been introduced in version 0.23.

under_construction?

Signature: *[const]* bool **under_construction?**

Description: Returns true if the layout object is under construction

A layout object is either under construction if a transaction is ongoing or the layout is brought into invalid state by "start_changes".

unique_cell_name

Signature: *[const]* string **unique_cell_name** (string name)

Description: Creates a new unique cell name from the given name

Returns: A unique name derived from the argument

If a cell with the given name exists, a suffix will be added to make the name unique. Otherwise, the argument will be returned unchanged.

The returned name can be used to rename cells without risk of creating name clashes.

This method has been introduced in version 0.28.

update

Signature: void **update**

Description: Updates the internals of the layout

This method updates the internal state of the layout. Usually this is done automatically This method is provided to ensure this explicitly. This can be useful while using start_changes and end_changes to wrap a performance-critical operation. See start_changes for more details.

write

(1) Signature: void **write** (string filename, bool gzip, const SaveLayoutOptions options)

Description: Writes the layout to a stream file

filename: The file to which to write the layout

gzip: Ignored

options: The option set to use for writing. See SaveLayoutOptions for details

Use of this method is deprecated

Starting with version 0.23, this variant is deprecated since the more convenient variant with two parameters automatically determines the compression mode from the file name. The gzip parameter is ignored staring with version 0.23.

(2) Signature: void **write** (string filename, const SaveLayoutOptions options)

Description: Writes the layout to a stream file

filename: The file to which to write the layout

options: The option set to use for writing. See SaveLayoutOptions for details

This version automatically determines the compression mode from the file name. The file is written with zlib compression if the suffix is ".gz" or ".gzip".

This variant has been introduced in version 0.23.

(3) Signature: void **write** (string filename)

Description: Writes the layout to a stream file

filename: The file to which to write the layout

4.53. API reference - Class SaveLayoutOptions

Notation used in Ruby API documentation

Module: db

Description: Options for saving layouts

This class describes the various options for saving a layout to a stream file (GDS2, OASIS and others). There are: layers to be saved, cell or cells to be saved, scale factor, format, database unit and format specific options.

Usually the default constructor provides a suitable object. Please note, that the format written is "GDS2" by default. Either explicitly set a format using format= or derive the format from the file name using set_format_from_filename.

The layers are specified by either selecting all layers or by defining layer by layer using the add_layer method. select_all_layers will explicitly select all layers for saving, deselect_all_layers will explicitly clear the list of layers.

Cells are selected in a similar fashion: by default, all cells are selected. Using add_cell, specific cells can be selected for saving. All these cells plus their hierarchy will then be written to the stream file.

Public constructors

new SaveLayoutOptions ptr	**new**		Default constructor

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**add_cell**	(unsigned int cell_index)	Add a cell (plus hierarchy) to be saved
	void	**add_layer**	(unsigned int layer_index, const LayerInfo properties)	Add a layer to be saved
	void	**add_this_cell**	(unsigned int cell_index)	Adds a cell to be saved
	void	**assign**	(const SaveLayoutOptions other)	Assigns another object to self
	void	**cif_blank_separator=**	(bool flag)	Sets a flag indicating whether blanks shall be used as x/y separator characters

[const]	bool	**cif_blank_separator?**		Gets a flag indicating whether blanks shall be used as x/y separator characters
	void	**cif_dummy_calls=**	(bool flag)	Sets a flag indicating whether dummy calls shall be written
[const]	bool	**cif_dummy_calls?**		Gets a flag indicating whether dummy calls shall be written
	void	**clear_cells**		Clears all cells to be saved
[const]	double	**dbu**		Get the explicit database unit if one is set
	void	**dbu=**	(double dbu)	Set the database unit to be used in the stream file
	void	**deselect_all_layers**		Unselect all layers: no layer will be saved
[const]	new SaveLayoutOptions ptr	**dup**		Creates a copy of self
[const]	int	**dxf_polygon_mode**		Specifies how to write polygons.
	void	**dxf_polygon_mode=**	(int mode)	Specifies how to write polygons.
[const]	string	**format**		Gets the format name
	void	**format=**	(string format)	Select a format
[const]	string	**gds2_libname**		Get the library name
	void	**gds2_libname=**	(string libname)	Set the library name
[const]	unsigned int	**gds2_max_cellname_length**		Get the maximum length of cell names
	void	**gds2_max_cellname_length=**	(unsigned int length)	Maximum length of cell names
[const]	unsigned int	**gds2_max_vertex_count**		Gets the maximum number of vertices for polygons to write
	void	**gds2_max_vertex_count=**	(unsigned int count)	Sets the maximum number of vertices for polygons to write
	void	**gds2_multi_xy_records=**	(bool flag)	Uses multiple XY records in BOUNDARY elements for unlimited large polygons
[const]	bool	**gds2_multi_xy_records?**		Gets the property enabling multiple XY records for BOUNDARY elements
	void	**gds2_no_zero_length_paths=**	(bool flag)	Eliminates zero-length paths if true
[const]	bool	**gds2_no_zero_length_paths**		Gets a value indicating whether zero-length paths are eliminated
	void	**gds2_resolve_skew_arrays=**	(bool flag)	Resolves skew arrays into single instances

[const]	bool	**gds2_resolve_skew_arrays?**		Gets a value indicating whether to resolve skew arrays into single instances
[const]	double	**gds2_user_units**		Get the user units
	void	**gds2_user_units=**	(double uu)	Set the users units to write into the GDS file
	void	**gds2_write_cell_properties=**	(bool flag)	Enables writing of cell properties if set to true
[const]	bool	**gds2_write_cell_properties?**		Gets a value indicating whether cell properties are written
	void	**gds2_write_file_properties=**	(bool flag)	Enables writing of file properties if set to true
[const]	bool	**gds2_write_file_properties?**		Gets a value indicating whether layout properties are written
	void	**gds2_write_timestamps=**	(bool flag)	Writes the current time into the GDS2 timestamps if set to true
[const]	bool	**gds2_write_timestamps?**		Gets a value indicating whether the current time is written into the GDS2 timestamp fields
	void	**keep_instances=**	(bool flag)	Enables or disables instances for dropped cells
[const]	bool	**keep_instances?**		Gets a flag indicating whether instances will be kept even if the target cell is dropped
[const]	double	**mag_lambda**		Gets the lambda value
	void	**mag_lambda=**	(double lambda)	Specifies the lambda value to used for writing
[const]	string	**mag_tech**		Gets the technology string used for writing
	void	**mag_tech=**	(string tech)	Specifies the technology string used for writing
	void	**mag_write_timestamp=**	(bool f)	Specifies whether to write a timestamp
[const]	bool	**mag_write_timestamp?**		Gets a value indicating whether to write a timestamp
	void	**no_empty_cells=**	(bool flag)	Don't write empty cells if this flag is set
[const]	bool	**no_empty_cells?**		Returns a flag indicating whether empty cells are not written.
[const]	int	**oasis_compression_level**		Get the OASIS compression level
	void	**oasis_compression_level=**	(int level)	Set the OASIS compression level
	void	**oasis_permissive=**	(bool flag)	Sets OASIS permissive mode
[const]	bool	**oasis_permissive?**		Gets the OASIS permissive mode
	void	**oasis_recompress=**	(bool flag)	Sets OASIS recompression mode

[const]	bool	**oasis_recompress?**		Gets the OASIS recompression mode
	void	**oasis_strict_mode=**	(bool flag)	Sets a value indicating whether to write strict-mode OASIS files
[const]	bool	**oasis_strict_mode?**		Gets a value indicating whether to write strict-mode OASIS files
[const]	string	**oasis_substitution_char**		Gets the substitution character
	void	**oasis_substitution_char=**	(string char)	Sets the substitution character for a-strings and n-strings
	void	**oasis_write_cblocks=**	(bool flag)	Sets a value indicating whether to write compressed CBLOCKS per cell
[const]	bool	**oasis_write_cblocks?**		Gets a value indicating whether to write compressed CBLOCKS per cell
	void	**oasis_write_cell_bounding_boxes=**	(bool flag)	Sets a value indicating whether cell bounding boxes are written
[const]	bool	**oasis_write_cell_bounding_b**		Gets a value indicating whether cell bounding boxes are written
	void	**oasis_write_std_properties=**	(bool flag)	Sets a value indicating whether standard properties will be written
[const]	bool	**oasis_write_std_properties?**		Gets a value indicating whether standard properties will be written
[const]	double	**scale_factor**		Gets the scaling factor currently set
	void	**scale_factor=**	(double scale_factor)	Set the scaling factor for the saving
	void	**select_all_cells**		Select all cells to save
	void	**select_all_layers**		Select all layers to be saved
	void	**select_cell**	(unsigned int cell_index)	Selects a cell to be saved (plus hierarchy below)
	void	**select_this_cell**	(unsigned int cell_index)	Selects a cell to be saved
	bool	**set_format_from_filename**	(string filename)	Select a format from the given file name
	void	**write_context_info=**	(bool flag)	Enables or disables context information
[const]	bool	**write_context_info?**		Gets a flag indicating whether context information will be stored

Deprecated methods (protected, public, static, non-static and constructors)

[const]	bool	**cif_blank_separator**	Use of this method is deprecated. Use cif_blank_separator? instead
[const]	bool	**cif_dummy_calls**	Use of this method is deprecated. Use cif_dummy_calls? instead
	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

add_cell

Signature: void **add_cell** (unsigned int cell_index)

Description: Add a cell (plus hierarchy) to be saved

The index of the cell must be a valid index in the context of the layout that will be saved. This method clears the 'select all cells' flag.

This method also implicitly adds the children of that cell. A method that does not add the children in add_this_cell.

add_layer

Signature: void **add_layer** (unsigned int layer_index, const LayerInfo properties)

Description: Add a layer to be saved

Adds the layer with the given index to the layer list that will be written. If all layers have been selected previously, all layers will be unselected first and only the new layer remains.

The 'properties' argument can be used to assign different layer properties than the ones present in the layout. Pass a default LayerInfo object to this argument to use the properties from the layout object. Construct a valid LayerInfo object with explicit layer, datatype and possibly a name to override the properties stored in the layout.

add_this_cell

Signature: void **add_this_cell** (unsigned int cell_index)

Description: Adds a cell to be saved

The index of the cell must be a valid index in the context of the layout that will be saved. This method clears the 'select all cells' flag. Unlike add_cell, this method does not implicitly add all children of that cell.

This method has been added in version 0.23.

assign

Signature: void **assign** (const SaveLayoutOptions other)

Description: Assigns another object to self

cif_blank_separator

Signature: *[const]* bool **cif_blank_separator**

Description: Gets a flag indicating whether blanks shall be used as x/y separator characters

Use of this method is deprecated. Use cif_blank_separator? instead

See cif_blank_separator= method for a description of that property. This property has been added in version 0.23.10.

The predicate version (cif_blank_separator?) has been added in version 0.25.1.

Python specific notes:
The object exposes a readable attribute 'cif_blank_separator'. This is the getter.
This method is available as 'cif_blank_separator_' in Python to distiguish it from the property with the same name.

cif_blank_separator=

Signature: void **cif_blank_separator=** (bool flag)

Description: Sets a flag indicating whether blanks shall be used as x/y separator characters

If this property is set to true, the x and y coordinates are separated with blank characters rather than comma characters. This property has been added in version 0.23.10.

Python specific notes:
The object exposes a writable attribute 'cif_blank_separator'. This is the setter.

cif_blank_separator?

Signature: *[const]* bool **cif_blank_separator?**

Description: Gets a flag indicating whether blanks shall be used as x/y separator characters

See cif_blank_separator= method for a description of that property. This property has been added in version 0.23.10.

The predicate version (cif_blank_separator?) has been added in version 0.25.1.

Python specific notes:
The object exposes a readable attribute 'cif_blank_separator'. This is the getter.
This method is available as 'cif_blank_separator_' in Python to distiguish it from the property with the same name.

cif_dummy_calls

Signature: *[const]* bool **cif_dummy_calls**

Description: Gets a flag indicating whether dummy calls shall be written

Use of this method is deprecated. Use cif_dummy_calls? instead

See cif_dummy_calls= method for a description of that property. This property has been added in version 0.23.10.

The predicate version (cif_blank_separator?) has been added in version 0.25.1.

Python specific notes:
The object exposes a readable attribute 'cif_dummy_calls'. This is the getter.
This method is available as 'cif_dummy_calls_' in Python to distiguish it from the property with the same name.

cif_dummy_calls=

Signature: void **cif_dummy_calls=** (bool flag)

Description: Sets a flag indicating whether dummy calls shall be written

If this property is set to true, dummy calls will be written in the top level entity of the CIF file calling every top cell. This option is useful for enhanced compatibility with other tools.

This property has been added in version 0.23.10.

Python specific notes:
The object exposes a writable attribute 'cif_dummy_calls'. This is the setter.

cif_dummy_calls?

Signature: *[const]* bool **cif_dummy_calls?**

Description: Gets a flag indicating whether dummy calls shall be written

See cif_dummy_calls= method for a description of that property. This property has been added in version 0.23.10.

The predicate version (cif_blank_separator?) has been added in version 0.25.1.

Python specific notes:
The object exposes a readable attribute 'cif_dummy_calls'. This is the getter.
This method is available as 'cif_dummy_calls_' in Python to distiguish it from the property with the same name.

clear_cells

Signature: void **clear_cells**

Description: Clears all cells to be saved

This method can be used to ensure that no cell is selected before add_cell is called to specify a cell. This method clears the 'select all cells' flag.

This method has been added in version 0.22.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

dbu

Signature: *[const]* double **dbu**

Description: Get the explicit database unit if one is set

See dbu= for a description of that attribute.

Python specific notes:
The object exposes a readable attribute 'dbu'. This is the getter.

dbu=

Signature: void **dbu=** (double dbu)

Description: Set the database unit to be used in the stream file

By default, the database unit of the layout is used. This method allows one to explicitly use a different database unit. A scale factor is introduced automatically which scales all layout objects accordingly so their physical dimensions remain the same. When scaling to a larger database unit or one that is not an integer fraction of the original one, rounding errors may occur and the layout may become slightly distorted.

Python specific notes:
The object exposes a writable attribute 'dbu'. This is the setter.

deselect_all_layers

Signature: void **deselect_all_layers**

Description: Unselect all layers: no layer will be saved

This method will clear all layers selected with add_layer so far and clear the 'select all layers' flag. Using this method is the only way to save a layout without any layers.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new SaveLayoutOptions ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

dxf_polygon_mode

Signature: *[const]* int **dxf_polygon_mode**

Description: Specifies how to write polygons.

See dxf_polygon_mode= for a description of this property.

This property has been added in version 0.21.3.

Python specific notes:
The object exposes a readable attribute 'dxf_polygon_mode'. This is the getter.

dxf_polygon_mode=

Signature: void **dxf_polygon_mode=** (int mode)

Description: Specifies how to write polygons.

The mode is 0 (write POLYLINE entities), 1 (write LWPOLYLINE entities), 2 (decompose into SOLID entities), 3 (write HATCH entities), or 4 (write LINE entities).

This property has been added in version 0.21.3. '4', in version 0.25.6.

Python specific notes:
The object exposes a writable attribute 'dxf_polygon_mode'. This is the setter.

format

Signature: *[const]* string **format**

Description: Gets the format name

See format= for a description of that method.

Python specific notes:
The object exposes a readable attribute 'format'. This is the getter.

format=

Signature: void **format=** (string format)

Description: Select a format

The format string can be either "GDS2", "OASIS", "CIF" or "DXF". Other formats may be available if a suitable plugin is installed.

Python specific notes:
The object exposes a writable attribute 'format'. This is the setter.

gds2_libname

Signature: *[const]* string **gds2_libname**

Description: Get the library name

See gds2_libname= method for a description of the library name. This property has been added in version 0.18.

Python specific notes:
The object exposes a readable attribute 'gds2_libname'. This is the getter.

gds2_libname=

Signature: void **gds2_libname=** (string libname)

Description: Set the library name

The library name is the string written into the LIBNAME records of the GDS file. The library name should not be an empty string and is subject to certain limitations in the character choice.

This property has been added in version 0.18.

Python specific notes:
The object exposes a writable attribute 'gds2_libname'. This is the setter.

gds2_max_cellname_length

Signature: *[const]* unsigned int **gds2_max_cellname_length**

Description: Get the maximum length of cell names

See gds2_max_cellname_length= method for a description of the maximum cell name length. This property has been added in version 0.18.

Python specific notes:
The object exposes a readable attribute 'gds2_max_cellname_length'. This is the getter.

gds2_max_cellname_length=

Signature: void **gds2_max_cellname_length=** (unsigned int length)

Description: Maximum length of cell names

This property describes the maximum number of characters for cell names. Longer cell names will be shortened.

This property has been added in version 0.18.

Python specific notes:
The object exposes a writable attribute 'gds2_max_cellname_length'. This is the setter.

gds2_max_vertex_count

Signature: *[const]* unsigned int **gds2_max_vertex_count**

Description: Gets the maximum number of vertices for polygons to write

See gds2_max_vertex_count= method for a description of the maximum vertex count. This property has been added in version 0.18.

Python specific notes:
The object exposes a readable attribute 'gds2_max_vertex_count'. This is the getter.

gds2_max_vertex_count=

Signature: void **gds2_max_vertex_count=** (unsigned int count)

Description: Sets the maximum number of vertices for polygons to write

This property describes the maximum number of point for polygons in GDS2 files. Polygons with more points will be split. The minimum value for this property is 4. The maximum allowed value is about 4000 or 8000, depending on the GDS2 interpretation. If gds2_multi_xy_records is true, this property is not used. Instead, the number of points is unlimited.

This property has been added in version 0.18.

Python specific notes:
The object exposes a writable attribute 'gds2_max_vertex_count'. This is the setter.

gds2_multi_xy_records=

Signature: void **gds2_multi_xy_records=** (bool flag)

Description: Uses multiple XY records in BOUNDARY elements for unlimited large polygons

Setting this property to true allows producing polygons with an unlimited number of points at the cost of incompatible formats. Setting it to true disables the gds2_max_vertex_count setting.

This property has been added in version 0.18.

Python specific notes:
The object exposes a writable attribute 'gds2_multi_xy_records'. This is the setter.

gds2_multi_xy_records?

Signature: *[const]* bool **gds2_multi_xy_records?**

Description: Gets the property enabling multiple XY records for BOUNDARY elements

See gds2_multi_xy_records= method for a description of this property. This property has been added in version 0.18.

Python specific notes:
The object exposes a readable attribute 'gds2_multi_xy_records'. This is the getter.

gds2_no_zero_length_paths

Signature: *[const]* bool **gds2_no_zero_length_paths**

Description: Gets a value indicating whether zero-length paths are eliminated

Use of this method is deprecated. Use gds2_no_zero_length_paths? instead

This property has been added in version 0.23.

Python specific notes:
The object exposes a readable attribute 'gds2_no_zero_length_paths'. This is the getter.
This method is available as 'gds2_no_zero_length_paths_' in Python to distiguish it from the property with the same name.

gds2_no_zero_length_paths=

Signature: void **gds2_no_zero_length_paths=** (bool flag)

Description: Eliminates zero-length paths if true

If this property is set to true, paths with zero length will be converted to BOUNDARY objects.

This property has been added in version 0.23.

Python specific notes:
The object exposes a writable attribute 'gds2_no_zero_length_paths'. This is the setter.

gds2_no_zero_length_paths?

Signature: *[const]* bool **gds2_no_zero_length_paths?**

Description: Gets a value indicating whether zero-length paths are eliminated

This property has been added in version 0.23.

Python specific notes:
The object exposes a readable attribute 'gds2_no_zero_length_paths'. This is the getter.
This method is available as 'gds2_no_zero_length_paths_' in Python to distiguish it from the property with the same name.

gds2_resolve_skew_arrays=

Signature: void **gds2_resolve_skew_arrays=** (bool flag)

Description: Resolves skew arrays into single instances

Setting this property to true will make skew (non-orthogonal) arrays being resolved into single instances. Skew arrays happen if either the row or column vector isn't parallel to x or y axis. Such arrays can cause problems with some legacy software and can be disabled with this option.

This property has been added in version 0.27.1.

Python specific notes:
The object exposes a writable attribute 'gds2_resolve_skew_arrays'. This is the setter.

gds2_resolve_skew_arrays?

Signature: *[const]* bool **gds2_resolve_skew_arrays?**

Description: Gets a value indicating whether to resolve skew arrays into single instances

See gds2_resolve_skew_arrays= method for a description of this property. This property has been added in version 0.27.1.

Python specific notes:
The object exposes a readable attribute 'gds2_resolve_skew_arrays'. This is the getter.

gds2_user_units

Signature: *[const]* double **gds2_user_units**

Description: Get the user units

See gds2_user_units= method for a description of the user units. This property has been added in version 0.18.

Python specific notes:
The object exposes a readable attribute 'gds2_user_units'. This is the getter.

gds2_user_units=

Signature: void **gds2_user_units=** (double uu)

Description: Set the users units to write into the GDS file

The user units of a GDS file are rarely used and usually are set to 1 (micron). The intention of the user units is to specify the display units. KLayout ignores the user unit and uses microns as the display unit. The user unit must be larger than zero.

This property has been added in version 0.18.

Python specific notes:
The object exposes a writable attribute 'gds2_user_units'. This is the setter.

gds2_write_cell_properties

Signature: *[const]* bool **gds2_write_cell_properties**

Description: Gets a value indicating whether cell properties are written

Use of this method is deprecated. Use gds2_write_cell_properties? instead

This property has been added in version 0.23.

Python specific notes:
The object exposes a readable attribute 'gds2_write_cell_properties'. This is the getter.
This method is available as 'gds2_write_cell_properties_' in Python to distiguish it from the property with the same name.

gds2_write_cell_properties=

Signature: void **gds2_write_cell_properties=** (bool flag)

Description: Enables writing of cell properties if set to true

If this property is set to true, cell properties will be written as PROPATTR/PROPVALUE records immediately following the BGNSTR records. This is a non-standard extension and is therefore disabled by default.

This property has been added in version 0.23.

Python specific notes:
The object exposes a writable attribute 'gds2_write_cell_properties'. This is the setter.

gds2_write_cell_properties?

Signature: *[const]* bool **gds2_write_cell_properties?**

Description: Gets a value indicating whether cell properties are written

This property has been added in version 0.23.

Python specific notes:
The object exposes a readable attribute 'gds2_write_cell_properties'. This is the getter.

This method is available as 'gds2_write_cell_properties_' in Python to distiguish it from the property with the same name.

gds2_write_file_properties

Signature: *[const]* bool **gds2_write_file_properties**

Description: Gets a value indicating whether layout properties are written

Use of this method is deprecated. Use gds2_write_file_properties? instead

This property has been added in version 0.24.

Python specific notes:
The object exposes a readable attribute 'gds2_write_file_properties'. This is the getter.
This method is available as 'gds2_write_file_properties_' in Python to distiguish it from the property with the same name.

gds2_write_file_properties=

Signature: void **gds2_write_file_properties=** (bool flag)

Description: Enables writing of file properties if set to true

If this property is set to true, layout properties will be written as PROPATTR/PROPVALUE records immediately following the BGNLIB records. This is a non-standard extension and is therefore disabled by default.

This property has been added in version 0.24.

Python specific notes:
The object exposes a writable attribute 'gds2_write_file_properties'. This is the setter.

gds2_write_file_properties?

Signature: *[const]* bool **gds2_write_file_properties?**

Description: Gets a value indicating whether layout properties are written

This property has been added in version 0.24.

Python specific notes:
The object exposes a readable attribute 'gds2_write_file_properties'. This is the getter.
This method is available as 'gds2_write_file_properties_' in Python to distiguish it from the property with the same name.

gds2_write_timestamps=

Signature: void **gds2_write_timestamps=** (bool flag)

Description: Writes the current time into the GDS2 timestamps if set to true

If this property is set to false, the time fields will all be zero. This somewhat simplifies compare and diff applications.

This property has been added in version 0.21.16.

Python specific notes:
The object exposes a writable attribute 'gds2_write_timestamps'. This is the setter.

gds2_write_timestamps?

Signature: *[const]* bool **gds2_write_timestamps?**

Description: Gets a value indicating whether the current time is written into the GDS2 timestamp fields

This property has been added in version 0.21.16.

Python specific notes:
The object exposes a readable attribute 'gds2_write_timestamps'. This is the getter.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

keep_instances=

Signature: void **keep_instances=** (bool flag)

Description: Enables or disables instances for dropped cells

If this flag is set to true, instances for cells will be written, even if the cell is dropped. That may happen, if cells are selected with select_this_cell or add_this_cell or no_empty_cells is used. Even if cells called by such cells are not selected, instances will be written for that cell if "keep_instances" is true. That feature is supported by the GDS format currently and results in "ghost cells" which have instances but no cell definition.

The default value is false (instances of dropped cells are not written).

This method was introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'keep_instances'. This is the setter.

keep_instances?

Signature: *[const]* bool **keep_instances?**

Description: Gets a flag indicating whether instances will be kept even if the target cell is dropped

See keep_instances= for details about this flag.

This method was introduced in version 0.23.

Python specific notes:
The object exposes a readable attribute 'keep_instances'. This is the getter.

mag_lambda

Signature: *[const]* double **mag_lambda**

Description: Gets the lambda value

See mag_lambda= method for a description of this attribute. This property has been added in version 0.26.2.

Python specific notes:
The object exposes a readable attribute 'mag_lambda'. This is the getter.

mag_lambda=

Signature: void **mag_lambda=** (double lambda)

Description: Specifies the lambda value to used for writing

The lambda value is the basic unit of the layout. The layout is brought to units of this value. If the layout is not on-grid on this unit, snapping will happen. If the value is less or equal to zero, KLayout will use the lambda value stored inside the layout set by a previous read operation of a MAGIC file. The lambda value is stored in the Layout object as the "lambda" metadata attribute.

This property has been added in version 0.26.2.

Python specific notes:
The object exposes a writable attribute 'mag_lambda'. This is the setter.

mag_tech

Signature: *[const]* string **mag_tech**

Description: Gets the technology string used for writing

See mag_tech= method for a description of this attribute. This property has been added in version 0.26.2.

Python specific notes:
The object exposes a readable attribute 'mag_tech'. This is the getter.

mag_tech=

Signature: void **mag_tech=** (string tech)

Description: Specifies the technology string used for writing

If this string is empty, the writer will try to obtain the technology from the "technology" metadata attribute of the layout.

This property has been added in version 0.26.2.

Python specific notes:
The object exposes a writable attribute 'mag_tech'. This is the setter.

mag_write_timestamp=

Signature: void **mag_write_timestamp=** (bool f)

Description: Specifies whether to write a timestamp

If this attribute is set to false, the timestamp written is 0. This is not permitted in the strict sense, but simplifies comparison of Magic files.

This property has been added in version 0.26.2.

Python specific notes:
The object exposes a writable attribute 'mag_write_timestamp'. This is the setter.

mag_write_timestamp?

Signature: *[const]* bool **mag_write_timestamp?**

Description: Gets a value indicating whether to write a timestamp

See write_timestamp= method for a description of this attribute.

This property has been added in version 0.26.2.

Python specific notes:
The object exposes a readable attribute 'mag_write_timestamp'. This is the getter.

new

Signature: *[static]* new SaveLayoutOptions ptr **new**

Description: Default constructor

This will initialize the scale factor to 1.0, the database unit is set to "same as original" and all layers are selected as well as all cells. The default format is GDS2.

Python specific notes:
This method is the default initializer of the object.

no_empty_cells=

Signature: void **no_empty_cells=** (bool flag)

Description: Don't write empty cells if this flag is set

By default, all cells are written (no_empty_cells is false). This applies to empty cells which do not contain shapes for the specified layers as well as cells which are empty because they reference empty cells only.

Python specific notes:
The object exposes a writable attribute 'no_empty_cells'. This is the setter.

no_empty_cells?

Signature: *[const]* bool **no_empty_cells?**

Description: Returns a flag indicating whether empty cells are not written.

Python specific notes:
The object exposes a readable attribute 'no_empty_cells'. This is the getter.

oasis_compression_level

Signature: *[const]* int **oasis_compression_level**

Description: Get the OASIS compression level

See oasis_compression_level= method for a description of the OASIS compression level.

Python specific notes:
The object exposes a readable attribute 'oasis_compression_level'. This is the getter.

oasis_compression_level=

Signature: void **oasis_compression_level=** (int level)

Description: Set the OASIS compression level

The OASIS compression level is an integer number between 0 and 10. 0 basically is no compression, 1 produces shape arrays in a simple fashion. 2 and higher compression levels will use a more elaborate algorithm to find shape arrays which uses 2nd and further neighbor distances. The higher the level, the higher the memory requirements and run times.

Python specific notes:
The object exposes a writable attribute 'oasis_compression_level'. This is the setter.

oasis_permissive=

Signature: void **oasis_permissive=** (bool flag)

Description: Sets OASIS permissive mode

If this flag is true, certain shapes which cannot be written to OASIS are reported as warnings, not as errors. For example, paths with odd width (are rounded) or polygons with less than three points (are skipped).

This method has been introduced in version 0.25.1.

Python specific notes:
The object exposes a writable attribute 'oasis_permissive'. This is the setter.

oasis_permissive?

Signature: *[const]* bool **oasis_permissive?**

Description: Gets the OASIS permissive mode

See oasis_permissive= method for a description of this predicate. This method has been introduced in version 0.25.1.

Python specific notes:
The object exposes a readable attribute 'oasis_permissive'. This is the getter.

oasis_recompress=

Signature: void **oasis_recompress=** (bool flag)

Description: Sets OASIS recompression mode

If this flag is true, shape arrays already existing will be resolved and compression is applied to the individual shapes again. If this flag is false (the default), shape arrays already existing will be written as such.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'oasis_recompress'. This is the setter.

oasis_recompress?

Signature: *[const]* bool **oasis_recompress?**

Description: Gets the OASIS recompression mode

See oasis_recompress= method for a description of this predicate. This method has been introduced in version 0.23.

Python specific notes:
The object exposes a readable attribute 'oasis_recompress'. This is the getter.

oasis_strict_mode=

Signature: void **oasis_strict_mode=** (bool flag)

Description: Sets a value indicating whether to write strict-mode OASIS files

Setting this property clears all format specific options for other formats such as GDS.

Python specific notes:
The object exposes a writable attribute 'oasis_strict_mode'. This is the setter.

oasis_strict_mode?

Signature: *[const]* bool **oasis_strict_mode?**

Description: Gets a value indicating whether to write strict-mode OASIS files

Python specific notes:
The object exposes a readable attribute 'oasis_strict_mode'. This is the getter.

oasis_substitution_char

Signature: *[const]* string **oasis_substitution_char**

Description: Gets the substitution character

See oasis_substitution_char for details. This attribute has been introduced in version 0.23.

Python specific notes:
The object exposes a readable attribute 'oasis_substitution_char'. This is the getter.

oasis_substitution_char=

Signature: void **oasis_substitution_char=** (string char)

Description: Sets the substitution character for a-strings and n-strings

The substitution character is used in place of invalid characters. The value of this attribute is a string which is either empty or a single character. If the string is empty, no substitution is made at the risk of producing invalid OASIS files.

This attribute has been introduce in version 0.23.

Python specific notes:
The object exposes a writable attribute 'oasis_substitution_char'. This is the setter.

oasis_write_cblocks=

Signature: void **oasis_write_cblocks=** (bool flag)

Description: Sets a value indicating whether to write compressed CBLOCKS per cell

Setting this property clears all format specific options for other formats such as GDS.

Python specific notes:
The object exposes a writable attribute 'oasis_write_cblocks'. This is the setter.

oasis_write_cblocks?

Signature: *[const]* bool **oasis_write_cblocks?**

Description: Gets a value indicating whether to write compressed CBLOCKS per cell

Python specific notes:
The object exposes a readable attribute 'oasis_write_cblocks'. This is the getter.

oasis_write_cell_bounding_boxes=

Signature: void **oasis_write_cell_bounding_boxes=** (bool flag)

Description: Sets a value indicating whether cell bounding boxes are written

If this value is set to true, cell bounding boxes are written (S_BOUNDING_BOX). The S_BOUNDING_BOX properties will be attached to the CELLNAME records.

Setting this value to true will also enable writing of other standard properties like S_TOP_CELL (see oasis_write_std_properties=). By default, cell bounding boxes are not written, but standard properties are.

This method has been introduced in version 0.24.3.

Python specific notes:
The object exposes a writable attribute 'oasis_write_cell_bounding_boxes'. This is the setter.

oasis_write_cell_bounding_bo

Signature: *[const]* bool **oasis_write_cell_bounding_boxes?**

Description: Gets a value indicating whether cell bounding boxes are written

	See oasis_write_cell_bounding_boxes= method for a description of this flag. This method has been introduced in version 0.24.3. **Python specific notes:** The object exposes a readable attribute 'oasis_write_cell_bounding_boxes'. This is the getter.
oasis_write_std_properties=	**Signature**: void **oasis_write_std_properties=** (bool flag) **Description**: Sets a value indicating whether standard properties will be written If this value is false, no standard properties are written. If true, S_TOP_CELL and some other global standard properties are written. In addition, oasis_write_cell_bounding_boxes= can be used to write cell bounding boxes using S_BOUNDING_BOX. By default, this flag is true and standard properties are written. Setting this property to false clears the oasis_write_cell_bounding_boxes flag too. This method has been introduced in version 0.24. **Python specific notes:** The object exposes a writable attribute 'oasis_write_std_properties'. This is the setter.
oasis_write_std_properties?	**Signature**: *[const]* bool **oasis_write_std_properties?** **Description**: Gets a value indicating whether standard properties will be written See oasis_write_std_properties= method for a description of this flag. This method has been introduced in version 0.24. **Python specific notes:** The object exposes a readable attribute 'oasis_write_std_properties'. This is the getter.
scale_factor	**Signature**: *[const]* double **scale_factor** **Description**: Gets the scaling factor currently set **Python specific notes:** The object exposes a readable attribute 'scale_factor'. This is the getter.
scale_factor=	**Signature**: void **scale_factor=** (double scale_factor) **Description**: Set the scaling factor for the saving Using a scaling factor will scale all objects accordingly. This scale factor adds to a potential scaling implied by using an explicit database unit. Be aware that rounding effects may occur if fractional scaling factors are used. By default, no scaling is applied. **Python specific notes:** The object exposes a writable attribute 'scale_factor'. This is the setter.
select_all_cells	**Signature**: void **select_all_cells** **Description**: Select all cells to save This method will clear all cells specified with add_cells so far and set the 'select all cells' flag. This is the default.
select_all_layers	**Signature**: void **select_all_layers** **Description**: Select all layers to be saved This method will clear all layers selected with add_layer so far and set the 'select all layers' flag. This is the default.

select_cell

Signature: void **select_cell** (unsigned int cell_index)

Description: Selects a cell to be saved (plus hierarchy below)

This method is basically a convenience method that combines clear_cells and add_cell. This method clears the 'select all cells' flag.

This method has been added in version 0.22.

select_this_cell

Signature: void **select_this_cell** (unsigned int cell_index)

Description: Selects a cell to be saved

This method is basically a convenience method that combines clear_cells and add_this_cell. This method clears the 'select all cells' flag.

This method has been added in version 0.23.

set_format_from_filename

Signature: bool **set_format_from_filename** (string filename)

Description: Select a format from the given file name

This method will set the format according to the file's extension.

This method has been introduced in version 0.22. Beginning with version 0.23, this method always returns true, since the only consumer for the return value, Layout#write, now ignores that parameter and automatically determines the compression mode from the file name.

write_context_info=

Signature: void **write_context_info=** (bool flag)

Description: Enables or disables context information

If this flag is set to false, no context information for PCell or library cell instances is written. Those cells will be converted to plain cells and KLayout will not be able to restore the identity of those cells. Use this option to enforce compatibility with other tools that don't understand the context information of KLayout.

The default value is true (context information is stored). Not all formats support context information, hence that flag has no effect for formats like CIF or DXF.

This method was introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'write_context_info'. This is the setter.

write_context_info?

Signature: *[const]* bool **write_context_info?**

Description: Gets a flag indicating whether context information will be stored

See write_context_info= for details about this flag.

This method was introduced in version 0.23.

Python specific notes:
The object exposes a readable attribute 'write_context_info'. This is the getter.

4.54. API reference - Class LayoutQueryIterator

Notation used in Ruby API documentation

Module: db

Description: Provides the results of the query

This object is used by LayoutQuery#each to deliver the results of a query in an iterative fashion. See LayoutQuery for a detailed description of the query interface.

The LayoutQueryIterator class has been introduced in version 0.25.

Public constructors

new LayoutQueryIterator ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	variant	**cell**		A shortcut for 'get("cell")'
	variant	**cell_index**		A shortcut for 'get("cell_index")'
	variant	**data**		A shortcut for 'get("data")'
	variant	**dtrans**		A shortcut for 'get("dtrans")'
	variant	**get**	(string name)	Gets the query property with the given name
	variant	**initial_cell**		A shortcut for 'get("initial_cell")'
	variant	**initial_cell_index**		A shortcut for 'get("initial_cell_index")'
	variant	**inst**		A shortcut for 'get("inst")'
	variant	**layer_index**		A shortcut for 'get("layer_index")'
[const]	const Layout ptr	**layout**		Gets the layout the query acts on
	variant	**parent_cell**		A shortcut for 'get("parent_cell")'
	variant	**parent_cell_index**		A shortcut for 'get("parent_cell_index")'

	variant	path_dtrans	A shortcut for 'get("path_dtrans")'
	variant	path_trans	A shortcut for 'get("path_trans")'
[const]	const LayoutQuery ptr	query	Gets the query the iterator follows on
	variant	shape	A shortcut for 'get("shape")'
	variant	trans	A shortcut for 'get("trans")'

Deprecated methods (protected, public, static, non-static and constructors)

	void	create	Use of this method is deprecated. Use _create instead
	void	destroy	Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	is_const_object?	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void _**create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void _**destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool _**destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool _**is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void _**manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the

	object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required. Usually it's not required to call this method. It has been introduced in version 0.24.
_unmanage	**Signature**: void **_unmanage** **Description**: Marks the object as no longer owned by the script side. Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.
cell	**Signature**: variant **cell** **Description**: A shortcut for 'get("cell")'
cell_index	**Signature**: variant **cell_index** **Description**: A shortcut for 'get("cell_index")'
create	**Signature**: void **create** **Description**: Ensures the C++ object is created Use of this method is deprecated. Use _create instead Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
data	**Signature**: variant **data** **Description**: A shortcut for 'get("data")'
destroy	**Signature**: void **destroy** **Description**: Explicitly destroys the object Use of this method is deprecated. Use _destroy instead Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
destroyed?	**Signature**: *[const]* bool **destroyed?** **Description**: Returns a value indicating whether the object was already destroyed Use of this method is deprecated. Use _destroyed? instead This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
dtrans	**Signature**: variant **dtrans** **Description**: A shortcut for 'get("dtrans")'

get	**Signature**: variant **get** (string name) **Description**: Gets the query property with the given name The query properties available can be obtained from the query object using LayoutQuery#property_names. Some shortcut methods are available. For example, the data method provides a shortcut for 'get("data")'. If a property with the given name is not available, nil will be returned.
initial_cell	**Signature**: variant **initial_cell** **Description**: A shortcut for 'get("initial_cell")'
initial_cell_index	**Signature**: variant **initial_cell_index** **Description**: A shortcut for 'get("initial_cell_index")'
inst	**Signature**: variant **inst** **Description**: A shortcut for 'get("inst")'
is_const_object?	**Signature**: *[const]* bool **is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.
layer_index	**Signature**: variant **layer_index** **Description**: A shortcut for 'get("layer_index")'
layout	**Signature**: *[const]* const Layout ptr **layout** **Description**: Gets the layout the query acts on
new	**Signature**: *[static]* new LayoutQueryIterator ptr **new** **Description**: Creates a new object of this class **Python specific notes:** This method is the default initializer of the object.
parent_cell	**Signature**: variant **parent_cell** **Description**: A shortcut for 'get("parent_cell")'
parent_cell_index	**Signature**: variant **parent_cell_index** **Description**: A shortcut for 'get("parent_cell_index")'
path_dtrans	**Signature**: variant **path_dtrans** **Description**: A shortcut for 'get("path_dtrans")'
path_trans	**Signature**: variant **path_trans** **Description**: A shortcut for 'get("path_trans")'

query	**Signature**: *[const]* const LayoutQuery ptr **query** **Description**: Gets the query the iterator follows on
shape	**Signature**: variant **shape** **Description**: A shortcut for 'get("shape")'
trans	**Signature**: variant **trans** **Description**: A shortcut for 'get("trans")'

4.55. API reference - Class LayoutQuery

Notation used in Ruby API documentation

Module: db

Description: A layout query

Layout queries are the backbone of the "Search & replace" feature. Layout queries allow retrieval of data from layouts and manipulation of layouts. This object provides script binding for this feature. Layout queries are used by first creating a query object. Depending on the nature of the query, either execute or each can be used to execute the query. execute will run the query and return once the query is finished. execute is useful for running queries that don't return results such as "delete" or "with ... do" queries. each can be used when the results of the query need to be retrieved.

The each method will call a block a of code for every result available. It will provide a LayoutQueryIterator object that allows accessing the results of the query. Depending on the query, different attributes of the iterator object will be available. For example, "select" queries will fill the "data" attribute with an array of values corresponding to the columns of the selection.

Here is some sample code:

```
ly = RBA::CellView::active.layout
q = RBA::LayoutQuery::new("select cell.name, cell.bbox from *")
q.each(ly) do |iter|
  puts "cell name: #{iter.data[0]}, bounding box: #{iter.data[1]}"
end
```

The LayoutQuery class has been introduced in version 0.25.

Public constructors

new LayoutQuery ptr	**new**	(string query)		Creates a new query object from the given query string

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const,iter]	LayoutQueryIterator	**each**	(const Layout ptr layout, ExpressionConte ptr context = nil)	Executes the query and delivered the results iteratively.
	void	**execute**	(Layout layout,	Executes the query

			ExpressionContext ptr context = nil)
[const]	string[]	**property_names**	Gets a list of property names available.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

each

Signature: *[const,iter]* LayoutQueryIterator **each** (const Layout ptr layout, ExpressionContext ptr context = nil)

Description: Executes the query and delivered the results iteratively.

The argument to the block is a LayoutQueryIterator object which can be asked for specific results.

The context argument allows supplying an expression execution context. This context can be used for example to supply variables for the execution. It has been added in version 0.26.

execute

Signature: void **execute** (Layout layout, ExpressionContext ptr context = nil)

Description: Executes the query

This method can be used to execute "active" queries such as "delete" or "with ... do". It is basically equivalent to iterating over the query until it is done.

The context argument allows supplying an expression execution context. This context can be used for example to supply variables for the execution. It has been added in version 0.26.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new LayoutQuery ptr **new** (string query)

Description: Creates a new query object from the given query string

Python specific notes:
This method is the default initializer of the object.

property_names

Signature: *[const]* string[] **property_names**

Description: Gets a list of property names available.

The list of properties available from the query depends on the nature of the query. This method allows detection of the properties available. Within the query, all of these properties can be obtained from the query iterator using LayoutQueryIterator#get.

4.56. API reference - Class Library

Notation used in Ruby API documentation

Module: db

Description: A Library

A library is basically a wrapper around a layout object. The layout object provides cells and potentially PCells that can be imported into other layouts.

The library provides a name which is used to identify the library and a description which is used for identifying the library in a user interface.

After a library is created and the layout is filled, it must be registered using the register method.

This class has been introduced in version 0.22.

Public constructors

new Library ptr	**new**		Creates a new, empty library

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**add_technology**	(string tech)	Additionally associates the library with the given technology.
	void	**assign**	(const Library other)	Assigns another object to self
	void	**clear_technologies**		Clears the list of technologies the library is associated with.
	void	**delete**		Deletes the library
[const]	string	**description**		Returns the libraries' description text
	void	**description=**	(string description)	Sets the libraries' description text
[const]	new Library ptr	**dup**		Creates a copy of self
[const]	bool	**for_technologies**		Returns a value indicating whether the library is associated with any technology.

[const]	unsigned long	**id**		Returns the library's ID
[const]	bool	**is_for_technology**	(string tech)	Returns a value indicating whether the library is associated with the given technology.
	Layout	**layout**		The layout object where the cells reside that this library defines
[const]	Layout	**layout_const**		The layout object where the cells reside that this library defines (const version)
[const]	string	**name**		Returns the libraries' name
	void	**refresh**		Updates all layouts using this library.
	void	**register**	(string name)	Registers the library with the given name
[const]	string[]	**technologies**		Gets the list of technologies this library is associated with.
	void	**technology=**	(string technology)	sets the name of the technology the library is associated with

Public static methods and constants

Library ptr	**library_by_id**	(unsigned long id)	Gets the library object for the given ID
Library ptr	**library_by_name**	(string name, string for_technology = unspecific)	Gets a library by name
unsigned long[]	**library_ids**		Returns a list of valid library IDs.
string[]	**library_names**		Returns a list of the names of all libraries registered in the system.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead
	string	**technology**	Use of this method is deprecated

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

	Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
_destroy	**Signature**: void **_destroy** **Description**: Explicitly destroys the object Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
_destroyed?	**Signature**: *[const]* bool **_destroyed?** **Description**: Returns a value indicating whether the object was already destroyed This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
_is_const_object?	**Signature**: *[const]* bool **_is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference This method returns true, if self is a const reference. In that case, only const methods may be called on self.
_manage	**Signature**: void **_manage** **Description**: Marks the object as managed by the script side. After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required. Usually it's not required to call this method. It has been introduced in version 0.24.
_unmanage	**Signature**: void **_unmanage** **Description**: Marks the object as no longer owned by the script side. Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.
add_technology	**Signature**: void **add_technology** (string tech) **Description**: Additionally associates the library with the given technology. See also clear_technologies. This method has been introduced in version 0.27
assign	**Signature**: void **assign** (const Library other) **Description**: Assigns another object to self
clear_technologies	**Signature**: void **clear_technologies** **Description**: Clears the list of technologies the library is associated with.

See also add_technology.

This method has been introduced in version 0.27

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

delete

Signature: void **delete**

Description: Deletes the library

This method will delete the library object. Library proxies pointing to this library will become invalid and the library object cannot be used any more after calling this method.

This method has been introduced in version 0.25.

description

Signature: *[const]* string **description**

Description: Returns the libraries' description text

Python specific notes:
The object exposes a readable attribute 'description'. This is the getter.

description=

Signature: void **description=** (string description)

Description: Sets the libraries' description text

Python specific notes:
The object exposes a writable attribute 'description'. This is the setter.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new Library ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

for_technologies

Signature: *[const]* bool **for_technologies**

Description: Returns a value indicating whether the library is associated with any technology.

	The method is equivalent to checking whether the technologies list is empty. This method has been introduced in version 0.27
id	**Signature**: *[const]* unsigned long **id** **Description**: Returns the library's ID The ID is set when the library is registered and cannot be changed
is_const_object?	**Signature**: *[const]* bool **is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.
is_for_technology	**Signature**: *[const]* bool **is_for_technology** (string tech) **Description**: Returns a value indicating whether the library is associated with the given technology. This method has been introduced in version 0.27
layout	**Signature**: Layout **layout** **Description**: The layout object where the cells reside that this library defines
layout_const	**Signature**: *[const]* Layout **layout_const** **Description**: The layout object where the cells reside that this library defines (const version)
library_by_id	**Signature**: *[static]* Library ptr **library_by_id** (unsigned long id) **Description**: Gets the library object for the given ID If the ID is not valid, nil is returned. This method has been introduced in version 0.27.
library_by_name	**Signature**: *[static]* Library ptr **library_by_name** (string name, string for_technology = unspecific) **Description**: Gets a library by name Returns the library object for the given name. If the name is not a valid library name, nil is returned. Different libraries can be registered under the same names for different technologies. When a technology name is given in 'for_technologies', the first library matching this technology is returned. If no technology is given, the first library is returned. The technology selector has been introduced in version 0.27.
library_ids	**Signature**: *[static]* unsigned long[] **library_ids** **Description**: Returns a list of valid library IDs. See library_names for the reasoning behind this method. This method has been introduced in version 0.27.
library_names	**Signature**: *[static]* string[] **library_names** **Description**: Returns a list of the names of all libraries registered in the system. NOTE: starting with version 0.27, the name of a library does not need to be unique if libraries are associated with specific technologies. This method will only return the names and it's not possible

not unambiguously derive the library object. It is recommended to use library_ids and library_by_id to obtain the library unambiguously.

name

Signature: *[const]* string **name**

Description: Returns the libraries' name

The name is set when the library is registered and cannot be changed

new

Signature: *[static]* new Library ptr **new**

Description: Creates a new, empty library

Python specific notes:
This method is the default initializer of the object.

refresh

Signature: void **refresh**

Description: Updates all layouts using this library.

This method will retire cells or update layouts in the attached clients. It will also recompute the PCells inside the library. This method has been introduced in version 0.27.8.

register

Signature: void **register** (string name)

Description: Registers the library with the given name

This method can be called in the constructor to register the library after the layout object has been filled with content. If a library with that name already exists for the same technologies, it will be replaced with this library.

This method will set the libraries' name.

The technology specific behaviour has been introduced in version 0.27.

technologies

Signature: *[const]* string[] **technologies**

Description: Gets the list of technologies this library is associated with.

This method has been introduced in version 0.27

technology

Signature: string **technology**

Description: Returns name of the technology the library is associated with

Use of this method is deprecated

If this attribute is a non-empty string, this library is only offered for selection if the current layout uses this technology.

This attribute has been introduced in version 0.25. In version 0.27 this attribute is deprecated as a library can now be associated with multiple technologies.

Python specific notes:
The object exposes a readable attribute 'technology'. This is the getter.

technology=

Signature: void **technology=** (string technology)

Description: sets the name of the technology the library is associated with

See technology for details. This attribute has been introduced in version 0.25. In version 0.27, a library can be associated with multiple technologies and this method will revert the selection to a single one. Passing an empty string is equivalent to clear_technologies.

Python specific notes:
The object exposes a writable attribute 'technology'. This is the setter.

4.57. API reference - Class PCellParameterState

Notation used in Ruby API documentation

Module: db

Description: Provides access to the attributes of a single parameter within \PCellParameterStates.

Sub-classes: ParameterStateIcon

See PCellParameterStates for details about this feature.

This class has been introduced in version 0.28.

Public constructors

new PCellParameterState ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const PCellParameterState other)	Assigns another object to self
[const]	new PCellParameterState ptr	**dup**		Creates a copy of self
	void	**enabled=**	(bool f)	Sets a value indicating whether the parameter is enabled in the parameter form
	void	**icon=**	(PCellParameterStateIcon i)	Sets the icon for the parameter
[const]	bool	**is_enabled?**		Gets a value indicating whether the parameter is enabled in the parameter form
[const]	bool	**is_readonly?**		Gets a value indicating whether the parameter is read-only (not editable) in the parameter form
[const]	bool	**is_visible?**		Gets a value indicating whether the parameter is visible in the parameter form

	void	**readonly=**	(bool f)	Sets a value indicating whether the parameter is made read-only (not editable) in the parameter form
[const]	string	**tooltip**		Gets the tool tip text
[const]	string	**tooltip**		Gets the icon for the parameter
	void	**tooltip=**	(string s)	Sets the tool tip text
[const]	variant	**value**		Gets the value of the parameter
	void	**value=**	(variant v)	Sets the value of the parameter
	void	**visible=**	(bool f)	Sets a value indicating whether the parameter is visible in the parameter form

Public static methods and constants

[static,const]	PCellParameterState::ParameterStateIc	**ErrorIcon**	An icon indicating an error is shown
[static,const]	PCellParameterState::ParameterStateIcon	**InfoIcon**	A general 'information' icon is shown
[static,const]	PCellParameterState::ParameterStateIc	**NoIcon**	No icon is shown for the parameter
[static,const]	PCellParameterState::ParameterStateIcon	**WarningIcon**	An icon indicating a warning is shown

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

ErrorIcon

Signature: *[static,const]* PCellParameterState::ParameterStateIcon **ErrorIcon**

Description: An icon indicating an error is shown

Python specific notes:
The object exposes a readable attribute 'ErrorIcon'. This is the getter.

InfoIcon

Signature: *[static,const]* PCellParameterState::ParameterStateIcon **InfoIcon**

Description: A general 'information' icon is shown

Python specific notes:
The object exposes a readable attribute 'InfoIcon'. This is the getter.

NoIcon

Signature: *[static,const]* PCellParameterState::ParameterStateIcon **NoIcon**

Description: No icon is shown for the parameter

Python specific notes:
The object exposes a readable attribute 'NoIcon'. This is the getter.

WarningIcon

Signature: *[static,const]* PCellParameterState::ParameterStateIcon **WarningIcon**

Description: An icon indicating a warning is shown

Python specific notes:
The object exposes a readable attribute 'WarningIcon'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const PCellParameterState other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new PCellParameterState ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

enabled=

Signature: void **enabled=** (bool f)

Description: Sets a value indicating whether the parameter is enabled in the parameter form

Python specific notes:
The object exposes a writable attribute 'enabled'. This is the setter.

icon=

Signature: void **icon=** (PCellParameterState::ParameterStateIcon i)

Description: Sets the icon for the parameter

Python specific notes:
The object exposes a writable attribute 'icon'. This is the setter.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_enabled?

Signature: *[const]* bool **is_enabled?**

Description: Gets a value indicating whether the parameter is enabled in the parameter form

Python specific notes:
The object exposes a readable attribute 'enabled'. This is the getter.

is_readonly?

Signature: *[const]* bool **is_readonly?**

Description: Gets a value indicating whether the parameter is read-only (not editable) in the parameter form

Python specific notes:
The object exposes a readable attribute 'readonly'. This is the getter.

is_visible?

Signature: *[const]* bool **is_visible?**

Description: Gets a value indicating whether the parameter is visible in the parameter form

Python specific notes:
The object exposes a readable attribute 'visible'. This is the getter.

new

Signature: *[static]* new PCellParameterState ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

readonly=

Signature: void **readonly=** (bool f)

Description: Sets a value indicating whether the parameter is made read-only (not editable) in the parameter form

Python specific notes:
The object exposes a writable attribute 'readonly'. This is the setter.

tooltip

(1) Signature: *[const]* string **tooltip**

Description: Gets the tool tip text

Python specific notes:
The object exposes a readable attribute 'tooltip'. This is the getter.

(2) Signature: *[const]* string **tooltip**

Description: Gets the icon for the parameter

Python specific notes:
This method is available as 'tooltip_' in Python to distiguish it from the property with the same name.

tooltip=

Signature: void **tooltip=** (string s)

Description: Sets the tool tip text

The tool tip is shown when hovering over the parameter label or edit field.

Python specific notes:
The object exposes a writable attribute 'tooltip'. This is the setter.

value

Signature: *[const]* variant **value**

Description: Gets the value of the parameter

Python specific notes:

	The object exposes a readable attribute 'value'. This is the getter.
value=	**Signature**: void **value=** (variant v) **Description**: Sets the value of the parameter **Python specific notes:** The object exposes a writable attribute 'value'. This is the setter.
visible=	**Signature**: void **visible=** (bool f) **Description**: Sets a value indicating whether the parameter is visible in the parameter form **Python specific notes:** The object exposes a writable attribute 'visible'. This is the setter.

4.58. API reference - Class PCellParameterState::ParameterStateIcon

Notation used in Ruby API documentation

Module: db

Description: This enum specifies the icon shown next to the parameter in PCell parameter list.

This class is equivalent to the class PCellParameterState::ParameterStateIcon

This enum was introduced in version 0.28.

Public constructors

new PCellParameterState::ParameterStateIcon ptr	**new**	(int i)	Creates an enum from an integer value
new PCellParameterState::ParameterStateIcon ptr	**new**	(string s)	Creates an enum from a string value

Public methods

[const]	bool	**!=**	(const PCellParameterState::Para other)	Compares two enums for inequality
[const]	bool	**!=**	(int other)	Compares an enum with an integer for inequality
[const]	bool	**<**	(const PCellParameterState::Para other)	Returns true if the first enum is less (in the enum symbol order) than the second
[const]	bool	**<**	(int other)	Returns true if the enum is less (in the enum symbol order) than the integer value
[const]	bool	**==**	(const PCellParameterState::Para other)	Compares two enums
[const]	bool	**==**	(int other)	Compares an enum with an integer value
[const]	int	**hash**		Gets the hash value from the enum
[const]	string	**inspect**		Converts an enum to a visual string
[const]	int	**to_i**		Gets the integer value from the enum
[const]	string	**to_s**		Gets the symbolic string from an enum

Public static methods and constants

[static,const]	PCellParameterState::ParameterStateIc	**ErrorIcon**	An icon indicating an error is shown

[static,const]	PCellParameterState::ParameterStateIcon	**InfoIcon**	A general 'information' icon is shown
[static,const]	PCellParameterState::ParameterStateIc	**NoIcon**	No icon is shown for the parameter
[static,const]	PCellParameterState::ParameterStateIcon	**WarningIcon**	An icon indicating a warning is shown

Detailed description

!=	**(1) Signature**: *[const]* bool **!=** (const PCellParameterState::ParameterStateIcon other) **Description**: Compares two enums for inequality **(2) Signature**: *[const]* bool **!=** (int other) **Description**: Compares an enum with an integer for inequality
<	**(1) Signature**: *[const]* bool **<** (const PCellParameterState::ParameterStateIcon other) **Description**: Returns true if the first enum is less (in the enum symbol order) than the second **(2) Signature**: *[const]* bool **<** (int other) **Description**: Returns true if the enum is less (in the enum symbol order) than the integer value
==	**(1) Signature**: *[const]* bool **==** (const PCellParameterState::ParameterStateIcon other) **Description**: Compares two enums **(2) Signature**: *[const]* bool **==** (int other) **Description**: Compares an enum with an integer value
ErrorIcon	**Signature**: *[static,const]* PCellParameterState::ParameterStateIcon **ErrorIcon** **Description**: An icon indicating an error is shown **Python specific notes:** The object exposes a readable attribute 'ErrorIcon'. This is the getter.
InfoIcon	**Signature**: *[static,const]* PCellParameterState::ParameterStateIcon **InfoIcon** **Description**: A general 'information' icon is shown **Python specific notes:** The object exposes a readable attribute 'InfoIcon'. This is the getter.
NoIcon	**Signature**: *[static,const]* PCellParameterState::ParameterStateIcon **NoIcon** **Description**: No icon is shown for the parameter **Python specific notes:** The object exposes a readable attribute 'NoIcon'. This is the getter.
WarningIcon	**Signature**: *[static,const]* PCellParameterState::ParameterStateIcon **WarningIcon** **Description**: An icon indicating a warning is shown **Python specific notes:**

	The object exposes a readable attribute 'WarningIcon'. This is the getter.
hash	**Signature**: *[const]* int **hash** **Description**: Gets the hash value from the enum **Python specific notes:** This method is also available as 'hash(object)'.
inspect	**Signature**: *[const]* string **inspect** **Description**: Converts an enum to a visual string **Python specific notes:** This method is also available as 'repr(object)'.
new	**(1) Signature**: *[static]* new PCellParameterState::ParameterStateIcon ptr **new** (int i) **Description**: Creates an enum from an integer value **Python specific notes:** This method is the default initializer of the object. **(2) Signature**: *[static]* new PCellParameterState::ParameterStateIcon ptr **new** (string s) **Description**: Creates an enum from a string value **Python specific notes:** This method is the default initializer of the object.
to_i	**Signature**: *[const]* int **to_i** **Description**: Gets the integer value from the enum **Python specific notes:** This method is also available as 'int(object)'.
to_s	**Signature**: *[const]* string **to_s** **Description**: Gets the symbolic string from an enum **Python specific notes:** This method is also available as 'str(object)'.

4.59. API reference - Class PCellParameterStates

Notation used in Ruby API documentation

Module: db

Description: Provides access to the parameter states inside a 'callback' implementation of a PCell

Example: enables or disables a parameter 'n' based on the value:

```
n_param = states.parameter("n")
n_param.enabled = n_param.value > 1.0
```

This class has been introduced in version 0.28.

Public constructors

new PCellParameterStates ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const PCellParamet other)	Assigns another object to self
[const]	new PCellParameterStates ptr	**dup**		Creates a copy of self
[const]	bool	**has_parameter?**	(string name)	Gets a value indicating whether a parameter with that name exists
	PCellParameterState	**parameter**	(string name)	Gets the parameter by name

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead

[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const PCellParameterStates other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new PCellParameterStates ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

has_parameter?

Signature: *[const]* bool **has_parameter?** (string name)

Description: Gets a value indicating whether a parameter with that name exists

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new PCellParameterStates ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

parameter

Signature: PCellParameterState **parameter** (string name)

Description: Gets the parameter by name

This will return a PCellParameterState object that can be used to manipulate the parameter state.

4.60. API reference - Class PCellDeclaration

Notation used in Ruby API documentation

Module: db

Description: A PCell declaration providing the parameters and code to produce the PCell

Class hierarchy: PCellDeclaration

A PCell declaration is basically the recipe of how to create a PCell layout from a parameter set. The declaration includes

- Parameters: names, types, default values
- Layers: the layers the PCell wants to create
- Code: a production callback that is called whenever a PCell is instantiated with a certain parameter set
- Display name: the name that is shown for a given PCell instance

All these declarations are implemented by deriving from the PCellDeclaration class and reimplementing the specific methods. Reimplementing the display_name method is optional. The default implementation creates a name from the PCell name plus the parameters.

By supplying the information about the layers it wants to create, KLayout is able to call the production callback with a defined set of the layer ID's which are already mapped to valid actual layout layers.

This class has been introduced in version 0.22.

Public constructors

new PCellDeclaration ptr	**new**		Creates a new object of this class

Public methods

	void	**_assign**	(const PCellDeclaration other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new PCellDeclaration ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.

	void	assign	(const PCellDeclaration other)	Assigns another object to self
[virtual,const]	void	callback	(const Layout layout, string name, PCellParameterStates states)	Indicates a parameter change and allows implementing actions based on the parameter value
[virtual,const]	bool	can_create_from_sha	(const Layout layout, const Shape shape, unsigned int layer)	Returns true, if the PCell can be created from the given shape
[virtual,const]	variant[]	coerce_parameters	(const Layout layout, variant[] input)	Modifies the parameters to match the requirements
[virtual,const]	string	display_text	(variant[] parameters)	Returns the display text for this PCell given a certain parameter set
[const]	new PCellDeclaration ptr	dup		Creates a copy of self
[virtual,const]	LayerInfo[]	get_layers	(variant[] parameters)	Returns a list of layer declarations
[virtual,const]	PCellParameterDeclaration[]	get_parameters		Returns a list of parameter declarations
[const]	unsigned int	id		Gets the integer ID of the PCell declaration
[const]	Layout ptr	layout		Gets the Layout object the PCell is registered in or nil if it is not registered yet.
[const]	string	name		Gets the name of the PCell
[virtual,const]	variant[]	parameters_from_shape	(const Layout layout, const Shape shape, unsigned int layer)	Gets the parameters for the PCell which can replace the given shape
[virtual,const]	void	produce	(const Layout layout, unsigned int[] layer_ids, variant[] parameters, Cell cell)	The production callback
[virtual,const]	Trans	transformation_from_shape	(const Layout layout, const Shape shape,	Gets the instance transformation for the PCell which can replace the given shape

unsigned int layer)

[virtual,const]	bool	**wants_lazy_evaluatic**	Gets a value indicating whether the PCell wants lazy evaluation

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_assign

Signature: void **_assign** (const PCellDeclaration other)

Description: Assigns another object to self

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_dup

Signature: *[const]* new PCellDeclaration ptr **_dup**

Description: Creates a copy of self

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const PCellDeclaration other)

Description: Assigns another object to self

callback

Signature: *[virtual,const]* void **callback** (const Layout layout, string name, PCellParameterStates states)

Description: Indicates a parameter change and allows implementing actions based on the parameter value

layout:	The layout object in which the PCell will be produced
name:	The name of the parameter which has changed or an empty string if all parameters need to be considered
states:	A PCellParameterStates object which can be used to manipulate the parameter states

This method may be reimplemented to implement parameter-specific actions upon value change or button callbacks. Whenever the value of a parameter is changed in the PCell parameter form, this method is called with the name of the parameter in 'name'. The implementation can manipulate values or states (enabled, visible) or parameters using the PCellParameterStates object passed in 'states'.

Initially, this method will be called with an empty parameter name to indicate a global change. The implementation may then consolidate all states. The initial state is build from the 'readonly' (disabled) or 'hidden' (invisible) parameter declarations.

This method is also called when a button-type parameter is present and the button is pressed. In this case the parameter name is the name of the button.

This feature has been introduced in version 0.28.

can_create_from_shape

Signature: *[virtual,const]* bool **can_create_from_shape** (const Layout layout, const Shape shape, unsigned int layer)

Description: Returns true, if the PCell can be created from the given shape

layout:	The layout the shape lives in
shape:	The shape from which a PCell shall be created
layer:	The layer index (in layout) of the shape

KLayout offers a way to convert a shape into a PCell. To test whether the PCell can be created from a shape, it will call this method. If this method returns true, KLayout will use parameters_from_shape

and transformation_from_shape to derive the parameters and instance transformation for the new PCell instance that will replace the shape.

coerce_parameters

Signature: *[virtual,const]* variant[] **coerce_parameters** (const Layout layout, variant[] input)

Description: Modifies the parameters to match the requirements

layout:	The layout object in which the PCell will be produced
input:	The parameters before the modification
Returns:	The modified parameters or an empty array, indicating that no modification was done

This method can be reimplemented to change the parameter set according to some constraints for example. The reimplementation may modify the parameters in a way that they are usable for the produce method.

The method receives a reference to the layout so it is able to verify the parameters against layout properties.

It can raise an exception to indicate that something is not correct.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

display_text

Signature: *[virtual,const]* string **display_text** (variant[] parameters)

Description: Returns the display text for this PCell given a certain parameter set

Reimplement this method to create a distinct display text for a PCell variant with the given parameter set. If this method is not implemented, a default text is created.

dup

Signature: *[const]* new PCellDeclaration ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

get_layers

Signature: *[virtual,const]* LayerInfo[] **get_layers** (variant[] parameters)

Description: Returns a list of layer declarations

Reimplement this method to return a list of layers this PCell wants to create. The layer declarations are returned as a list of LayerInfo objects which are used as match expressions to look up the layer in the actual layout.

This method receives the PCell parameters which allows it to deduce layers from the parameters.

get_parameters

Signature: *[virtual,const]* PCellParameterDeclaration[] **get_parameters**

Description: Returns a list of parameter declarations

Reimplement this method to return a list of parameters used in that PCell implementation. A parameter declaration is a PCellParameterDeclaration object and defines the parameter name, type, description text and possible choices for the parameter value.

id

Signature: *[const]* unsigned int **id**

Description: Gets the integer ID of the PCell declaration

This ID is used to identify the PCell in the context of a Layout object for example

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

layout

Signature: *[const]* Layout ptr **layout**

Description: Gets the Layout object the PCell is registered in or nil if it is not registered yet.

This attribute has been added in version 0.27.5.

name

Signature: *[const]* string **name**

Description: Gets the name of the PCell

new

Signature: *[static]* new PCellDeclaration ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

parameters_from_shape

Signature: *[virtual,const]* variant[] **parameters_from_shape** (const Layout layout, const Shape shape, unsigned int layer)

Description: Gets the parameters for the PCell which can replace the given shape

layout:	The layout the shape lives in
shape:	The shape from which a PCell shall be created
layer:	The layer index (in layout) of the shape

KLayout offers a way to convert a shape into a PCell. If can_create_from_shape returns true, it will use this method to derive the parameters for the PCell instance that will replace the shape. See also transformation_from_shape and can_create_from_shape.

produce

Signature: *[virtual,const]* void **produce** (const Layout layout, unsigned int[] layer_ids, variant[] parameters, Cell cell)

Description: The production callback

layout:	The layout object where the cell resides
layer_ids:	A list of layer ID's which correspond to the layers declared with get_layers
parameters:	A list of parameter values which correspond to the parameters declared with get_parameters
cell:	The cell where the layout will be created

Reimplement this method to provide the code that implements the PCell. The code is supposed to create the layout in the target cell using the provided parameters and the layers passed in the layer_ids list.

transformation_from_shap

Signature: *[virtual,const]* Trans **transformation_from_shape** (const Layout layout, const Shape shape, unsigned int layer)

Description: Gets the instance transformation for the PCell which can replace the given shape

layout:	The layout the shape lives in
shape:	The shape from which a PCell shall be created
layer:	The layer index (in layout) of the shape

KLayout offers a way to convert a shape into a PCell. If can_create_from_shape returns true, it will use this method to derive the transformation for the PCell instance that will replace the shape. See also parameters_from_shape and can_create_from_shape.

wants_lazy_evaluation

Signature: *[virtual,const]* bool **wants_lazy_evaluation**

Description: Gets a value indicating whether the PCell wants lazy evaluation

In lazy evaluation mode, the PCell UI will not immediately update the layout when a parameter is changed. Instead, the user has to commit the changes in order to have the parameters updated. This is useful for PCells that take a long time to compute.

The default implementation will return 'false' indicating immediate updates.

This method has been added in version 0.27.6.

4.61. API reference - Class PCellParameterDeclaration

Notation used in Ruby API documentation

Module: db

Description: A PCell parameter declaration

This class declares a PCell parameter by providing a name, the type and a value and additional information like description, unit string and default value. It is used in the PCellDeclaration class to deliver the necessary information.

This class has been introduced in version 0.22.

Public constructors

new PCellParameterDeclaration ptr	**new**	(string name, unsigned int type, string description, variant default = nil, string unit =)	Create a new parameter declaration with the given name, type, default value and unit string

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**add_choice**	(string description, variant value)	Add a new value to the list of choices
	void	**assign**	(const PCellParameterDeclaration other)	Assigns another object to self
[const]	string[]	**choice_descriptions**		Returns a list of choice descriptions
[const]	variant[]	**choice_values**		Returns a list of choice values
	void	**clear_choices**		Clears the list of choices
[const]	variant	**default**		Gets the default value
	void	**default=**	(variant value)	Sets the default value
[const]	string	**description**		Gets the description text

	void	**description=**	(string description)	Sets the description
[const]	new PCellParameterDeclaration ptr	**dup**		Creates a copy of self
	void	**hidden=**	(bool flag)	Makes the parameter hidden if this attribute is set to true
[const]	bool	**hidden?**		Returns true, if the parameter is a hidden parameter that should not be shown in the user interface
[const]	variant	**max_value**		Gets the maximum value allowed
	void	**max_value=**	(variant value)	Sets the maximum value allowed
[const]	variant	**min_value**		Gets the minimum value allowed
	void	**min_value=**	(variant value)	Sets the minimum value allowed
[const]	string	**name**		Gets the name
	void	**name=**	(string value)	Sets the name
	void	**readonly=**	(bool flag)	Makes the parameter read-only if this attribute is set to true
[const]	bool	**readonly?**		Returns true, if the parameter is a read-only parameter
[const]	unsigned int	**type**		Gets the type
	void	**type=**	(unsigned int type)	Sets the type
[const]	string	**unit**		Gets the unit string
	void	**unit=**	(string unit)	Sets the unit string

Public static methods and constants

unsigned int	**TypeBoolean**	Type code: boolean data
unsigned int	**TypeCallback**	Type code: a button triggering a callback
unsigned int	**TypeDouble**	Type code: floating-point data
unsigned int	**TypeInt**	Type code: integer data
unsigned int	**TypeLayer**	Type code: a layer (a LayerInfo object)
unsigned int	**TypeList**	Type code: a list of variants
unsigned int	**TypeNone**	Type code: unspecific type

unsigned int	**TypeShape**	Type code: a guiding shape (Box, Edge, Point, Polygon or Path)
unsigned int	**TypeString**	Type code: string data

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

TypeBoolean

Signature: *[static]* unsigned int **TypeBoolean**

Description: Type code: boolean data

Python specific notes:
The object exposes a readable attribute 'TypeBoolean'. This is the getter.

TypeCallback

Signature: *[static]* unsigned int **TypeCallback**

Description: Type code: a button triggering a callback

This code has been introduced in version 0.28.

Python specific notes:
The object exposes a readable attribute 'TypeCallback'. This is the getter.

TypeDouble

Signature: *[static]* unsigned int **TypeDouble**

Description: Type code: floating-point data

Python specific notes:
The object exposes a readable attribute 'TypeDouble'. This is the getter.

TypeInt

Signature: *[static]* unsigned int **TypeInt**

Description: Type code: integer data

Python specific notes:
The object exposes a readable attribute 'TypeInt'. This is the getter.

TypeLayer

Signature: *[static]* unsigned int **TypeLayer**

Description: Type code: a layer (a LayerInfo object)

Python specific notes:
The object exposes a readable attribute 'TypeLayer'. This is the getter.

TypeList

Signature: *[static]* unsigned int **TypeList**

Description: Type code: a list of variants

Python specific notes:

The object exposes a readable attribute 'TypeList'. This is the getter.

TypeNone

Signature: *[static]* unsigned int **TypeNone**

Description: Type code: unspecific type

Python specific notes:
The object exposes a readable attribute 'TypeNone'. This is the getter.

TypeShape

Signature: *[static]* unsigned int **TypeShape**

Description: Type code: a guiding shape (Box, Edge, Point, Polygon or Path)

Python specific notes:
The object exposes a readable attribute 'TypeShape'. This is the getter.

TypeString

Signature: *[static]* unsigned int **TypeString**

Description: Type code: string data

Python specific notes:
The object exposes a readable attribute 'TypeString'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage	**Signature**: void **_unmanage** **Description**: Marks the object as no longer owned by the script side. Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.
add_choice	**Signature**: void **add_choice** (string description, variant value) **Description**: Add a new value to the list of choices This method will add the given value with the given description to the list of choices. If choices are defined, KLayout will show a drop-down box instead of an entry field in the parameter user interface.
assign	**Signature**: void **assign** (const PCellParameterDeclaration other) **Description**: Assigns another object to self
choice_descriptions	**Signature**: *[const]* string[] **choice_descriptions** **Description**: Returns a list of choice descriptions
choice_values	**Signature**: *[const]* variant[] **choice_values** **Description**: Returns a list of choice values
clear_choices	**Signature**: void **clear_choices** **Description**: Clears the list of choices
create	**Signature**: void **create** **Description**: Ensures the C++ object is created Use of this method is deprecated. Use _create instead Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
default	**Signature**: *[const]* variant **default** **Description**: Gets the default value **Python specific notes:** The object exposes a readable attribute 'default'. This is the getter.
default=	**Signature**: void **default=** (variant value) **Description**: Sets the default value If a default value is defined, it will be used to initialize the parameter value when a PCell is created. **Python specific notes:** The object exposes a writable attribute 'default'. This is the setter.

description

Signature: *[const]* string **description**

Description: Gets the description text

Python specific notes:
The object exposes a readable attribute 'description'. This is the getter.

description=

Signature: void **description=** (string description)

Description: Sets the description

Python specific notes:
The object exposes a writable attribute 'description'. This is the setter.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new PCellParameterDeclaration ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

hidden=

Signature: void **hidden=** (bool flag)

Description: Makes the parameter hidden if this attribute is set to true

Python specific notes:
The object exposes a writable attribute 'hidden'. This is the setter.

hidden?

Signature: *[const]* bool **hidden?**

Description: Returns true, if the parameter is a hidden parameter that should not be shown in the user interface

By making a parameter hidden, it is possible to create internal parameters which cannot be edited.

Python specific notes:
The object exposes a readable attribute 'hidden'. This is the getter.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

max_value

Signature: *[const]* variant **max_value**

Description: Gets the maximum value allowed

See max_value= for a description of this attribute.

This attribute has been added in version 0.29.

Python specific notes:
The object exposes a readable attribute 'max_value'. This is the getter.

max_value=

Signature: void **max_value=** (variant value)

Description: Sets the maximum value allowed

The maximum value is a visual feature and limits the allowed values for numerical entry boxes. This applies to parameters of type int or double. The maximum value is not effective if choices are present.

The maximum value is not enforced - for example there is no restriction implemented when setting values programmatically.

Setting this attribute to "nil" (the default) implies "no limit".

This attribute has been added in version 0.29.

Python specific notes:
The object exposes a writable attribute 'max_value'. This is the setter.

min_value

Signature: *[const]* variant **min_value**

Description: Gets the minimum value allowed

See min_value= for a description of this attribute.

This attribute has been added in version 0.29.

Python specific notes:
The object exposes a readable attribute 'min_value'. This is the getter.

min_value=

Signature: void **min_value=** (variant value)

Description: Sets the minimum value allowed

The minimum value is a visual feature and limits the allowed values for numerical entry boxes. This applies to parameters of type int or double. The minimum value is not effective if choices are present.

The minimum value is not enforced - for example there is no restriction implemented when setting values programmatically.

Setting this attribute to "nil" (the default) implies "no limit".

This attribute has been added in version 0.29.

Python specific notes:
The object exposes a writable attribute 'min_value'. This is the setter.

name

Signature: *[const]* string **name**

Description: Gets the name

Python specific notes:
The object exposes a readable attribute 'name'. This is the getter.

name=

Signature: void **name=** (string value)

Description: Sets the name

Python specific notes:

The object exposes a writable attribute 'name'. This is the setter.

new

Signature: *[static]* new PCellParameterDeclaration ptr **new** (string name, unsigned int type, string description, variant default = nil, string unit =)

Description: Create a new parameter declaration with the given name, type, default value and unit string

name:	The parameter name
type:	One of the Type... constants describing the type of the parameter
description:	The description text
default:	The default (initial) value
unit:	The unit string

Python specific notes:
This method is the default initializer of the object.

readonly=

Signature: void **readonly=** (bool flag)

Description: Makes the parameter read-only if this attribute is set to true

Python specific notes:
The object exposes a writable attribute 'readonly'. This is the setter.

readonly?

Signature: *[const]* bool **readonly?**

Description: Returns true, if the parameter is a read-only parameter

By making a parameter read-only, it is shown but cannot be edited.

Python specific notes:
The object exposes a readable attribute 'readonly'. This is the getter.

type

Signature: *[const]* unsigned int **type**

Description: Gets the type

The type is one of the T... constants.

Python specific notes:
The object exposes a readable attribute 'type'. This is the getter.

type=

Signature: void **type=** (unsigned int type)

Description: Sets the type

Python specific notes:
The object exposes a writable attribute 'type'. This is the setter.

unit

Signature: *[const]* string **unit**

Description: Gets the unit string

Python specific notes:
The object exposes a readable attribute 'unit'. This is the getter.

unit=

Signature: void **unit=** (string unit)

Description: Sets the unit string

The unit string is shown right to the edit fields for numeric parameters.

Python specific notes:

The object exposes a writable attribute 'unit'. This is the setter.

4.62. API reference - Class LogEntryData

Notation used in Ruby API documentation

Module: db

Description: A generic log entry

This class is used for example by the device extractor (see NetlistDeviceExtractor) to keep errors or warnings that occurred during extraction of the devices.

Other classes also make use of this object to store errors, warnings or information. The log entry object features a severity (warning, error, info), a message, an optional category name and description (good for filtering if needed) and an optional DPolygon object for indicating some location or error marker. The original class used to be "NetlistDeviceExtractorError" which had been introduced in version 0.26. It was generalized and renamed in version 0.28.13 as it was basically not useful as a separate class.

Public constructors

new LogEntryData ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const LogEntryData other)	Assigns another object to self
[const]	string	**category_description**		Gets the category description.
	void	**category_description=**	(string description)	Sets the category description.
[const]	string	**category_name**		Gets the category name.
	void	**category_name=**	(string name)	Sets the category name.
[const]	string	**cell_name**		Gets the cell name.
	void	**cell_name=**	(string cell_name)	Sets the cell name.
[const]	new LogEntryData ptr	**dup**		Creates a copy of self

[const]	DPolygon	**geometry**		Gets the geometry.
	void	**geometry=**	(const DPolygon polygon)	Sets the geometry.
[const]	string	**message**		Gets the message text.
	void	**message=**	(string message)	Sets the message text.
[const]	Severity	**severity**		Gets the severity attribute.
	void	**severity=**	(Severity severity)	Sets the severity attribute.
[const]	string	**to_s**	(bool with_geometry = true)	Gets the string representation of this error or warning.

Public static methods and constants

[static,const]	Severity	**Error**	Specifies error severity (preferred action is stop)
[static,const]	Severity	**Info**	Specifies info severity (print if requested, otherwise silent)
[static,const]	Severity	**NoSeverity**	Specifies no particular severity (default)
[static,const]	Severity	**Warning**	Specifies warning severity (log with high priority, but do not stop)

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

Error

Signature: *[static,const]* Severity **Error**

Description: Specifies error severity (preferred action is stop)

Python specific notes:
The object exposes a readable attribute 'Error'. This is the getter.

Info

Signature: *[static,const]* Severity **Info**

Description: Specifies info severity (print if requested, otherwise silent)

Python specific notes:

The object exposes a readable attribute 'Info'. This is the getter.

NoSeverity

Signature: *[static,const]* Severity **NoSeverity**

Description: Specifies no particular severity (default)

Python specific notes:
The object exposes a readable attribute 'NoSeverity'. This is the getter.

Warning

Signature: *[static,const]* Severity **Warning**

Description: Specifies warning severity (log with high priority, but do not stop)

Python specific notes:
The object exposes a readable attribute 'Warning'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the

	reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.
assign	**Signature**: void **assign** (const LogEntryData other) **Description**: Assigns another object to self
category_description	**Signature**: *[const]* string **category_description** **Description**: Gets the category description. See category_name= for details about categories. **Python specific notes:** The object exposes a readable attribute 'category_description'. This is the getter.
category_description=	**Signature**: void **category_description=** (string description) **Description**: Sets the category description. See category_name= for details about categories. **Python specific notes:** The object exposes a writable attribute 'category_description'. This is the setter.
category_name	**Signature**: *[const]* string **category_name** **Description**: Gets the category name. See category_name= for more details. **Python specific notes:** The object exposes a readable attribute 'category_name'. This is the getter.
category_name=	**Signature**: void **category_name=** (string name) **Description**: Sets the category name. The category name is optional. If given, it specifies a formal category name. Errors with the same category name are shown in that category. If in addition a category description is specified (see category_description), this description will be displayed as the title. **Python specific notes:** The object exposes a writable attribute 'category_name'. This is the setter.
cell_name	**Signature**: *[const]* string **cell_name** **Description**: Gets the cell name. See cell_name= for details about this attribute. **Python specific notes:** The object exposes a readable attribute 'cell_name'. This is the getter.
cell_name=	**Signature**: void **cell_name=** (string cell_name) **Description**: Sets the cell name. The cell (or circuit) name specifies the cell or circuit the log entry is related to. If the log entry is an error or warning generated during device extraction, the cell name is the circuit the device should have appeared in. **Python specific notes:** The object exposes a writable attribute 'cell_name'. This is the setter.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new LogEntryData ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

geometry

Signature: *[const]* DPolygon **geometry**

Description: Gets the geometry.

See geometry= for more details.

Python specific notes:
The object exposes a readable attribute 'geometry'. This is the getter.

geometry=

Signature: void **geometry=** (const DPolygon polygon)

Description: Sets the geometry.

The geometry is optional. If given, a marker may be shown when selecting this error.

Python specific notes:
The object exposes a writable attribute 'geometry'. This is the setter.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

message

Signature: *[const]* string **message**

Description: Gets the message text.

Python specific notes:

	The object exposes a readable attribute 'message'. This is the getter.
message=	**Signature**: void **message=** (string message) **Description**: Sets the message text. **Python specific notes:** The object exposes a writable attribute 'message'. This is the setter.
new	**Signature**: *[static]* new LogEntryData ptr **new** **Description**: Creates a new object of this class **Python specific notes:** This method is the default initializer of the object.
severity	**Signature**: *[const]* Severity **severity** **Description**: Gets the severity attribute. **Python specific notes:** The object exposes a readable attribute 'severity'. This is the getter.
severity=	**Signature**: void **severity=** (Severity severity) **Description**: Sets the severity attribute. **Python specific notes:** The object exposes a writable attribute 'severity'. This is the setter.
to_s	**Signature**: *[const]* string **to_s** (bool with_geometry = true) **Description**: Gets the string representation of this error or warning. This method has been introduced in version 0.28.13. **Python specific notes:** This method is also available as 'str(object)'.

4.63. API reference - Class Severity

Notation used in Ruby API documentation

Module: db

Description: This enum specifies the severity level for log entries.

This enum was introduced in version 0.28.13.

Public constructors

new Severity ptr	**new**	(int i)	Creates an enum from an integer value
new Severity ptr	**new**	(string s)	Creates an enum from a string value

Public methods

[const]	bool	**!=**	(const Severity other)	Compares two enums for inequality
[const]	bool	**!=**	(int other)	Compares an enum with an integer for inequality
[const]	bool	**<**	(const Severity other)	Returns true if the first enum is less (in the enum symbol order) than the second
[const]	bool	**<**	(int other)	Returns true if the enum is less (in the enum symbol order) than the integer value
[const]	bool	**==**	(const Severity other)	Compares two enums
[const]	bool	**==**	(int other)	Compares an enum with an integer value
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const Severity other)	Assigns another object to self
[const]	new Severity ptr	**dup**		Creates a copy of self

[const]	int	**hash**	Gets the hash value from the enum
[const]	string	**inspect**	Converts an enum to a visual string
[const]	int	**to_i**	Gets the integer value from the enum
[const]	string	**to_s**	Gets the symbolic string from an enum

Public static methods and constants

[static,const]	Severity	**Error**	Specifies error severity (preferred action is stop)
[static,const]	Severity	**Info**	Specifies info severity (print if requested, otherwise silent)
[static,const]	Severity	**NoSeverity**	Specifies no particular severity (default)
[static,const]	Severity	**Warning**	Specifies warning severity (log with high priority, but do not stop)

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

!=	**(1) Signature**: *[const]* bool **!=** (const Severity other) **Description**: Compares two enums for inequality **(2) Signature**: *[const]* bool **!=** (int other) **Description**: Compares an enum with an integer for inequality
<	**(1) Signature**: *[const]* bool **<** (const Severity other) **Description**: Returns true if the first enum is less (in the enum symbol order) than the second **(2) Signature**: *[const]* bool **<** (int other) **Description**: Returns true if the enum is less (in the enum symbol order) than the integer value
==	**(1) Signature**: *[const]* bool **==** (const Severity other) **Description**: Compares two enums **(2) Signature**: *[const]* bool **==** (int other)

Description: Compares an enum with an integer value

Error

Signature: *[static,const]* Severity **Error**

Description: Specifies error severity (preferred action is stop)

Python specific notes:
The object exposes a readable attribute 'Error'. This is the getter.

Info

Signature: *[static,const]* Severity **Info**

Description: Specifies info severity (print if requested, otherwise silent)

Python specific notes:
The object exposes a readable attribute 'Info'. This is the getter.

NoSeverity

Signature: *[static,const]* Severity **NoSeverity**

Description: Specifies no particular severity (default)

Python specific notes:
The object exposes a readable attribute 'NoSeverity'. This is the getter.

Warning

Signature: *[static,const]* Severity **Warning**

Description: Specifies warning severity (log with high priority, but do not stop)

Python specific notes:
The object exposes a readable attribute 'Warning'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const Severity other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new Severity ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

hash

Signature: *[const]* int **hash**

Description: Gets the hash value from the enum

Python specific notes:

	This method is also available as 'hash(object)'.
inspect	**Signature**: *[const]* string **inspect** **Description**: Converts an enum to a visual string **Python specific notes:** This method is also available as 'repr(object)'.
is_const_object?	**Signature**: *[const]* bool **is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.
new	**(1) Signature**: *[static]* new Severity ptr **new** (int i) **Description**: Creates an enum from an integer value **Python specific notes:** This method is the default initializer of the object. **(2) Signature**: *[static]* new Severity ptr **new** (string s) **Description**: Creates an enum from a string value **Python specific notes:** This method is the default initializer of the object.
to_i	**Signature**: *[const]* int **to_i** **Description**: Gets the integer value from the enum **Python specific notes:** This method is also available as 'int(object)'.
to_s	**Signature**: *[const]* string **to_s** **Description**: Gets the symbolic string from an enum **Python specific notes:** This method is also available as 'str(object)'.

4.64. API reference - Class Manager

Notation used in Ruby API documentation

Module: db

Description: A transaction manager class

Manager objects control layout and potentially other objects in the layout database and queue operations to form transactions. A transaction is a sequence of operations that can be undone or redone.

In order to equip a layout object with undo/redo support, instantiate the layout object with a manager attached and embrace the operations to undo/redo with transaction/commit calls.

The use of transactions is subject to certain constraints, i.e. transacted sequences may not be mixed with non-transacted ones.

This class has been introduced in version 0.19.

Public constructors

new Manager ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const Manager other)	Assigns another object to self
	void	**commit**		Close a transaction.
[const]	new Manager ptr	**dup**		Creates a copy of self
[const]	bool	**has_redo?**		Determine if a transaction is available for 'redo'
[const]	bool	**has_undo?**		Determine if a transaction is available for 'undo'
	void	**redo**		Redo the next available transaction
	unsigned long	**transaction**	(string description)	Begin a transaction
	unsigned long	**transaction**	(string description,	Begin a joined transaction

		unsigned long join_with)	
[const]	string	**transaction_for_redo**	Return the description of the next transaction for 'redo'
[const]	string	**transaction_for_undo**	Return the description of the next transaction for 'undo'
	void	**undo**	Undo the current transaction

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const Manager other)

Description: Assigns another object to self

commit

Signature: void **commit**

Description: Close a transaction.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new Manager ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

has_redo?

Signature: *[const]* bool **has_redo?**

Description: Determine if a transaction is available for 'redo'

Returns: True, if a transaction is available.

has_undo?

Signature: *[const]* bool **has_undo?**

Description: Determine if a transaction is available for 'undo'

Returns: True, if a transaction is available.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new Manager ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

redo

Signature: void **redo**

Description: Redo the next available transaction

The next transaction is redone with this method. The 'has_redo' method can be used to determine whether there are transactions to undo.

transaction

(1) Signature: unsigned long **transaction** (string description)

Description: Begin a transaction

description: The description for this transaction.

Returns: The ID of the transaction (can be used to join other transactions with this one)

This call will open a new transaction. A transaction consists of a set of operations issued with the 'queue' method. A transaction is closed with the 'commit' method.

(2) Signature: unsigned long **transaction** (string description, unsigned long join_with)

Description: Begin a joined transaction

description: The description for this transaction (ignored if joined).

description: The ID of the previous transaction.

Returns: The ID of the new transaction (can be used to join more)

This call will open a new transaction and join if with the previous transaction. The ID of the previous transaction must be equal to the ID given with 'join_with'.

This overload was introduced in version 0.22.

transaction_for_redo

Signature: *[const]* string **transaction_for_redo**

Description: Return the description of the next transaction for 'redo'

transaction_for_undo	**Signature**: *[const]* string **transaction_for_undo** **Description**: Return the description of the next transaction for 'undo'
undo	**Signature**: void **undo** **Description**: Undo the current transaction The current transaction is undone with this method. The 'has_undo' method can be used to determine whether there are transactions to undo.

4.65. API reference - Class Matrix2d

Notation used in Ruby API documentation

Module: db

Description: A 2d matrix object used mainly for representing rotation and shear transformations.

This object represents a 2x2 matrix. This matrix is used to implement affine transformations in the 2d space mainly. It can be decomposed into basic transformations: mirroring, rotation and shear. In that case, the assumed execution order of the basic transformations is mirroring at the x axis, rotation, magnification and shear.

The matrix is a generalization of the transformations and is of limited use in a layout database context. It is useful however to implement shear transformations on polygons, edges and polygon or edge collections.

This class was introduced in version 0.22.

Public constructors

new Matrix2d ptr	**new**		Create a new Matrix2d representing a unit transformation
new Matrix2d ptr	**new**	(double m)	Create a new Matrix2d representing an isotropic magnification
new Matrix2d ptr	**new**	(double mx, double my)	Create a new Matrix2d representing an anisotropic magnification
new Matrix2d ptr	**new**	(const DCplxTrans t)	Create a new Matrix2d from the given complex transformation@param t The transformation from which to create the matrix (not taking into account the displacement)
new Matrix2d ptr	**new**	(double m11, double m12, double m21, double m22)	Create a new Matrix2d from the four coefficients

Public methods

[const]	DPoint	*	(const DPoint p)	Transforms a point with this matrix.
[const]	DVector	*	(const DVector v)	Transforms a vector with this matrix.
[const]	DEdge	*	(const DEdge e)	Transforms an edge with this matrix.
[const]	DBox	*	(const DBox box)	Transforms a box with this matrix.
[const]	DSimplePolygon	*	(const DSimplePolygon p)	Transforms a simple polygon with this matrix.
[const]	DPolygon	*	(const DPolygon p)	Transforms a polygon with this matrix.

[const]	Matrix2d	*****	(const Matrix2d m)	Product of two matrices.
[const]	Matrix2d	**+**	(const Matrix2d m)	Sum of two matrices.
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	double	**angle**		Returns the rotation angle of the rotation component of this matrix.
	void	**assign**	(const Matrix2d other)	Assigns another object to self
[const]	DCplxTrans	**cplx_trans**		Converts this matrix to a complex transformation (if possible).
[const]	new Matrix2d ptr	**dup**		Creates a copy of self
[const]	Matrix2d	**inverted**		The inverse of this matrix.
[const]	bool	**is_mirror?**		Returns the mirror flag of this matrix.
[const]	double	**m**	(int i, int j)	Gets the m coefficient with the given index.
[const]	double	**m11**		Gets the m11 coefficient.
[const]	double	**m12**		Gets the m12 coefficient.
[const]	double	**m21**		Gets the m21 coefficient.
[const]	double	**m22**		Gets the m22 coefficient.
[const]	double	**mag_x**		Returns the x magnification of the magnification component of this matrix.
[const]	double	**mag_y**		Returns the y magnification of the magnification component of this matrix.
[const]	double	**shear_angle**		Returns the magnitude of the shear component of this matrix.
[const]	string	**to_s**		Convert the matrix to a string.

[const]	DPoint	**trans**	(const DPoint p)	Transforms a point with this matrix.

Public static methods and constants

	new Matrix2d ptr	**newc**	(double mag, double rotation, bool mirror)	Create a new Matrix2d representing an isotropic magnification, rotation and mirroring
	new Matrix2d ptr	**newc**	(double shear, double mx, double my, double rotation, bool mirror)	Create a new Matrix2d representing a shear, anisotropic magnification, rotation and mirroring

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

*****

(1) Signature: *[const]* DPoint ***** (const DPoint p)

Description: Transforms a point with this matrix.

p: The point to transform.

Returns: The transformed point

Python specific notes:
This method also implements '__rmul__'.

(2) Signature: *[const]* DVector ***** (const DVector v)

Description: Transforms a vector with this matrix.

v: The vector to transform.

Returns: The transformed vector

Python specific notes:
This method also implements '__rmul__'.

(3) Signature: *[const]* DEdge ***** (const DEdge e)

Description: Transforms an edge with this matrix.

e: The edge to transform.

Returns: The transformed edge

Python specific notes:
This method also implements '__rmul__'.

(4) Signature: *[const]* DBox ***** (const DBox box)

Description: Transforms a box with this matrix.

box:	The box to transform.
Returns:	The transformed box

Please note that the box remains a box, even though the matrix supports shear and rotation. The returned box will be the bounding box of the sheared and rotated rectangle.

Python specific notes:
This method also implements '__rmul__'.

(5) Signature: *[const]* DSimplePolygon ***** (const DSimplePolygon p)

Description: Transforms a simple polygon with this matrix.

p:	The simple polygon to transform.
Returns:	The transformed simple polygon

Python specific notes:
This method also implements '__rmul__'.

(6) Signature: *[const]* DPolygon ***** (const DPolygon p)

Description: Transforms a polygon with this matrix.

p:	The polygon to transform.
Returns:	The transformed polygon

Python specific notes:
This method also implements '__rmul__'.

(7) Signature: *[const]* Matrix2d ***** (const Matrix2d m)

Description: Product of two matrices.

m:	The other matrix.
Returns:	The matrix product self*m

Python specific notes:
This method also implements '__rmul__'.

+

Signature: *[const]* Matrix2d **+** (const Matrix2d m)

Description: Sum of two matrices.

m:	The other matrix.
Returns:	The (element-wise) sum of self+m

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

angle

Signature: *[const]* double **angle**

Description: Returns the rotation angle of the rotation component of this matrix.

Returns: The angle in degree.

The matrix is decomposed into basic transformations assuming an execution order of mirroring at the x axis, rotation, magnification and shear.

assign

Signature: void **assign** (const Matrix2d other)

Description: Assigns another object to self

cplx_trans

Signature: *[const]* DCplxTrans **cplx_trans**

Description: Converts this matrix to a complex transformation (if possible).

Returns: The complex transformation.

This method is successful only if the matrix does not contain shear components and the magnification must be isotropic.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new Matrix2d ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

inverted

Signature: *[const]* Matrix2d **inverted**

Description: The inverse of this matrix.

Returns: The inverse of this matrix

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_mirror?

Signature: *[const]* bool **is_mirror?**

Description: Returns the mirror flag of this matrix.

Returns: True if this matrix has a mirror component.

The matrix is decomposed into basic transformations assuming an execution order of mirroring at the x axis, rotation, magnification and shear.

m

Signature: *[const]* double **m** (int i, int j)

Description: Gets the m coefficient with the given index.

Returns: The coefficient [i,j]

m11

Signature: *[const]* double **m11**

Description: Gets the m11 coefficient.

Returns: The value of the m11 coefficient

m12

Signature: *[const]* double **m12**

Description: Gets the m12 coefficient.

Returns: The value of the m12 coefficient

m21

Signature: *[const]* double **m21**

Description: Gets the m21 coefficient.

Returns: The value of the m21 coefficient

m22

Signature: *[const]* double **m22**

Description: Gets the m22 coefficient.

Returns: The value of the m22 coefficient

mag_x

Signature: *[const]* double **mag_x**

Description: Returns the x magnification of the magnification component of this matrix.

Returns: The magnification factor.

The matrix is decomposed into basic transformations assuming an execution order of mirroring at the x axis, magnification, shear and rotation.

mag_y

Signature: *[const]* double **mag_y**

Description: Returns the y magnification of the magnification component of this matrix.

Returns: The magnification factor.

The matrix is decomposed into basic transformations assuming an execution order of mirroring at the x axis, magnification, shear and rotation.

new

(1) Signature: *[static]* new Matrix2d ptr **new**

Description: Create a new Matrix2d representing a unit transformation

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new Matrix2d ptr **new** (double m)

Description: Create a new Matrix2d representing an isotropic magnification

m: The magnification

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new Matrix2d ptr **new** (double mx, double my)

Description: Create a new Matrix2d representing an anisotropic magnification

mx: The magnification in x direction

my: The magnification in y direction

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new Matrix2d ptr **new** (const DCplxTrans t)

Description: Create a new Matrix2d from the given complex transformation@param t The transformation from which to create the matrix (not taking into account the displacement)

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new Matrix2d ptr **new** (double m11, double m12, double m21, double m22)

Description: Create a new Matrix2d from the four coefficients

Python specific notes:
This method is the default initializer of the object.

newc

(1) Signature: *[static]* new Matrix2d ptr **newc** (double mag, double rotation, bool mirror)

Description: Create a new Matrix2d representing an isotropic magnification, rotation and mirroring

mag:	The magnification in x direction
rotation:	The rotation angle (in degree)
mirror:	The mirror flag (at x axis)

This constructor is provided to construct a matrix similar to the complex transformation. This constructor is called 'newc' to distinguish it from the constructors taking matrix coefficients ('c' is for composite). The order of execution of the operations is mirror, magnification, rotation (as for complex transformations).

(2) Signature: *[static]* new Matrix2d ptr **newc** (double shear, double mx, double my, double rotation, bool mirror)

Description: Create a new Matrix2d representing a shear, anisotropic magnification, rotation and mirroring

shear:	The shear angle
mx:	The magnification in x direction
my:	The magnification in y direction
rotation:	The rotation angle (in degree)
mirror:	The mirror flag (at x axis)

The order of execution of the operations is mirror, magnification, shear and rotation. This constructor is called 'newc' to distinguish it from the constructor taking the four matrix coefficients ('c' is for composite).

shear_angle

Signature: *[const]* double **shear_angle**

Description: Returns the magnitude of the shear component of this matrix.

Returns:	The shear angle in degree.

The matrix is decomposed into basic transformations assuming an execution order of mirroring at the x axis, rotation, magnification and shear. The shear basic transformation will tilt the x axis towards the y axis and vice versa. The shear angle gives the tilt angle of the axes towards the other one. The possible range for this angle is -45 to 45 degree.

to_s

Signature: *[const]* string **to_s**

Description: Convert the matrix to a string.

Returns: The string representing this matrix

Python specific notes:
This method is also available as 'str(object)'.

trans

Signature: *[const]* DPoint **trans** (const DPoint p)

Description: Transforms a point with this matrix.

p: The point to transform.

Returns: The transformed point

Python specific notes:
This method also implements '__rmul__'.

4.66. API reference - Class IMatrix2d

Notation used in Ruby API documentation

Module: db

Description: A 2d matrix object used mainly for representing rotation and shear transformations (integer coordinate version).

This object represents a 2x2 matrix. This matrix is used to implement affine transformations in the 2d space mainly. It can be decomposed into basic transformations: mirroring, rotation and shear. In that case, the assumed execution order of the basic transformations is mirroring at the x axis, rotation, magnification and shear.

The integer variant was introduced in version 0.27.

Public constructors

new IMatrix2d ptr	**new**		Create a new Matrix2d representing a unit transformation
new IMatrix2d ptr	**new**	(double m)	Create a new Matrix2d representing an isotropic magnification
new IMatrix2d ptr	**new**	(double mx, double my)	Create a new Matrix2d representing an anisotropic magnification
new IMatrix2d ptr	**new**	(const DCplxTrans t)	Create a new Matrix2d from the given complex transformation@param t The transformation from which to create the matrix (not taking into account the displacement)
new IMatrix2d ptr	**new**	(double m11, double m12, double m21, double m22)	Create a new Matrix2d from the four coefficients

Public methods

[const]	Point	*	(const Point p)	Transforms a point with this matrix.
[const]	Vector	*	(const Vector v)	Transforms a vector with this matrix.
[const]	Edge	*	(const Edge e)	Transforms an edge with this matrix.
[const]	Box	*	(const Box box)	Transforms a box with this matrix.
[const]	SimplePolygon	*	(const SimplePolygon p)	Transforms a simple polygon with this matrix.
[const]	Polygon	*	(const Polygon p)	Transforms a polygon with this matrix.
[const]	IMatrix2d	*	(const IMatrix2d m)	Product of two matrices.

[const]	IMatrix2d	**+**	(const IMatrix2d m)	Sum of two matrices.
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	double	**angle**		Returns the rotation angle of the rotation component of this matrix.
	void	**assign**	(const IMatrix2d other)	Assigns another object to self
[const]	ICplxTrans	**cplx_trans**		Converts this matrix to a complex transformation (if possible).
[const]	new IMatrix2d ptr	**dup**		Creates a copy of self
[const]	IMatrix2d	**inverted**		The inverse of this matrix.
[const]	bool	**is_mirror?**		Returns the mirror flag of this matrix.
[const]	double	**m**	(int i, int j)	Gets the m coefficient with the given index.
[const]	double	**m11**		Gets the m11 coefficient.
[const]	double	**m12**		Gets the m12 coefficient.
[const]	double	**m21**		Gets the m21 coefficient.
[const]	double	**m22**		Gets the m22 coefficient.
[const]	double	**mag_x**		Returns the x magnification of the magnification component of this matrix.
[const]	double	**mag_y**		Returns the y magnification of the magnification component of this matrix.
[const]	double	**shear_angle**		Returns the magnitude of the shear component of this matrix.
[const]	string	**to_s**		Convert the matrix to a string.
[const]	Point	**trans**	(const Point p)	Transforms a point with this matrix.

Public static methods and constants

	new IMatrix2d ptr	**newc**	(double mag, double rotation, bool mirror)	Create a new Matrix2d representing an isotropic magnification, rotation and mirroring
	new IMatrix2d ptr	**newc**	(double shear, double mx, double my, double rotation, bool mirror)	Create a new Matrix2d representing a shear, anisotropic magnification, rotation and mirroring

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

*****

(1) Signature: *[const]* Point ***** (const Point p)

Description: Transforms a point with this matrix.

p: The point to transform.

Returns: The transformed point

Python specific notes:
This method also implements '__rmul__'.

(2) Signature: *[const]* Vector ***** (const Vector v)

Description: Transforms a vector with this matrix.

v: The vector to transform.

Returns: The transformed vector

Python specific notes:
This method also implements '__rmul__'.

(3) Signature: *[const]* Edge ***** (const Edge e)

Description: Transforms an edge with this matrix.

e: The edge to transform.

Returns: The transformed edge

Python specific notes:
This method also implements '__rmul__'.

(4) Signature: *[const]* Box ***** (const Box box)

Description: Transforms a box with this matrix.

box: The box to transform.

Returns: The transformed box

Please note that the box remains a box, even though the matrix supports shear and rotation. The returned box will be the bounding box of the sheared and rotated rectangle.

Python specific notes:
This method also implements '__rmul__'.

(5) Signature: *[const]* SimplePolygon ***** (const SimplePolygon p)

Description: Transforms a simple polygon with this matrix.

p: The simple polygon to transform.

Returns: The transformed simple polygon

Python specific notes:
This method also implements '__rmul__'.

(6) Signature: *[const]* Polygon ***** (const Polygon p)

Description: Transforms a polygon with this matrix.

p: The polygon to transform.

Returns: The transformed polygon

Python specific notes:
This method also implements '__rmul__'.

(7) Signature: *[const]* IMatrix2d ***** (const IMatrix2d m)

Description: Product of two matrices.

m: The other matrix.

Returns: The matrix product self*m

Python specific notes:
This method also implements '__rmul__'.

+

Signature: *[const]* IMatrix2d **+** (const IMatrix2d m)

Description: Sum of two matrices.

m: The other matrix.

Returns: The (element-wise) sum of self+m

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

angle

Signature: *[const]* double **angle**

Description: Returns the rotation angle of the rotation component of this matrix.

Returns: The angle in degree.

The matrix is decomposed into basic transformations assuming an execution order of mirroring at the x axis, rotation, magnification and shear.

assign

Signature: void **assign** (const IMatrix2d other)

Description: Assigns another object to self

cplx_trans

Signature: *[const]* ICplxTrans **cplx_trans**

Description: Converts this matrix to a complex transformation (if possible).

Returns: The complex transformation.

This method is successful only if the matrix does not contain shear components and the magnification must be isotropic.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new IMatrix2d ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

inverted

Signature: *[const]* IMatrix2d **inverted**

Description: The inverse of this matrix.

Returns: The inverse of this matrix

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_mirror?

Signature: *[const]* bool **is_mirror?**

Description: Returns the mirror flag of this matrix.

Returns: True if this matrix has a mirror component.

The matrix is decomposed into basic transformations assuming an execution order of mirroring at the x axis, rotation, magnification and shear.

m

Signature: *[const]* double **m** (int i, int j)

Description: Gets the m coefficient with the given index.

Returns: The coefficient [i,j]

m11

Signature: *[const]* double **m11**

Description: Gets the m11 coefficient.

Returns: The value of the m11 coefficient

m12

Signature: *[const]* double **m12**

Description: Gets the m12 coefficient.

Returns: The value of the m12 coefficient

m21

Signature: *[const]* double **m21**

Description: Gets the m21 coefficient.

Returns: The value of the m21 coefficient

m22

Signature: *[const]* double **m22**

Description: Gets the m22 coefficient.

Returns: The value of the m22 coefficient

mag_x

Signature: *[const]* double **mag_x**

Description: Returns the x magnification of the magnification component of this matrix.

Returns: The magnification factor.

The matrix is decomposed into basic transformations assuming an execution order of mirroring at the x axis, magnification, shear and rotation.

mag_y

Signature: *[const]* double **mag_y**

Description: Returns the y magnification of the magnification component of this matrix.

Returns: The magnification factor.

The matrix is decomposed into basic transformations assuming an execution order of mirroring at the x axis, magnification, shear and rotation.

new

(1) Signature: *[static]* new IMatrix2d ptr **new**

Description: Create a new Matrix2d representing a unit transformation

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new IMatrix2d ptr **new** (double m)

Description: Create a new Matrix2d representing an isotropic magnification

m: The magnification

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new IMatrix2d ptr **new** (double mx, double my)

Description: Create a new Matrix2d representing an anisotropic magnification

mx: The magnification in x direction

my: The magnification in y direction

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new IMatrix2d ptr **new** (const DCplxTrans t)

Description: Create a new Matrix2d from the given complex transformation@param t The transformation from which to create the matrix (not taking into account the displacement)

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new IMatrix2d ptr **new** (double m11, double m12, double m21, double m22)

Description: Create a new Matrix2d from the four coefficients

Python specific notes:
This method is the default initializer of the object.

newc

(1) Signature: *[static]* new IMatrix2d ptr **newc** (double mag, double rotation, bool mirror)

Description: Create a new Matrix2d representing an isotropic magnification, rotation and mirroring

mag:	The magnification in x direction
rotation:	The rotation angle (in degree)
mirror:	The mirror flag (at x axis)

This constructor is provided to construct a matrix similar to the complex transformation. This constructor is called 'newc' to distinguish it from the constructors taking matrix coefficients ('c' is for composite). The order of execution of the operations is mirror, magnification, rotation (as for complex transformations).

(2) Signature: *[static]* new IMatrix2d ptr **newc** (double shear, double mx, double my, double rotation, bool mirror)

Description: Create a new Matrix2d representing a shear, anisotropic magnification, rotation and mirroring

shear:	The shear angle
mx:	The magnification in x direction
my:	The magnification in y direction
rotation:	The rotation angle (in degree)
mirror:	The mirror flag (at x axis)

The order of execution of the operations is mirror, magnification, shear and rotation. This constructor is called 'newc' to distinguish it from the constructor taking the four matrix coefficients ('c' is for composite).

shear_angle

Signature: *[const]* double **shear_angle**

Description: Returns the magnitude of the shear component of this matrix.

Returns:	The shear angle in degree.

The matrix is decomposed into basic transformations assuming an execution order of mirroring at the x axis, rotation, magnification and shear. The shear basic transformation will tilt the x axis towards the y axis and vice versa. The shear angle gives the tilt angle of the axes towards the other one. The possible range for this angle is -45 to 45 degree.

to_s

Signature: *[const]* string **to_s**

Description: Convert the matrix to a string.

Returns:	The string representing this matrix

Python specific notes:

This method is also available as 'str(object)'.

trans

Signature: *[const]* Point **trans** (const Point p)

Description: Transforms a point with this matrix.

p:	The point to transform.
Returns:	The transformed point

Python specific notes:
This method also implements '__rmul__'.

4.67. API reference - Class Matrix3d

Notation used in Ruby API documentation

Module: db

Description: A 3d matrix object used mainly for representing rotation, shear, displacement and perspective transformations.

This object represents a 3x3 matrix. This matrix is used to implement generic geometrical transformations in the 2d space mainly. It can be decomposed into basic transformations: mirroring, rotation, shear, displacement and perspective distortion. In that case, the assumed execution order of the basic transformations is mirroring at the x axis, rotation, magnification, shear, displacement and perspective distortion.

This class was introduced in version 0.22.

Public constructors

new Matrix3d ptr	**new**		Create a new Matrix3d representing a unit transformation
new Matrix3d ptr	**new**	(double m)	Create a new Matrix3d representing a magnification
new Matrix3d ptr	**new**	(const DCplxTrans t)	Create a new Matrix3d from the given complex transformation@param t The transformation from which to create the matrix
new Matrix3d ptr	**new**	(double m11, double m12, double m21, double m22)	Create a new Matrix3d from the four coefficients of a Matrix2d
new Matrix3d ptr	**new**	(double m11, double m12, double m21, double m22, double dx, double dy)	Create a new Matrix3d from the four coefficients of a Matrix2d plus a displacement
new Matrix3d ptr	**new**	(double m11, double m12, double m13, double m21, double m22, double m23, double m31, double m32, double m33)	Create a new Matrix3d from the nine matrix coefficients

Public methods

[const]	Matrix3d	*	(const Matrix3d m)	Product of two matrices.
[const]	DPoint	*	(const DPoint p)	Transforms a point with this matrix.
[const]	DVector	*	(const DVector v)	Transforms a vector with this matrix.

[const]	DEdge	*****	(const DEdge e)	Transforms an edge with this matrix.
[const]	DBox	*****	(const DBox box)	Transforms a box with this matrix.
[const]	DSimplePolygon	*****	(const DSimplePolygon p)	Transforms a simple polygon with this matrix.
[const]	DPolygon	*****	(const DPolygon p)	Transforms a polygon with this matrix.
[const]	Matrix3d	**+**	(const Matrix3d m)	Sum of two matrices.
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**adjust**	(DPoint[] landmarks_before, DPoint[] landmarks_after, int flags, int fixed_point)	Adjust a 3d matrix to match the given set of landmarks
[const]	double	**angle**		Returns the rotation angle of the rotation component of this matrix.
	void	**assign**	(const Matrix3d other)	Assigns another object to self
[const]	DCplxTrans	**cplx_trans**		Converts this matrix to a complex transformation (if possible).
[const]	DVector	**disp**		Returns the displacement vector of this transformation.
[const]	new Matrix3d ptr	**dup**		Creates a copy of self
[const]	Matrix3d	**inverted**		The inverse of this matrix.
[const]	bool	**is_mirror?**		Returns the mirror flag of this matrix.
[const]	double	**m**	(int i, int j)	Gets the m coefficient with the given index.
[const]	double	**mag_x**		Returns the x magnification of the magnification component of this matrix.

[const]	double	**mag_y**		Returns the y magnification of the magnification component of this matrix.
[const]	double	**shear_angle**		Returns the magnitude of the shear component of this matrix.
[const]	string	**to_s**		Convert the matrix to a string.
[const]	DPoint	**trans**	(const DPoint p)	Transforms a point with this matrix.
[const]	double	**tx**	(double z)	Returns the perspective tilt angle tx.
[const]	double	**ty**	(double z)	Returns the perspective tilt angle ty.

Public static methods and constants

int	**AdjustAll**		Mode for adjust: currently equivalent to adjust_perspective
int	**AdjustDisplacement**		Mode for adjust: adjust displacement only
int	**AdjustMagnification**		Mode for adjust: adjust rotation, mirror option and magnification
int	**AdjustNone**		Mode for adjust: adjust nothing
int	**AdjustPerspective**		Mode for adjust: adjust whole matrix including perspective transformation
int	**AdjustRotation**		Mode for adjust: adjust rotation only
int	**AdjustRotationMirror**		Mode for adjust: adjust rotation and mirror option
int	**AdjustShear**		Mode for adjust: adjust rotation, mirror option, magnification and shear
new Matrix3d ptr	**newc**	(double mag, double rotation, bool mirrx)	Create a new Matrix3d representing a isotropic magnification, rotation and mirroring
new Matrix3d ptr	**newc**	(double shear, double mx, double my, double rotation, bool mirrx)	Create a new Matrix3d representing a shear, anisotropic magnification, rotation and mirroring
new Matrix3d ptr	**newc**	(const DVector u, double shear, double mx, double my, double rotation, bool mirrx)	Create a new Matrix3d representing a displacement, shear, anisotropic magnification, rotation and mirroring
new Matrix3d ptr	**newc**	(double tx, double ty, double z, const DVector u, double shear,	Create a new Matrix3d representing a perspective distortion, displacement, shear, anisotropic magnification, rotation and mirroring

double mx,
double my,
double rotation,
bool mirrx)

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

*****

(1) Signature: *[const]* Matrix3d ***** (const Matrix3d m)

Description: Product of two matrices.

m: The other matrix.

Returns: The matrix product self*m

Python specific notes:
This method also implements '__rmul__'.

(2) Signature: *[const]* DPoint ***** (const DPoint p)

Description: Transforms a point with this matrix.

p: The point to transform.

Returns: The transformed point

Python specific notes:
This method also implements '__rmul__'.

(3) Signature: *[const]* DVector ***** (const DVector v)

Description: Transforms a vector with this matrix.

v: The vector to transform.

Returns: The transformed vector

Python specific notes:
This method also implements '__rmul__'.

(4) Signature: *[const]* DEdge ***** (const DEdge e)

Description: Transforms an edge with this matrix.

e: The edge to transform.

Returns: The transformed edge

Python specific notes:
This method also implements '__rmul__'.

(5) Signature: *[const]* DBox ***** (const DBox box)

Description: Transforms a box with this matrix.

box: The box to transform.

Returns: The transformed box

Please note that the box remains a box, even though the matrix supports shear and rotation. The returned box will be the bounding box of the sheared and rotated rectangle.

Python specific notes:
This method also implements '__rmul__'.

(6) Signature: *[const]* DSimplePolygon ***** (const DSimplePolygon p)

Description: Transforms a simple polygon with this matrix.

p: The simple polygon to transform.

Returns: The transformed simple polygon

Python specific notes:
This method also implements '__rmul__'.

(7) Signature: *[const]* DPolygon ***** (const DPolygon p)

Description: Transforms a polygon with this matrix.

p: The polygon to transform.

Returns: The transformed polygon

Python specific notes:
This method also implements '__rmul__'.

+

Signature: *[const]* Matrix3d **+** (const Matrix3d m)

Description: Sum of two matrices.

m: The other matrix.

Returns: The (element-wise) sum of self+m

AdjustAll

Signature: *[static]* int **AdjustAll**

Description: Mode for adjust: currently equivalent to adjust_perspective

Python specific notes:
The object exposes a readable attribute 'AdjustAll'. This is the getter.

AdjustDisplacement

Signature: *[static]* int **AdjustDisplacement**

Description: Mode for adjust: adjust displacement only

Python specific notes:
The object exposes a readable attribute 'AdjustDisplacement'. This is the getter.

AdjustMagnification

Signature: *[static]* int **AdjustMagnification**

Description: Mode for adjust: adjust rotation, mirror option and magnification

Python specific notes:
The object exposes a readable attribute 'AdjustMagnification'. This is the getter.

AdjustNone

Signature: *[static]* int **AdjustNone**

Description: Mode for adjust: adjust nothing

Python specific notes:

	The object exposes a readable attribute 'AdjustNone'. This is the getter.
AdjustPerspective	**Signature**: *[static]* int **AdjustPerspective** **Description**: Mode for adjust: adjust whole matrix including perspective transformation **Python specific notes:** The object exposes a readable attribute 'AdjustPerspective'. This is the getter.
AdjustRotation	**Signature**: *[static]* int **AdjustRotation** **Description**: Mode for adjust: adjust rotation only **Python specific notes:** The object exposes a readable attribute 'AdjustRotation'. This is the getter.
AdjustRotationMirror	**Signature**: *[static]* int **AdjustRotationMirror** **Description**: Mode for adjust: adjust rotation and mirror option **Python specific notes:** The object exposes a readable attribute 'AdjustRotationMirror'. This is the getter.
AdjustShear	**Signature**: *[static]* int **AdjustShear** **Description**: Mode for adjust: adjust rotation, mirror option, magnification and shear **Python specific notes:** The object exposes a readable attribute 'AdjustShear'. This is the getter.
_create	**Signature**: void **_create** **Description**: Ensures the C++ object is created Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
_destroy	**Signature**: void **_destroy** **Description**: Explicitly destroys the object Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
_destroyed?	**Signature**: *[const]* bool **_destroyed?** **Description**: Returns a value indicating whether the object was already destroyed This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
_is_const_object?	**Signature**: *[const]* bool **_is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference This method returns true, if self is a const reference. In that case, only const methods may be called on self.
_manage	**Signature**: void **_manage** **Description**: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

adjust

Signature: void **adjust** (DPoint[] landmarks_before, DPoint[] landmarks_after, int flags, int fixed_point)

Description: Adjust a 3d matrix to match the given set of landmarks

landmarks_before:	The points before the transformation.
landmarks_after:	The points after the transformation.
mode:	Selects the adjustment mode. Must be one of the Adjust... constants.
fixed_point:	The index of the fixed point (one that is definitely mapped to the target) or -1 if there is none

This function tries to adjust the matrix such, that either the matrix is changed as little as possible (if few landmarks are given) or that the "after" landmarks will match as close as possible to the "before" landmarks (if the problem is overdetermined).

angle

Signature: *[const]* double **angle**

Description: Returns the rotation angle of the rotation component of this matrix.

Returns:	The angle in degree.

See the description of this class for details about the basic transformations.

assign

Signature: void **assign** (const Matrix3d other)

Description: Assigns another object to self

cplx_trans

Signature: *[const]* DCplxTrans **cplx_trans**

Description: Converts this matrix to a complex transformation (if possible).

Returns:	The complex transformation.

This method is successful only if the matrix does not contain shear or perspective distortion components and the magnification must be isotropic.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

disp

Signature: *[const]* DVector **disp**

Description: Returns the displacement vector of this transformation.

Returns: The displacement vector.

Starting with version 0.25 this method returns a vector type instead of a point.

dup

Signature: *[const]* new Matrix3d ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

inverted

Signature: *[const]* Matrix3d **inverted**

Description: The inverse of this matrix.

Returns: The inverse of this matrix

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_mirror?

Signature: *[const]* bool **is_mirror?**

Description: Returns the mirror flag of this matrix.

Returns: True if this matrix has a mirror component.

See the description of this class for details about the basic transformations.

m

Signature: *[const]* double **m** (int i, int j)

Description: Gets the m coefficient with the given index.

Returns: The coefficient [i,j]

mag_x

Signature: *[const]* double **mag_x**

Description: Returns the x magnification of the magnification component of this matrix.

Returns: The magnification factor.

mag_y

Signature: *[const]* double **mag_y**

Description: Returns the y magnification of the magnification component of this matrix.

Returns: The magnification factor.

new

(1) Signature: *[static]* new Matrix3d ptr **new**

Description: Create a new Matrix3d representing a unit transformation

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new Matrix3d ptr **new** (double m)

Description: Create a new Matrix3d representing a magnification

m: The magnification

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new Matrix3d ptr **new** (const DCplxTrans t)

Description: Create a new Matrix3d from the given complex transformation@param t The transformation from which to create the matrix

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new Matrix3d ptr **new** (double m11, double m12, double m21, double m22)

Description: Create a new Matrix3d from the four coefficients of a Matrix2d

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new Matrix3d ptr **new** (double m11, double m12, double m21, double m22, double dx, double dy)

Description: Create a new Matrix3d from the four coefficients of a Matrix2d plus a displacement

Python specific notes:
This method is the default initializer of the object.

(6) Signature: *[static]* new Matrix3d ptr **new** (double m11, double m12, double m13, double m21, double m22, double m23, double m31, double m32, double m33)

Description: Create a new Matrix3d from the nine matrix coefficients

Python specific notes:
This method is the default initializer of the object.

newc

(1) Signature: *[static]* new Matrix3d ptr **newc** (double mag, double rotation, bool mirrx)

Description: Create a new Matrix3d representing a isotropic magnification, rotation and mirroring

mag:	The magnification
rotation:	The rotation angle (in degree)
mirrx:	The mirror flag (at x axis)

The order of execution of the operations is mirror, magnification and rotation. This constructor is called 'newc' to distinguish it from the constructors taking coefficients ('c' is for composite).

(2) Signature: *[static]* new Matrix3d ptr **newc** (double shear, double mx, double my, double rotation, bool mirrx)

Description: Create a new Matrix3d representing a shear, anisotropic magnification, rotation and mirroring

shear:	The shear angle
mx:	The magnification in x direction
mx:	The magnification in y direction
rotation:	The rotation angle (in degree)
mirrx:	The mirror flag (at x axis)

The order of execution of the operations is mirror, magnification, rotation and shear. This constructor is called 'newc' to distinguish it from the constructor taking the four matrix coefficients ('c' is for composite).

(3) Signature: *[static]* new Matrix3d ptr **newc** (const DVector u, double shear, double mx, double my, double rotation, bool mirrx)

Description: Create a new Matrix3d representing a displacement, shear, anisotropic magnification, rotation and mirroring

u:	The displacement
shear:	The shear angle
mx:	The magnification in x direction
mx:	The magnification in y direction
rotation:	The rotation angle (in degree)
mirrx:	The mirror flag (at x axis)

The order of execution of the operations is mirror, magnification, rotation, shear and displacement. This constructor is called 'newc' to distinguish it from the constructor taking the four matrix coefficients ('c' is for composite).

Starting with version 0.25 the displacement is of vector type.

(4) Signature: *[static]* new Matrix3d ptr **newc** (double tx, double ty, double z, const DVector u, double shear, double mx, double my, double rotation, bool mirrx)

Description: Create a new Matrix3d representing a perspective distortion, displacement, shear, anisotropic magnification, rotation and mirroring

tx:	The perspective tilt angle x (around the y axis)
ty:	The perspective tilt angle y (around the x axis)
z:	The observer distance at which the tilt angles are given
u:	The displacement
shear:	The shear angle
mx:	The magnification in x direction
mx:	The magnification in y direction

rotation: The rotation angle (in degree)

mirrx: The mirror flag (at x axis)

The order of execution of the operations is mirror, magnification, rotation, shear, perspective distortion and displacement. This constructor is called 'newc' to distinguish it from the constructor taking the four matrix coefficients ('c' is for composite).

The tx and ty parameters represent the perspective distortion. They denote a tilt of the xy plane around the y axis (tx) or the x axis (ty) in degree. The same effect is achieved for different tilt angles for different observer distances. Hence, the observer distance must be given at which the tilt angles are given. If the magnitude of the tilt angle is not important, z can be set to 1.

Starting with version 0.25 the displacement is of vector type.

shear_angle

Signature: *[const]* double **shear_angle**

Description: Returns the magnitude of the shear component of this matrix.

Returns: The shear angle in degree.

The shear basic transformation will tilt the x axis towards the y axis and vice versa. The shear angle gives the tilt angle of the axes towards the other one. The possible range for this angle is -45 to 45 degree.See the description of this class for details about the basic transformations.

to_s

Signature: *[const]* string **to_s**

Description: Convert the matrix to a string.

Returns: The string representing this matrix

Python specific notes:
This method is also available as 'str(object)'.

trans

Signature: *[const]* DPoint **trans** (const DPoint p)

Description: Transforms a point with this matrix.

p: The point to transform.

Returns: The transformed point

Python specific notes:
This method also implements '__rmul__'.

tx

Signature: *[const]* double **tx** (double z)

Description: Returns the perspective tilt angle tx.

z: The observer distance at which the tilt angle is computed.

Returns: The tilt angle tx.

The tx and ty parameters represent the perspective distortion. They denote a tilt of the xy plane around the y axis (tx) or the x axis (ty) in degree. The same effect is achieved for different tilt angles at different observer distances. Hence, the observer distance must be specified at which the tilt angle is computed. If the magnitude of the tilt angle is not important, z can be set to 1.

ty

Signature: *[const]* double **ty** (double z)

Description: Returns the perspective tilt angle ty.

z: The observer distance at which the tilt angle is computed.

Returns: The tilt angle ty.

The tx and ty parameters represent the perspective distortion. They denote a tilt of the xy plane around the y axis (tx) or the x axis (ty) in degree. The same effect is achieved for different tilt angles

at different observer distances. Hence, the observer distance must be specified at which the tilt angle is computed. If the magnitude of the tilt angle is not important, z can be set to 1.

4.68. API reference - Class IMatrix3d

Notation used in Ruby API documentation

Module: db

Description: A 3d matrix object used mainly for representing rotation, shear, displacement and perspective transformations (integer coordinate version).

This object represents a 3x3 matrix. This matrix is used to implement generic geometrical transformations in the 2d space mainly. It can be decomposed into basic transformations: mirroring, rotation, shear, displacement and perspective distortion. In that case, the assumed execution order of the basic transformations is mirroring at the x axis, rotation, magnification, shear, displacement and perspective distortion.

The integer variant was introduced in version 0.27.

Public constructors

new IMatrix3d ptr	**new**		Create a new Matrix3d representing a unit transformation
new IMatrix3d ptr	**new**	(double m)	Create a new Matrix3d representing a magnification
new IMatrix3d ptr	**new**	(const ICplxTrans t)	Create a new Matrix3d from the given complex transformation@param t The transformation from which to create the matrix
new IMatrix3d ptr	**new**	(double m11, double m12, double m21, double m22)	Create a new Matrix3d from the four coefficients of a Matrix2d
new IMatrix3d ptr	**new**	(double m11, double m12, double m21, double m22, double dx, double dy)	Create a new Matrix3d from the four coefficients of a Matrix2d plus a displacement
new IMatrix3d ptr	**new**	(double m11, double m12, double m13, double m21, double m22, double m23, double m31, double m32, double m33)	Create a new Matrix3d from the nine matrix coefficients

Public methods

[const]	IMatrix3d	*	(const IMatrix3d m)	Product of two matrices.
[const]	Point	*	(const Point p)	Transforms a point with this matrix.
[const]	Vector	*	(const Vector v)	Transforms a vector with this matrix.

[const]	Edge	*****	(const Edge e)	Transforms an edge with this matrix.
[const]	Box	*****	(const Box box)	Transforms a box with this matrix.
[const]	SimplePolygon	*****	(const SimplePolygon p)	Transforms a simple polygon with this matrix.
[const]	Polygon	*****	(const Polygon p)	Transforms a polygon with this matrix.
[const]	IMatrix3d	**+**	(const IMatrix3d m)	Sum of two matrices.
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	double	**angle**		Returns the rotation angle of the rotation component of this matrix.
	void	**assign**	(const IMatrix3d other)	Assigns another object to self
[const]	DCplxTrans	**cplx_trans**		Converts this matrix to a complex transformation (if possible).
[const]	Vector	**disp**		Returns the displacement vector of this transformation.
[const]	new IMatrix3d ptr	**dup**		Creates a copy of self
[const]	IMatrix3d	**inverted**		The inverse of this matrix.
[const]	bool	**is_mirror?**		Returns the mirror flag of this matrix.
[const]	double	**m**	(int i, int j)	Gets the m coefficient with the given index.
[const]	double	**mag_x**		Returns the x magnification of the magnification component of this matrix.
[const]	double	**mag_y**		Returns the y magnification of the magnification component of this matrix.

[const]	double	**shear_angle**		Returns the magnitude of the shear component of this matrix.
[const]	string	**to_s**		Convert the matrix to a string.
[const]	Point	**trans**	(const Point p)	Transforms a point with this matrix.
[const]	double	**tx**	(double z)	Returns the perspective tilt angle tx.
[const]	double	**ty**	(double z)	Returns the perspective tilt angle ty.

Public static methods and constants

new IMatrix3d ptr	**newc**	(double mag, double rotation, bool mirrx)	Create a new Matrix3d representing a isotropic magnification, rotation and mirroring
new IMatrix3d ptr	**newc**	(double shear, double mx, double my, double rotation, bool mirrx)	Create a new Matrix3d representing a shear, anisotropic magnification, rotation and mirroring
new IMatrix3d ptr	**newc**	(const Vector u, double shear, double mx, double my, double rotation, bool mirrx)	Create a new Matrix3d representing a displacement, shear, anisotropic magnification, rotation and mirroring
new IMatrix3d ptr	**newc**	(double tx, double ty, double z, const Vector u, double shear, double mx, double my, double rotation, bool mirrx)	Create a new Matrix3d representing a perspective distortion, displacement, shear, anisotropic magnification, rotation and mirroring

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

(1) Signature: *[const]* IMatrix3d ***** (const IMatrix3d m)

*****

Description: Product of two matrices.

m: The other matrix.

Returns: The matrix product self*m

Python specific notes:
This method also implements '__rmul__'.

(2) Signature: *[const]* Point ***** (const Point p)

Description: Transforms a point with this matrix.

p: The point to transform.

Returns: The transformed point

Python specific notes:
This method also implements '__rmul__'.

(3) Signature: *[const]* Vector ***** (const Vector v)

Description: Transforms a vector with this matrix.

v: The vector to transform.

Returns: The transformed vector

Python specific notes:
This method also implements '__rmul__'.

(4) Signature: *[const]* Edge ***** (const Edge e)

Description: Transforms an edge with this matrix.

e: The edge to transform.

Returns: The transformed edge

Python specific notes:
This method also implements '__rmul__'.

(5) Signature: *[const]* Box ***** (const Box box)

Description: Transforms a box with this matrix.

box: The box to transform.

Returns: The transformed box

Please note that the box remains a box, even though the matrix supports shear and rotation. The returned box will be the bounding box of the sheared and rotated rectangle.

Python specific notes:
This method also implements '__rmul__'.

(6) Signature: *[const]* SimplePolygon ***** (const SimplePolygon p)

Description: Transforms a simple polygon with this matrix.

p: The simple polygon to transform.

Returns: The transformed simple polygon

Python specific notes:
This method also implements '__rmul__'.

(7) Signature: *[const]* Polygon ***** (const Polygon p)

Description: Transforms a polygon with this matrix.

p: The polygon to transform.

Returns: The transformed polygon

Python specific notes:
This method also implements '__rmul__'.

+

Signature: *[const]* IMatrix3d **+** (const IMatrix3d m)

Description: Sum of two matrices.

m: The other matrix.

Returns: The (element-wise) sum of self+m

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

angle

Signature: *[const]* double **angle**

Description: Returns the rotation angle of the rotation component of this matrix.

Returns: The angle in degree.

See the description of this class for details about the basic transformations.

assign

Signature: void **assign** (const IMatrix3d other)

Description: Assigns another object to self

cplx_trans

Signature: *[const]* DCplxTrans **cplx_trans**

Description: Converts this matrix to a complex transformation (if possible).

Returns: The complex transformation.

This method is successful only if the matrix does not contain shear or perspective distortion components and the magnification must be isotropic.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

disp

Signature: *[const]* Vector **disp**

Description: Returns the displacement vector of this transformation.

Returns: The displacement vector.

Starting with version 0.25 this method returns a vector type instead of a point.

dup

Signature: *[const]* new IMatrix3d ptr **dup**

Description: Creates a copy of self

Python specific notes:

This method also implements '__copy__' and '__deepcopy__'.

inverted

Signature: *[const]* IMatrix3d **inverted**

Description: The inverse of this matrix.

Returns: The inverse of this matrix

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_mirror?

Signature: *[const]* bool **is_mirror?**

Description: Returns the mirror flag of this matrix.

Returns: True if this matrix has a mirror component.

See the description of this class for details about the basic transformations.

m

Signature: *[const]* double **m** (int i, int j)

Description: Gets the m coefficient with the given index.

Returns: The coefficient [i,j]

mag_x

Signature: *[const]* double **mag_x**

Description: Returns the x magnification of the magnification component of this matrix.

Returns: The magnification factor.

mag_y

Signature: *[const]* double **mag_y**

Description: Returns the y magnification of the magnification component of this matrix.

Returns: The magnification factor.

new

(1) Signature: *[static]* new IMatrix3d ptr **new**

Description: Create a new Matrix3d representing a unit transformation

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new IMatrix3d ptr **new** (double m)

Description: Create a new Matrix3d representing a magnification

m: The magnification

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new IMatrix3d ptr **new** (const ICplxTrans t)

Description: Create a new Matrix3d from the given complex transformation@param t The transformation from which to create the matrix

Python specific notes:

This method is the default initializer of the object.

(4) Signature: *[static]* new IMatrix3d ptr **new** (double m11, double m12, double m21, double m22)

Description: Create a new Matrix3d from the four coefficients of a Matrix2d

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new IMatrix3d ptr **new** (double m11, double m12, double m21, double m22, double dx, double dy)

Description: Create a new Matrix3d from the four coefficients of a Matrix2d plus a displacement

Python specific notes:
This method is the default initializer of the object.

(6) Signature: *[static]* new IMatrix3d ptr **new** (double m11, double m12, double m13, double m21, double m22, double m23, double m31, double m32, double m33)

Description: Create a new Matrix3d from the nine matrix coefficients

Python specific notes:
This method is the default initializer of the object.

newc

(1) Signature: *[static]* new IMatrix3d ptr **newc** (double mag, double rotation, bool mirrx)

Description: Create a new Matrix3d representing a isotropic magnification, rotation and mirroring

mag:	The magnification
rotation:	The rotation angle (in degree)
mirrx:	The mirror flag (at x axis)

The order of execution of the operations is mirror, magnification and rotation. This constructor is called 'newc' to distinguish it from the constructors taking coefficients ('c' is for composite).

(2) Signature: *[static]* new IMatrix3d ptr **newc** (double shear, double mx, double my, double rotation, bool mirrx)

Description: Create a new Matrix3d representing a shear, anisotropic magnification, rotation and mirroring

shear:	The shear angle
mx:	The magnification in x direction
mx:	The magnification in y direction
rotation:	The rotation angle (in degree)
mirrx:	The mirror flag (at x axis)

The order of execution of the operations is mirror, magnification, rotation and shear. This constructor is called 'newc' to distinguish it from the constructor taking the four matrix coefficients ('c' is for composite).

(3) Signature: *[static]* new IMatrix3d ptr **newc** (const Vector u, double shear, double mx, double my, double rotation, bool mirrx)

Description: Create a new Matrix3d representing a displacement, shear, anisotropic magnification, rotation and mirroring

u:	The displacement
shear:	The shear angle

mx:	The magnification in x direction
mx:	The magnification in y direction
rotation:	The rotation angle (in degree)
mirrx:	The mirror flag (at x axis)

The order of execution of the operations is mirror, magnification, rotation, shear and displacement. This constructor is called 'newc' to distinguish it from the constructor taking the four matrix coefficients ('c' is for composite).

Starting with version 0.25 the displacement is of vector type.

(4) Signature: *[static]* new IMatrix3d ptr **newc** (double tx, double ty, double z, const Vector u, double shear, double mx, double my, double rotation, bool mirrx)

Description: Create a new Matrix3d representing a perspective distortion, displacement, shear, anisotropic magnification, rotation and mirroring

tx:	The perspective tilt angle x (around the y axis)
ty:	The perspective tilt angle y (around the x axis)
z:	The observer distance at which the tilt angles are given
u:	The displacement
shear:	The shear angle
mx:	The magnification in x direction
mx:	The magnification in y direction
rotation:	The rotation angle (in degree)
mirrx:	The mirror flag (at x axis)

The order of execution of the operations is mirror, magnification, rotation, shear, perspective distortion and displacement. This constructor is called 'newc' to distinguish it from the constructor taking the four matrix coefficients ('c' is for composite).

The tx and ty parameters represent the perspective distortion. They denote a tilt of the xy plane around the y axis (tx) or the x axis (ty) in degree. The same effect is achieved for different tilt angles for different observer distances. Hence, the observer distance must be given at which the tilt angles are given. If the magnitude of the tilt angle is not important, z can be set to 1.

Starting with version 0.25 the displacement is of vector type.

shear_angle

Signature: *[const]* double **shear_angle**

Description: Returns the magnitude of the shear component of this matrix.

Returns:	The shear angle in degree.

The shear basic transformation will tilt the x axis towards the y axis and vice versa. The shear angle gives the tilt angle of the axes towards the other one. The possible range for this angle is -45 to 45 degree.See the description of this class for details about the basic transformations.

to_s

Signature: *[const]* string **to_s**

Description: Convert the matrix to a string.

Returns:	The string representing this matrix

Python specific notes:
This method is also available as 'str(object)'.

trans

Signature: *[const]* Point **trans** (const Point p)

Description: Transforms a point with this matrix.

p: The point to transform.

Returns: The transformed point

Python specific notes:
This method also implements '__rmul__'.

tx

Signature: *[const]* double **tx** (double z)

Description: Returns the perspective tilt angle tx.

z: The observer distance at which the tilt angle is computed.

Returns: The tilt angle tx.

The tx and ty parameters represent the perspective distortion. They denote a tilt of the xy plane around the y axis (tx) or the x axis (ty) in degree. The same effect is achieved for different tilt angles at different observer distances. Hence, the observer distance must be specified at which the tilt angle is computed. If the magnitude of the tilt angle is not important, z can be set to 1.

ty

Signature: *[const]* double **ty** (double z)

Description: Returns the perspective tilt angle ty.

z: The observer distance at which the tilt angle is computed.

Returns: The tilt angle ty.

The tx and ty parameters represent the perspective distortion. They denote a tilt of the xy plane around the y axis (tx) or the x axis (ty) in degree. The same effect is achieved for different tilt angles at different observer distances. Hence, the observer distance must be specified at which the tilt angle is computed. If the magnitude of the tilt angle is not important, z can be set to 1.

4.69. API reference - Class LayoutMetaInfo

Notation used in Ruby API documentation

Module: db

Description: A piece of layout meta information

Layout meta information is basically additional data that can be attached to a layout. Layout readers may generate meta information and some writers will add layout information to the layout object. Some writers will also read meta information to determine certain attributes.

Multiple layout meta information objects can be attached to one layout using Layout#add_meta_info. Meta information is identified by a unique name and carries a string value plus an optional description string. The description string is for information only and is not evaluated by code.

Meta information can be attached to the layout object and to cells. It is similar to user properties. The differences are:

- Meta information is stored differently in GDS and OASIS files using the context information added by KLayout to annotated PCell or library cells too. Hence meta information does not pollute the standard user properties space.
- The value of meta information can be complex serializable types such as lists, hashes and elementary objects such as Box or DBox. Scalar types include floats and booleans.
- Meta information keys are strings and are supported also for GDS which only accepts integer number keys for user properties.

Elementary (serializable) objects are: Box, DBox, Edge, DEdge, EdgePair, DEdgePair, EdgePairs, Edges, LayerProperties, Matrix2d, Matrix3d, Path, DPath, Point, DPoint, Polygon, DPolygon, SimplePolygon, DSimplePolygon, Region, Text, DText, Texts, Trans, DTrans, CplxTrans, ICplxTrans, DCplxTrans, VCplxTrans, Vector, DVector (list may not be complete).

KLayout itself also generates meta information with specific keys. For disambiguation, namespaces can be established by prefixing the key strings with some unique identifier in XML fashion, like a domain name - e.g. 'example.com:key'.

Note: only meta information marked with is_persisted? == true is stored in GDS or OASIS files. This is not the default setting, so you need to explicitly set that flag.

See also Layout#each_meta_info, Layout#meta_info_value, Layout#meta_info and Layout#remove_meta_info as well as the corresponding Cell methods.

An example of how to attach persisted meta information to a cell is here:

```
ly = RBA::Layout::new
c1 = ly.create_cell("C1")

mi = RBA::LayoutMetaInfo::new("the-answer", 42.0)
mi.persisted = true
c1.add_meta_info(mi)

# will now hold this piece of meta information attached to cell 'C1':
ly.write("to.gds")
```

This class has been introduced in version 0.25 and was extended in version 0.28.8.

Public constructors

new LayoutMetaInfo ptr	**new**	(string name, variant value, string description = , bool persisted = false)	Creates a layout meta info object

Public methods

void	**_create**	Ensures the C++ object is created

	void	_destroy		Explicitly destroys the object
[const]	bool	_destroyed?		Returns a value indicating whether the object was already destroyed
[const]	bool	_is_const_object?		Returns a value indicating whether the reference is a const reference
	void	_manage		Marks the object as managed by the script side.
	void	_unmanage		Marks the object as no longer owned by the script side.
	void	assign	(const LayoutMetaInf other)	Assigns another object to self
[const]	string	description		Gets the description of the layout meta info object
	void	description=	(string description)	Sets the description of the layout meta info object
[const]	new LayoutMetaInfo ptr	dup		Creates a copy of self
[const]	bool	is_persisted?		Gets a value indicating whether the meta information will be persisted
[const]	string	name		Gets the name of the layout meta info object
	void	name=	(string name)	Sets the name of the layout meta info object
	void	persisted=	(bool flag)	Sets a value indicating whether the meta information will be persisted
[const]	variant	value		Gets the value of the layout meta info object
	void	value=	(variant value)	Sets the value of the layout meta info object

Deprecated methods (protected, public, static, non-static and constructors)

	void	create	Use of this method is deprecated. Use _create instead
	void	destroy	Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	is_const_object?	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create	**Signature**: void **_create** **Description**: Ensures the C++ object is created Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
_destroy	**Signature**: void **_destroy** **Description**: Explicitly destroys the object Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
_destroyed?	**Signature**: *[const]* bool **_destroyed?** **Description**: Returns a value indicating whether the object was already destroyed This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
_is_const_object?	**Signature**: *[const]* bool **_is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference This method returns true, if self is a const reference. In that case, only const methods may be called on self.
_manage	**Signature**: void **_manage** **Description**: Marks the object as managed by the script side. After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required. Usually it's not required to call this method. It has been introduced in version 0.24.
_unmanage	**Signature**: void **_unmanage** **Description**: Marks the object as no longer owned by the script side. Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.
assign	**Signature**: void **assign** (const LayoutMetaInfo other) **Description**: Assigns another object to self
create	**Signature**: void **create** **Description**: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

description

Signature: *[const]* string **description**

Description: Gets the description of the layout meta info object

Python specific notes:
The object exposes a readable attribute 'description'. This is the getter.

description=

Signature: void **description=** (string description)

Description: Sets the description of the layout meta info object

Python specific notes:
The object exposes a writable attribute 'description'. This is the setter.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new LayoutMetaInfo ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_persisted?

Signature: *[const]* bool **is_persisted?**

Description: Gets a value indicating whether the meta information will be persisted

This predicate was introduced in version 0.28.8.

Python specific notes:
The object exposes a readable attribute 'persisted'. This is the getter.

name

Signature: *[const]* string **name**

Description: Gets the name of the layout meta info object

Python specific notes:
The object exposes a readable attribute 'name'. This is the getter.

name=

Signature: void **name=** (string name)

Description: Sets the name of the layout meta info object

Python specific notes:
The object exposes a writable attribute 'name'. This is the setter.

new

Signature: *[static]* new LayoutMetaInfo ptr **new** (string name, variant value, string description = , bool persisted = false)

Description: Creates a layout meta info object

name:	The name
value:	The value
description:	An optional description text
persisted:	If true, the meta information will be persisted in some file formats, like GDS2

The 'persisted' attribute has been introduced in version 0.28.8.

Python specific notes:
This method is the default initializer of the object.

persisted=

Signature: void **persisted=** (bool flag)

Description: Sets a value indicating whether the meta information will be persisted

This predicate was introduced in version 0.28.8.

Python specific notes:
The object exposes a writable attribute 'persisted'. This is the setter.

value

Signature: *[const]* variant **value**

Description: Gets the value of the layout meta info object

Python specific notes:
The object exposes a readable attribute 'value'. This is the getter.

value=

Signature: void **value=** (variant value)

Description: Sets the value of the layout meta info object

Python specific notes:
The object exposes a writable attribute 'value'. This is the setter.

4.70. API reference - Class Path

Notation used in Ruby API documentation

Module: db

Description: A path class

A path consists of an sequence of line segments forming the 'spine' of the path and a width. In addition, the starting point can be drawn back by a certain extent (the 'begin extension') and the end point can be pulled forward somewhat (by the 'end extension').

A path may have round ends for special purposes. In particular, a round-ended path with a single point can represent a circle. Round-ended paths should have being and end extensions equal to half the width. Non-round-ended paths with a single point are allowed but the definition of the resulting shape in not well defined and may differ in other tools.

See The Database API for more details about the database objects.

Public constructors

new Path ptr	**new**	(const DPath dpath)	Creates an integer coordinate path from a floating-point coordinate path
new Path ptr	**new**		Default constructor: creates an empty (invalid) path with width 0
new Path ptr	**new**	(Point[] pts, int width)	Constructor given the points of the path's spine and the width
new Path ptr	**new**	(Point[] pts, int width, int bgn_ext, int end_ext)	Constructor given the points of the path's spine, the width and the extensions
new Path ptr	**new**	(Point[] pts, int width, int bgn_ext, int end_ext, bool round)	Constructor given the points of the path's spine, the width, the extensions and the round end flag

Public methods

[const]	bool	**!=**	(const Path p)	Inequality test
[const]	Path	*****	(double f)	Scaling by some factor
[const]	bool	**<**	(const Path p)	Less operator
[const]	bool	**==**	(const Path p)	Equality test
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference

	void	_manage		Marks the object as managed by the script side.
	void	_unmanage		Marks the object as no longer owned by the script side.
[const]	long	area		Returns the approximate area of the path
	void	assign	(const Path other)	Assigns another object to self
[const]	Box	bbox		Returns the bounding box of the path
[const]	int	bgn_ext		Get the begin extension
	void	bgn_ext=	(int ext)	Set the begin extension
[const]	new Path ptr	dup		Creates a copy of self
[const,iter]	Point	each_point		Get the points that make up the path's spine
[const]	int	end_ext		Get the end extension
	void	end_ext=	(int ext)	Set the end extension
[const]	unsigned long	hash		Computes a hash value
[const]	bool	is_round?		Returns true, if the path has round ends
[const]	unsigned int	length		Returns the length of the path
	Path	move	(const Vector p)	Moves the path.
	Path	move	(int dx, int dy)	Moves the path.
[const]	Path	moved	(const Vector p)	Returns the moved path (does not change self)
[const]	Path	moved	(int dx, int dy)	Returns the moved path (does not change self)
[const]	unsigned long	num_points		Get the number of points
[const]	unsigned long	perimeter		Returns the approximate perimeter of the path
	void	points=	(Point[] p)	Set the points of the path
[const]	Polygon	polygon		Convert the path to a polygon
	void	round=	(bool round_ends_flag)	Set the 'round ends' flag
[const]	Path	round_corners	(double radius, int npoints)	Creates a new path whose corners are interpolated with circular bends

[const]	SimplePolygon	**simple_polygon**		Convert the path to a simple polygon
[const]	DPath	**to_dtype**	(double dbu = 1)	Converts the path to a floating-point coordinate path
[const]	string	**to_s**		Convert to a string
[const]	Path	**transformed**	(const ICplxTrans t)	Transform the path.
[const]	Path	**transformed**	(const Trans t)	Transform the path.
[const]	DPath	**transformed**	(const CplxTrans t)	Transform the path.
[const]	int	**width**		Get the width
	void	**width=**	(int w)	Set the width

Public static methods and constants

new Path ptr	**from_s**	(string s)	Creates an object from a string

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**		Use of this method is deprecated. Use _create instead
	void	**destroy**		Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**		Use of this method is deprecated. Use _destroyed? instead
[static]	new Path ptr	**from_dpath**	(const DPath dpath)	Use of this method is deprecated. Use new instead
[const]	bool	**is_const_object?**		Use of this method is deprecated. Use _is_const_object? instead
[static]	new Path ptr	**new_pw**	(Point[] pts, int width)	Use of this method is deprecated. Use new instead
[static]	new Path ptr	**new_pwx**	(Point[] pts, int width, int bgn_ext, int end_ext)	Use of this method is deprecated. Use new instead
[static]	new Path ptr	**new_pwxr**	(Point[] pts, int width, int bgn_ext, int end_ext, bool round)	Use of this method is deprecated. Use new instead
[const]	unsigned long	**points**		Use of this method is deprecated. Use num_points instead

[const]	DPath	**transformed_cplx**	(const CplxTrans t)	Use of this method is deprecated. Use transformed instead

Detailed description

!=

Signature: *[const]* bool **!=** (const Path p)

Description: Inequality test

p: The object to compare against

*****

Signature: *[const]* Path ***** (double f)

Description: Scaling by some factor

Returns the scaled object. All coordinates are multiplied with the given factor and if necessary rounded.

Python specific notes:
This method also implements '__rmul__'.

<

Signature: *[const]* bool **<** (const Path p)

Description: Less operator

p: The object to compare against

This operator is provided to establish some, not necessarily a certain sorting order

==

Signature: *[const]* bool **==** (const Path p)

Description: Equality test

p: The object to compare against

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

area

Signature: *[const]* long **area**

Description: Returns the approximate area of the path

This method returns the approximate value of the area. It is computed from the length times the width. end extensions are taken into account correctly, but not effects of the corner interpolation. This method was added in version 0.22.

assign

Signature: void **assign** (const Path other)

Description: Assigns another object to self

bbox

Signature: *[const]* Box **bbox**

Description: Returns the bounding box of the path

bgn_ext

Signature: *[const]* int **bgn_ext**

Description: Get the begin extension

Python specific notes:
The object exposes a readable attribute 'bgn_ext'. This is the getter.

bgn_ext=

Signature: void **bgn_ext=** (int ext)

Description: Set the begin extension

Python specific notes:
The object exposes a writable attribute 'bgn_ext'. This is the setter.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new Path ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

each_point

Signature: *[const,iter]* Point **each_point**

Description: Get the points that make up the path's spine

end_ext

Signature: *[const]* int **end_ext**

Description: Get the end extension

Python specific notes:
The object exposes a readable attribute 'end_ext'. This is the getter.

end_ext=

Signature: void **end_ext=** (int ext)

Description: Set the end extension

Python specific notes:
The object exposes a writable attribute 'end_ext'. This is the setter.

from_dpath

Signature: *[static]* new Path ptr **from_dpath** (const DPath dpath)

Description: Creates an integer coordinate path from a floating-point coordinate path

Use of this method is deprecated. Use new instead

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_dpath'.

Python specific notes:
This method is the default initializer of the object.

from_s

Signature: *[static]* new Path ptr **from_s** (string s)

Description: Creates an object from a string

Creates the object from a string representation (as returned by to_s)

This method has been added in version 0.23.

hash

Signature: *[const]* unsigned long **hash**

Description: Computes a hash value

Returns a hash value for the given polygon. This method enables polygons as hash keys.

This method has been introduced in version 0.25.

Python specific notes:
This method is also available as 'hash(object)'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_round?

Signature: *[const]* bool **is_round?**

Description: Returns true, if the path has round ends

Python specific notes:
The object exposes a readable attribute 'round'. This is the getter.

length

Signature: *[const]* unsigned int **length**

Description: Returns the length of the path

the length of the path is determined by summing the lengths of the segments and adding begin and end extensions. For round-ended paths the length of the paths between the tips of the ends.

This method was added in version 0.23.

move

(1) Signature: Path **move** (const Vector p)

Description: Moves the path.

p:	The distance to move the path.
Returns:	The moved path.

Moves the path by the given offset and returns the moved path. The path is overwritten.

(2) Signature: Path **move** (int dx, int dy)

Description: Moves the path.

dx:	The x distance to move the path.
dy:	The y distance to move the path.
Returns:	The moved path.

Moves the path by the given offset and returns the moved path. The path is overwritten.

This version has been added in version 0.23.

moved

(1) Signature: *[const]* Path **moved** (const Vector p)

Description: Returns the moved path (does not change self)

p:	The distance to move the path.
Returns:	The moved path.

Moves the path by the given offset and returns the moved path. The path is not modified.

(2) Signature: *[const]* Path **moved** (int dx, int dy)

Description: Returns the moved path (does not change self)

dx:	The x distance to move the path.
dy:	The y distance to move the path.
Returns:	The moved path.

Moves the path by the given offset and returns the moved path. The path is not modified.

This version has been added in version 0.23.

new

(1) Signature: *[static]* new Path ptr **new** (const DPath dpath)

Description: Creates an integer coordinate path from a floating-point coordinate path

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_dpath'.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new Path ptr **new**

Description: Default constructor: creates an empty (invalid) path with width 0

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new Path ptr **new** (Point[] pts, int width)

Description: Constructor given the points of the path's spine and the width

pts:	The points forming the spine of the path
width:	The width of the path

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new Path ptr **new** (Point[] pts, int width, int bgn_ext, int end_ext)

Description: Constructor given the points of the path's spine, the width and the extensions

pts:	The points forming the spine of the path
width:	The width of the path
bgn_ext:	The begin extension of the path
end_ext:	The end extension of the path

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new Path ptr **new** (Point[] pts, int width, int bgn_ext, int end_ext, bool round)

Description: Constructor given the points of the path's spine, the width, the extensions and the round end flag

pts:	The points forming the spine of the path
width:	The width of the path
bgn_ext:	The begin extension of the path
end_ext:	The end extension of the path

round: If this flag is true, the path will get rounded ends

Python specific notes:
This method is the default initializer of the object.

new_pw

Signature: *[static]* new Path ptr **new_pw** (Point[] pts, int width)

Description: Constructor given the points of the path's spine and the width

pts: The points forming the spine of the path

width: The width of the path

Use of this method is deprecated. Use new instead

Python specific notes:
This method is the default initializer of the object.

new_pwx

Signature: *[static]* new Path ptr **new_pwx** (Point[] pts, int width, int bgn_ext, int end_ext)

Description: Constructor given the points of the path's spine, the width and the extensions

pts: The points forming the spine of the path

width: The width of the path

bgn_ext: The begin extension of the path

end_ext: The end extension of the path

Use of this method is deprecated. Use new instead

Python specific notes:
This method is the default initializer of the object.

new_pwxr

Signature: *[static]* new Path ptr **new_pwxr** (Point[] pts, int width, int bgn_ext, int end_ext, bool round)

Description: Constructor given the points of the path's spine, the width, the extensions and the round end flag

pts: The points forming the spine of the path

width: The width of the path

bgn_ext: The begin extension of the path

end_ext: The end extension of the path

round: If this flag is true, the path will get rounded ends

Use of this method is deprecated. Use new instead

Python specific notes:
This method is the default initializer of the object.

num_points

Signature: *[const]* unsigned long **num_points**

Description: Get the number of points

Python specific notes:
The object exposes a readable attribute 'points'. This is the getter.

perimeter

Signature: *[const]* unsigned long **perimeter**

Description: Returns the approximate perimeter of the path

This method returns the approximate value of the perimeter. It is computed from the length and the width. end extensions are taken into account correctly, but not effects of the corner interpolation. This method was added in version 0.24.4.

points

Signature: *[const]* unsigned long **points**

Description: Get the number of points

Use of this method is deprecated. Use num_points instead

Python specific notes:
The object exposes a readable attribute 'points'. This is the getter.

points=

Signature: void **points=** (Point[] p)

Description: Set the points of the path

p: An array of points to assign to the path's spine

Python specific notes:
The object exposes a writable attribute 'points'. This is the setter.

polygon

Signature: *[const]* Polygon **polygon**

Description: Convert the path to a polygon

The returned polygon is not guaranteed to be non-self overlapping. This may happen if the path overlaps itself or contains very short segments.

round=

Signature: void **round=** (bool round_ends_flag)

Description: Set the 'round ends' flag

A path with round ends show half circles at the ends, instead of square or rectangular ends. Paths with this flag set should use a begin and end extension of half the width (see bgn_ext and end_ext). The interpretation of such paths in other tools may differ otherwise.

Python specific notes:
The object exposes a writable attribute 'round'. This is the setter.

round_corners

Signature: *[const]* Path **round_corners** (double radius, int npoints)

Description: Creates a new path whose corners are interpolated with circular bends

radius: The radius of the bends

npoints: The number of points (per full circle) used for interpolating the bends

This method has been introduced in version 0.25.

simple_polygon

Signature: *[const]* SimplePolygon **simple_polygon**

Description: Convert the path to a simple polygon

The returned polygon is not guaranteed to be non-selfoverlapping. This may happen if the path overlaps itself or contains very short segments.

to_dtype

Signature: *[const]* DPath **to_dtype** (double dbu = 1)

Description: Converts the path to a floating-point coordinate path

The database unit can be specified to translate the integer-coordinate path into a floating-point coordinate path in micron units. The database unit is basically a scaling factor.

This method has been introduced in version 0.25.

to_s

Signature: *[const]* string **to_s**

Description: Convert to a string

Python specific notes:
This method is also available as 'str(object)'.

transformed

(1) Signature: *[const]* Path **transformed** (const ICplxTrans t)

Description: Transform the path.

t: The transformation to apply.

Returns: The transformed path (in this case an integer coordinate path).

Transforms the path with the given complex transformation. Does not modify the path but returns the transformed path.

This method has been introduced in version 0.18.

(2) Signature: *[const]* Path **transformed** (const Trans t)

Description: Transform the path.

t: The transformation to apply.

Returns: The transformed path.

Transforms the path with the given transformation. Does not modify the path but returns the transformed path.

(3) Signature: *[const]* DPath **transformed** (const CplxTrans t)

Description: Transform the path.

t: The transformation to apply.

Returns: The transformed path.

Transforms the path with the given complex transformation. Does not modify the path but returns the transformed path.

transformed_cplx

Signature: *[const]* DPath **transformed_cplx** (const CplxTrans t)

Description: Transform the path.

t: The transformation to apply.

Returns: The transformed path.

Use of this method is deprecated. Use transformed instead

Transforms the path with the given complex transformation. Does not modify the path but returns the transformed path.

width

Signature: *[const]* int **width**

Description: Get the width

Python specific notes:
The object exposes a readable attribute 'width'. This is the getter.

width=

Signature: void **width=** (int w)

Description: Set the width

Python specific notes:
The object exposes a writable attribute 'width'. This is the setter.

4.71. API reference - Class DPath

Notation used in Ruby API documentation

Module: db

Description: A path class

A path consists of an sequence of line segments forming the 'spine' of the path and a width. In addition, the starting point can be drawn back by a certain extent (the 'begin extension') and the end point can be pulled forward somewhat (by the 'end extension').

A path may have round ends for special purposes. In particular, a round-ended path with a single point can represent a circle. Round-ended paths should have being and end extensions equal to half the width. Non-round-ended paths with a single point are allowed but the definition of the resulting shape in not well defined and may differ in other tools.

See The Database API for more details about the database objects.

Public constructors

new DPath ptr	**new**	(const Path path)	Creates a floating-point coordinate path from an integer coordinate path
new DPath ptr	**new**		Default constructor: creates an empty (invalid) path with width 0
new DPath ptr	**new**	(DPoint[] pts, double width)	Constructor given the points of the path's spine and the width
new DPath ptr	**new**	(DPoint[] pts, double width, double bgn_ext, double end_ext)	Constructor given the points of the path's spine, the width and the extensions
new DPath ptr	**new**	(DPoint[] pts, double width, double bgn_ext, double end_ext, bool round)	Constructor given the points of the path's spine, the width, the extensions and the round end flag

Public methods

[const]	bool	**!=**	(const DPath p)	Inequality test
[const]	DPath	*****	(double f)	Scaling by some factor
[const]	bool	**<**	(const DPath p)	Less operator
[const]	bool	**==**	(const DPath p)	Equality test
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference

	void	_manage		Marks the object as managed by the script side.
	void	_unmanage		Marks the object as no longer owned by the script side.
[const]	double	area		Returns the approximate area of the path
	void	assign	(const DPath other)	Assigns another object to self
[const]	DBox	bbox		Returns the bounding box of the path
[const]	double	bgn_ext		Get the begin extension
	void	bgn_ext=	(double ext)	Set the begin extension
[const]	new DPath ptr	dup		Creates a copy of self
[const,iter]	DPoint	each_point		Get the points that make up the path's spine
[const]	double	end_ext		Get the end extension
	void	end_ext=	(double ext)	Set the end extension
[const]	unsigned long	hash		Computes a hash value
[const]	bool	is_round?		Returns true, if the path has round ends
[const]	double	length		Returns the length of the path
	DPath	move	(const DVector p)	Moves the path.
	DPath	move	(double dx, double dy)	Moves the path.
[const]	DPath	moved	(const DVector p)	Returns the moved path (does not change self)
[const]	DPath	moved	(double dx, double dy)	Returns the moved path (does not change self)
[const]	unsigned long	num_points		Get the number of points
[const]	double	perimeter		Returns the approximate perimeter of the path
	void	points=	(DPoint[] p)	Set the points of the path
[const]	DPolygon	polygon		Convert the path to a polygon
	void	round=	(bool round_ends_flag)	Set the 'round ends' flag
[const]	DPath	round_corners	(double radius, int npoints, double accuracy)	Creates a new path whose corners are interpolated with circular bends

[const]	DSimplePolygon	**simple_polygon**		Convert the path to a simple polygon
[const]	Path	**to_itype**	(double dbu = 1)	Converts the path to an integer coordinate path
[const]	string	**to_s**		Convert to a string
[const]	Path	**transformed**	(const VCplxTrans t)	Transforms the polygon with the given complex transformation
[const]	DPath	**transformed**	(const DTrans t)	Transform the path.
[const]	DPath	**transformed**	(const DCplxTrans t)	Transform the path.
[const]	double	**width**		Get the width
	void	**width=**	(double w)	Set the width

Public static methods and constants

new DPath ptr	**from_s**	(string s)	Creates an object from a string

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**		Use of this method is deprecated. Use _create instead
	void	**destroy**		Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**		Use of this method is deprecated. Use _destroyed? instead
[static]	new DPath ptr	**from_ipath**	(const Path path)	Use of this method is deprecated. Use new instead
[const]	bool	**is_const_object?**		Use of this method is deprecated. Use _is_const_object? instead
[static]	new DPath ptr	**new_pw**	(DPoint[] pts, double width)	Use of this method is deprecated. Use new instead
[static]	new DPath ptr	**new_pwx**	(DPoint[] pts, double width, double bgn_ext, double end_ext)	Use of this method is deprecated. Use new instead
[static]	new DPath ptr	**new_pwxr**	(DPoint[] pts, double width, double bgn_ext, double end_ext, bool round)	Use of this method is deprecated. Use new instead
[const]	unsigned long	**points**		Use of this method is deprecated. Use num_points instead

[const]	DPath	**transformed_cplx**	(const DCplxTrans t)	Use of this method is deprecated. Use transformed instead

Detailed description

!=

Signature: *[const]* bool **!=** (const DPath p)

Description: Inequality test

p: The object to compare against

*****

Signature: *[const]* DPath ***** (double f)

Description: Scaling by some factor

Returns the scaled object. All coordinates are multiplied with the given factor and if necessary rounded.

Python specific notes:
This method also implements '__rmul__'.

<

Signature: *[const]* bool **<** (const DPath p)

Description: Less operator

p: The object to compare against

This operator is provided to establish some, not necessarily a certain sorting order

==

Signature: *[const]* bool **==** (const DPath p)

Description: Equality test

p: The object to compare against

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

area

Signature: *[const]* double **area**

Description: Returns the approximate area of the path

This method returns the approximate value of the area. It is computed from the length times the width. end extensions are taken into account correctly, but not effects of the corner interpolation. This method was added in version 0.22.

assign

Signature: void **assign** (const DPath other)

Description: Assigns another object to self

bbox

Signature: *[const]* DBox **bbox**

Description: Returns the bounding box of the path

bgn_ext

Signature: *[const]* double **bgn_ext**

Description: Get the begin extension

Python specific notes:
The object exposes a readable attribute 'bgn_ext'. This is the getter.

bgn_ext=

Signature: void **bgn_ext=** (double ext)

Description: Set the begin extension

Python specific notes:
The object exposes a writable attribute 'bgn_ext'. This is the setter.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

	Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
destroy	**Signature**: void **destroy** **Description**: Explicitly destroys the object Use of this method is deprecated. Use _destroy instead Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
destroyed?	**Signature**: *[const]* bool **destroyed?** **Description**: Returns a value indicating whether the object was already destroyed Use of this method is deprecated. Use _destroyed? instead This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
dup	**Signature**: *[const]* new DPath ptr **dup** **Description**: Creates a copy of self **Python specific notes:** This method also implements '__copy__' and '__deepcopy__'.
each_point	**Signature**: *[const,iter]* DPoint **each_point** **Description**: Get the points that make up the path's spine
end_ext	**Signature**: *[const]* double **end_ext** **Description**: Get the end extension **Python specific notes:** The object exposes a readable attribute 'end_ext'. This is the getter.
end_ext=	**Signature**: void **end_ext=** (double ext) **Description**: Set the end extension **Python specific notes:** The object exposes a writable attribute 'end_ext'. This is the setter.
from_ipath	**Signature**: *[static]* new DPath ptr **from_ipath** (const Path path) **Description**: Creates a floating-point coordinate path from an integer coordinate path Use of this method is deprecated. Use new instead This constructor has been introduced in version 0.25 and replaces the previous static method 'from_ipath'. **Python specific notes:** This method is the default initializer of the object.
from_s	**Signature**: *[static]* new DPath ptr **from_s** (string s) **Description**: Creates an object from a string Creates the object from a string representation (as returned by to_s)

This method has been added in version 0.23.

hash

Signature: *[const]* unsigned long **hash**

Description: Computes a hash value

Returns a hash value for the given polygon. This method enables polygons as hash keys.

This method has been introduced in version 0.25.

Python specific notes:
This method is also available as 'hash(object)'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_round?

Signature: *[const]* bool **is_round?**

Description: Returns true, if the path has round ends

Python specific notes:
The object exposes a readable attribute 'round'. This is the getter.

length

Signature: *[const]* double **length**

Description: Returns the length of the path

the length of the path is determined by summing the lengths of the segments and adding begin and end extensions. For round-ended paths the length of the paths between the tips of the ends.

This method was added in version 0.23.

move

(1) Signature: DPath **move** (const DVector p)

Description: Moves the path.

p:	The distance to move the path.
Returns:	The moved path.

Moves the path by the given offset and returns the moved path. The path is overwritten.

(2) Signature: DPath **move** (double dx, double dy)

Description: Moves the path.

dx:	The x distance to move the path.
dy:	The y distance to move the path.
Returns:	The moved path.

Moves the path by the given offset and returns the moved path. The path is overwritten.

This version has been added in version 0.23.

moved

(1) Signature: *[const]* DPath **moved** (const DVector p)

Description: Returns the moved path (does not change self)

p:	The distance to move the path.
Returns:	The moved path.

Moves the path by the given offset and returns the moved path. The path is not modified.

(2) Signature: *[const]* DPath **moved** (double dx, double dy)

Description: Returns the moved path (does not change self)

dx:	The x distance to move the path.
dy:	The y distance to move the path.
Returns:	The moved path.

Moves the path by the given offset and returns the moved path. The path is not modified.

This version has been added in version 0.23.

new

(1) Signature: *[static]* new DPath ptr **new** (const Path path)

Description: Creates a floating-point coordinate path from an integer coordinate path

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_ipath'.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new DPath ptr **new**

Description: Default constructor: creates an empty (invalid) path with width 0

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new DPath ptr **new** (DPoint[] pts, double width)

Description: Constructor given the points of the path's spine and the width

pts:	The points forming the spine of the path
width:	The width of the path

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new DPath ptr **new** (DPoint[] pts, double width, double bgn_ext, double end_ext)

Description: Constructor given the points of the path's spine, the width and the extensions

pts:	The points forming the spine of the path
width:	The width of the path
bgn_ext:	The begin extension of the path
end_ext:	The end extension of the path

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new DPath ptr **new** (DPoint[] pts, double width, double bgn_ext, double end_ext, bool round)

Description: Constructor given the points of the path's spine, the width, the extensions and the round end flag

pts:	The points forming the spine of the path
width:	The width of the path

bgn_ext: The begin extension of the path

end_ext: The end extension of the path

round: If this flag is true, the path will get rounded ends

Python specific notes:
This method is the default initializer of the object.

new_pw

Signature: *[static]* new DPath ptr **new_pw** (DPoint[] pts, double width)

Description: Constructor given the points of the path's spine and the width

pts: The points forming the spine of the path

width: The width of the path

Use of this method is deprecated. Use new instead

Python specific notes:
This method is the default initializer of the object.

new_pwx

Signature: *[static]* new DPath ptr **new_pwx** (DPoint[] pts, double width, double bgn_ext, double end_ext)

Description: Constructor given the points of the path's spine, the width and the extensions

pts: The points forming the spine of the path

width: The width of the path

bgn_ext: The begin extension of the path

end_ext: The end extension of the path

Use of this method is deprecated. Use new instead

Python specific notes:
This method is the default initializer of the object.

new_pwxr

Signature: *[static]* new DPath ptr **new_pwxr** (DPoint[] pts, double width, double bgn_ext, double end_ext, bool round)

Description: Constructor given the points of the path's spine, the width, the extensions and the round end flag

pts: The points forming the spine of the path

width: The width of the path

bgn_ext: The begin extension of the path

end_ext: The end extension of the path

round: If this flag is true, the path will get rounded ends

Use of this method is deprecated. Use new instead

Python specific notes:
This method is the default initializer of the object.

num_points

Signature: *[const]* unsigned long **num_points**

Description: Get the number of points

Python specific notes:
The object exposes a readable attribute 'points'. This is the getter.

perimeter

Signature: *[const]* double **perimeter**

Description: Returns the approximate perimeter of the path

This method returns the approximate value of the perimeter. It is computed from the length and the width. end extensions are taken into account correctly, but not effects of the corner interpolation. This method was added in version 0.24.4.

points

Signature: *[const]* unsigned long **points**

Description: Get the number of points

Use of this method is deprecated. Use num_points instead

Python specific notes:
The object exposes a readable attribute 'points'. This is the getter.

points=

Signature: void **points=** (DPoint[] p)

Description: Set the points of the path

p: An array of points to assign to the path's spine

Python specific notes:
The object exposes a writable attribute 'points'. This is the setter.

polygon

Signature: *[const]* DPolygon **polygon**

Description: Convert the path to a polygon

The returned polygon is not guaranteed to be non-self overlapping. This may happen if the path overlaps itself or contains very short segments.

round=

Signature: void **round=** (bool round_ends_flag)

Description: Set the 'round ends' flag

A path with round ends show half circles at the ends, instead of square or rectangular ends. Paths with this flag set should use a begin and end extension of half the width (see bgn_ext and end_ext). The interpretation of such paths in other tools may differ otherwise.

Python specific notes:
The object exposes a writable attribute 'round'. This is the setter.

round_corners

Signature: *[const]* DPath **round_corners** (double radius, int npoints, double accuracy)

Description: Creates a new path whose corners are interpolated with circular bends

radius: The radius of the bends

npoints: The number of points (per full circle) used for interpolating the bends

accuracy: The numerical accuracy of the computation

The accuracy parameter controls the numerical resolution of the approximation process and should be in the order of half the database unit. This accuracy is used for suppressing redundant points and simplification of the resulting path.

This method has been introduced in version 0.25.

simple_polygon

Signature: *[const]* DSimplePolygon **simple_polygon**

Description: Convert the path to a simple polygon

The returned polygon is not guaranteed to be non-selfoverlapping. This may happen if the path overlaps itself or contains very short segments.

to_itype

Signature: *[const]* Path **to_itype** (double dbu = 1)

Description: Converts the path to an integer coordinate path

The database unit can be specified to translate the floating-point coordinate path in micron units to an integer-coordinate path in database units. The path's' coordinates will be divided by the database unit.

This method has been introduced in version 0.25.

to_s

Signature: *[const]* string **to_s**

Description: Convert to a string

Python specific notes:
This method is also available as 'str(object)'.

transformed

(1) Signature: *[const]* Path **transformed** (const VCplxTrans t)

Description: Transforms the polygon with the given complex transformation

t:	The magnifying transformation to apply
Returns:	The transformed path (in this case an integer coordinate path)

This method has been introduced in version 0.25.

(2) Signature: *[const]* DPath **transformed** (const DTrans t)

Description: Transform the path.

t:	The transformation to apply.
Returns:	The transformed path.

Transforms the path with the given transformation. Does not modify the path but returns the transformed path.

(3) Signature: *[const]* DPath **transformed** (const DCplxTrans t)

Description: Transform the path.

t:	The transformation to apply.
Returns:	The transformed path.

Transforms the path with the given complex transformation. Does not modify the path but returns the transformed path.

transformed_cplx

Signature: *[const]* DPath **transformed_cplx** (const DCplxTrans t)

Description: Transform the path.

t:	The transformation to apply.
Returns:	The transformed path.

Use of this method is deprecated. Use transformed instead

Transforms the path with the given complex transformation. Does not modify the path but returns the transformed path.

width

Signature: *[const]* double **width**

Description: Get the width

Python specific notes:
The object exposes a readable attribute 'width'. This is the getter.

width=

Signature: void **width=** (double w)

Description: Set the width

Python specific notes:
The object exposes a writable attribute 'width'. This is the setter.

4.72. API reference - Class DPoint

Notation used in Ruby API documentation

Module: db

Description: A point class with double (floating-point) coordinates

Points represent a coordinate in the two-dimensional coordinate space of layout. They are not geometrical objects by itself. But they are frequently used in the database API for various purposes. Other than the integer variant (Point), points with floating-point coordinates can represent fractions of a database unit.

See The Database API for more details about the database objects.

Public constructors

new DPoint ptr	**new**	(const Point point)	Creates a floating-point coordinate point from an integer coordinate point
new DPoint ptr	**new**		Default constructor: creates a point at 0,0
new DPoint ptr	**new**	(const DVector v)	Default constructor: creates a point at from an vector
new DPoint ptr	**new**	(double x, double y)	Constructor for a point from two coordinate values

Public methods

[const]	bool	**!=**	(const DPoint p)	Inequality test operator
[const]	DPoint	*****	(double f)	Scaling by some factor
	DPoint	***=**	(double f)	Scaling by some factor
[const]	DPoint	**+**	(const DVector v)	Adds a vector to a point
[const]	DVector	**-**	(const DPoint p)	Subtract one point from another
[const]	DPoint	**-**	(const DVector v)	Subtract one vector from a point
[const]	DPoint	**-@**		Compute the negative of a point
[const]	DPoint	***/**	(double d)	Division by some divisor
	DPoint	***/=**	(double d)	Division by some divisor
[const]	bool	**<**	(const DPoint p)	"less" comparison operator
[const]	bool	**==**	(const DPoint p)	Equality test operator
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference

	void	_manage		Marks the object as managed by the script side.
	void	_unmanage		Marks the object as no longer owned by the script side.
[const]	double	abs		The absolute value of the point (Euclidian distance to 0,0)
	void	assign	(const DPoint other)	Assigns another object to self
[const]	double	distance	(const DPoint d)	The Euclidian distance to another point
[const]	new DPoint ptr	dup		Creates a copy of self
[const]	unsigned long	hash		Computes a hash value
[const]	double	sq_abs		The square of the absolute value of the point (Euclidian distance to 0,0)
[const]	double	sq_distance	(const DPoint d)	The square Euclidian distance to another point
[const]	Point	to_itype	(double dbu = 1)	Converts the point to an integer coordinate point
[const]	string	to_s	(double dbu = 0)	String conversion.
[const]	DVector	to_v		Turns the point into a vector
[const]	double	x		Accessor to the x coordinate
	void	x=	(double coord)	Write accessor to the x coordinate
[const]	double	y		Accessor to the y coordinate
	void	y=	(double coord)	Write accessor to the y coordinate

Public static methods and constants

new DPoint ptr	from_s	(string s)	Creates an object from a string

Deprecated methods (protected, public, static, non-static and constructors)

	void	create	Use of this method is deprecated. Use _create instead
	void	destroy	Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?	Use of this method is deprecated. Use _destroyed? instead

[static]	new DPoint ptr	**from_ipoint**	(const Point point)	Use of this method is deprecated. Use new instead
[const]	bool	**is_const_object?**		Use of this method is deprecated. Use _is_const_object? instead

Detailed description

!=

Signature: *[const]* bool **!=** (const DPoint p)
Description: Inequality test operator

*****

Signature: *[const]* DPoint ***** (double f)
Description: Scaling by some factor

Returns the scaled object. All coordinates are multiplied with the given factor and if necessary rounded.

Python specific notes:
This method also implements '__rmul__'.

***=**

Signature: DPoint ***=** (double f)
Description: Scaling by some factor

Scales object in place. All coordinates are multiplied with the given factor and if necessary rounded.

+

Signature: *[const]* DPoint **+** (const DVector v)
Description: Adds a vector to a point

Adds vector v to self by adding the coordinates.
Starting with version 0.25, this method expects a vector argument.

-

(1) Signature: *[const]* DVector **-** (const DPoint p)
Description: Subtract one point from another

Subtract point p from self by subtracting the coordinates. This renders a vector.
Starting with version 0.25, this method renders a vector.

(2) Signature: *[const]* DPoint **-** (const DVector v)
Description: Subtract one vector from a point

Subtract vector v from from self by subtracting the coordinates. This renders a point.
This method has been added in version 0.27.

-@

Signature: *[const]* DPoint **-@**
Description: Compute the negative of a point

Returns a new point with -x, -y.
This method has been added in version 0.23.

/

Signature: *[const]* DPoint **/** (double d)

Description: Division by some divisor

Returns the scaled object. All coordinates are divided with the given divisor and if necessary rounded.

/=

Signature: DPoint **/=** (double d)

Description: Division by some divisor

Divides the object in place. All coordinates are divided with the given divisor and if necessary rounded.

<

Signature: *[const]* bool **<** (const DPoint p)

Description: "less" comparison operator

This operator is provided to establish a sorting order

==

Signature: *[const]* bool **==** (const DPoint p)

Description: Equality test operator

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

abs

Signature: *[const]* double **abs**

Description: The absolute value of the point (Euclidian distance to 0,0)

The returned value is 'sqrt(x*x+y*y)'.

This method has been introduced in version 0.23.

assign

Signature: void **assign** (const DPoint other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

distance

Signature: *[const]* double **distance** (const DPoint d)

Description: The Euclidian distance to another point

d: The other point to compute the distance to.

dup

Signature: *[const]* new DPoint ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

from_ipoint

Signature: *[static]* new DPoint ptr **from_ipoint** (const Point point)

Description: Creates a floating-point coordinate point from an integer coordinate point

Use of this method is deprecated. Use new instead

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_ipoint'.

Python specific notes:
This method is the default initializer of the object.

from_s

Signature: *[static]* new DPoint ptr **from_s** (string s)

Description: Creates an object from a string

Creates the object from a string representation (as returned by to_s)

This method has been added in version 0.23.

hash

Signature: *[const]* unsigned long **hash**

Description: Computes a hash value

Returns a hash value for the given point. This method enables points as hash keys.

This method has been introduced in version 0.25.

Python specific notes:
This method is also available as 'hash(object)'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

(1) Signature: *[static]* new DPoint ptr **new** (const Point point)

Description: Creates a floating-point coordinate point from an integer coordinate point

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_ipoint'.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new DPoint ptr **new**

Description: Default constructor: creates a point at 0,0

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new DPoint ptr **new** (const DVector v)

Description: Default constructor: creates a point at from an vector

This constructor is equivalent to computing point(0,0)+v. This method has been introduced in version 0.25.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new DPoint ptr **new** (double x, double y)

Description: Constructor for a point from two coordinate values

Python specific notes:
This method is the default initializer of the object.

sq_abs

Signature: *[const]* double **sq_abs**

Description: The square of the absolute value of the point (Euclidian distance to 0,0)

The returned value is 'x*x+y*y'.

This method has been introduced in version 0.23.

sq_distance

Signature: *[const]* double **sq_distance** (const DPoint d)

Description: The square Euclidian distance to another point

d: The other point to compute the distance to.

to_itype

Signature: *[const]* Point **to_itype** (double dbu = 1)

Description: Converts the point to an integer coordinate point

The database unit can be specified to translate the floating-point coordinate point in micron units to an integer-coordinate point in database units. The point's' coordinates will be divided by the database unit.

This method has been introduced in version 0.25.

to_s

Signature: *[const]* string **to_s** (double dbu = 0)

Description: String conversion.

If a DBU is given, the output units will be micrometers.

The DBU argument has been added in version 0.27.6.

Python specific notes:
This method is also available as 'str(object)'.

to_v

Signature: *[const]* DVector **to_v**

Description: Turns the point into a vector

This method returns a vector representing the distance from (0,0) to the point.This method has been introduced in version 0.25.

x

Signature: *[const]* double **x**

Description: Accessor to the x coordinate

Python specific notes:
The object exposes a readable attribute 'x'. This is the getter.

x=

Signature: void **x=** (double coord)

Description: Write accessor to the x coordinate

Python specific notes:
The object exposes a writable attribute 'x'. This is the setter.

y

Signature: *[const]* double **y**

Description: Accessor to the y coordinate

Python specific notes:

The object exposes a readable attribute 'y'. This is the getter.

y=

Signature: void **y=** (double coord)

Description: Write accessor to the y coordinate

Python specific notes:
The object exposes a writable attribute 'y'. This is the setter.

4.73. API reference - Class Point

Notation used in Ruby API documentation

Module: db

Description: An integer point class

Points represent a coordinate in the two-dimensional coordinate space of layout. They are not geometrical objects by itself. But they are frequently used in the database API for various purposes.

See The Database API for more details about the database objects.

Public constructors

new Point ptr	**new**	(const DPoint dpoint)	Creates an integer coordinate point from a floating-point coordinate point
new Point ptr	**new**		Default constructor: creates a point at 0,0
new Point ptr	**new**	(const Vector v)	Default constructor: creates a point at from an vector
new Point ptr	**new**	(int x, int y)	Constructor for a point from two coordinate values

Public methods

[const]	bool	**!=**	(const Point p)	Inequality test operator
[const]	Point	*****	(double f)	Scaling by some factor
	Point	***=**	(double f)	Scaling by some factor
[const]	Point	**+**	(const Vector v)	Adds a vector to a point
[const]	Vector	**-**	(const Point p)	Subtract one point from another
[const]	Point	**-**	(const Vector v)	Subtract one vector from a point
[const]	Point	**-@**		Compute the negative of a point
[const]	Point	**/**	(double d)	Division by some divisor
	Point	**/=**	(double d)	Division by some divisor
[const]	bool	**<**	(const Point p)	"less" comparison operator
[const]	bool	**==**	(const Point p)	Equality test operator
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference

	void	_manage		Marks the object as managed by the script side.
	void	_unmanage		Marks the object as no longer owned by the script side.
[const]	double	abs		The absolute value of the point (Euclidian distance to 0,0)
	void	assign	(const Point other)	Assigns another object to self
[const]	double	distance	(const Point d)	The Euclidian distance to another point
[const]	new Point ptr	dup		Creates a copy of self
[const]	unsigned long	hash		Computes a hash value
[const]	double	sq_abs		The square of the absolute value of the point (Euclidian distance to 0,0)
[const]	double	sq_distance	(const Point d)	The square Euclidian distance to another point
[const]	DPoint	to_dtype	(double dbu = 1)	Converts the point to a floating-point coordinate point
[const]	string	to_s	(double dbu = 0)	String conversion.
[const]	Vector	to_v		Turns the point into a vector
[const]	int	x		Accessor to the x coordinate
	void	x=	(int coord)	Write accessor to the x coordinate
[const]	int	y		Accessor to the y coordinate
	void	y=	(int coord)	Write accessor to the y coordinate

Public static methods and constants

new Point ptr	from_s	(string s)	Creates an object from a string

Deprecated methods (protected, public, static, non-static and constructors)

	void	create		Use of this method is deprecated. Use _create instead
	void	destroy		Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?		Use of this method is deprecated. Use _destroyed? instead
[static]	new Point ptr	from_dpoint	(const DPoint dpoint)	Use of this method is deprecated. Use new instead

[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

!=

Signature: *[const]* bool **!=** (const Point p)
Description: Inequality test operator

*****

Signature: *[const]* Point ***** (double f)
Description: Scaling by some factor

Returns the scaled object. All coordinates are multiplied with the given factor and if necessary rounded.

Python specific notes:
This method also implements '__rmul__'.

***=**

Signature: Point ***=** (double f)
Description: Scaling by some factor

Scales object in place. All coordinates are multiplied with the given factor and if necessary rounded.

+

Signature: *[const]* Point **+** (const Vector v)
Description: Adds a vector to a point

Adds vector v to self by adding the coordinates.
Starting with version 0.25, this method expects a vector argument.

-

(1) Signature: *[const]* Vector **-** (const Point p)
Description: Subtract one point from another

Subtract point p from self by subtracting the coordinates. This renders a vector.
Starting with version 0.25, this method renders a vector.

(2) Signature: *[const]* Point **-** (const Vector v)
Description: Subtract one vector from a point

Subtract vector v from from self by subtracting the coordinates. This renders a point.
This method has been added in version 0.27.

-@

Signature: *[const]* Point **-@**
Description: Compute the negative of a point

Returns a new point with -x, -y.
This method has been added in version 0.23.

/

Signature: *[const]* Point **/** (double d)
Description: Division by some divisor

Returns the scaled object. All coordinates are divided with the given divisor and if necessary rounded.

/=

Signature: Point **/=** (double d)

Description: Division by some divisor

Divides the object in place. All coordinates are divided with the given divisor and if necessary rounded.

<

Signature: *[const]* bool **<** (const Point p)

Description: "less" comparison operator

This operator is provided to establish a sorting order

==

Signature: *[const]* bool **==** (const Point p)

Description: Equality test operator

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn

the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

abs

Signature: *[const]* double **abs**

Description: The absolute value of the point (Euclidian distance to 0,0)

The returned value is 'sqrt(x*x+y*y)'.

This method has been introduced in version 0.23.

assign

Signature: void **assign** (const Point other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

distance

Signature: *[const]* double **distance** (const Point d)

Description: The Euclidian distance to another point

d: The other point to compute the distance to.

dup

Signature: *[const]* new Point ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

from_dpoint

Signature: *[static]* new Point ptr **from_dpoint** (const DPoint dpoint)

Description: Creates an integer coordinate point from a floating-point coordinate point

Use of this method is deprecated. Use new instead

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_dpoint'.

Python specific notes:
This method is the default initializer of the object.

from_s

Signature: *[static]* new Point ptr **from_s** (string s)

Description: Creates an object from a string

Creates the object from a string representation (as returned by to_s)

This method has been added in version 0.23.

hash

Signature: *[const]* unsigned long **hash**

Description: Computes a hash value

Returns a hash value for the given point. This method enables points as hash keys.

This method has been introduced in version 0.25.

Python specific notes:
This method is also available as 'hash(object)'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

(1) Signature: *[static]* new Point ptr **new** (const DPoint dpoint)

Description: Creates an integer coordinate point from a floating-point coordinate point

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_dpoint'.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new Point ptr **new**

Description: Default constructor: creates a point at 0,0

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new Point ptr **new** (const Vector v)

Description: Default constructor: creates a point at from an vector

This constructor is equivalent to computing point(0,0)+v. This method has been introduced in version 0.25.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new Point ptr **new** (int x, int y)

Description: Constructor for a point from two coordinate values

Python specific notes:
This method is the default initializer of the object.

sq_abs

Signature: *[const]* double **sq_abs**

Description: The square of the absolute value of the point (Euclidian distance to 0,0)

The returned value is 'x*x+y*y'.

This method has been introduced in version 0.23.

sq_distance

Signature: *[const]* double **sq_distance** (const Point d)

Description: The square Euclidian distance to another point

d: The other point to compute the distance to.

to_dtype

Signature: *[const]* DPoint **to_dtype** (double dbu = 1)

Description: Converts the point to a floating-point coordinate point

The database unit can be specified to translate the integer-coordinate point into a floating-point coordinate point in micron units. The database unit is basically a scaling factor.

This method has been introduced in version 0.25.

to_s

Signature: *[const]* string **to_s** (double dbu = 0)

Description: String conversion.

If a DBU is given, the output units will be micrometers.

The DBU argument has been added in version 0.27.6.

Python specific notes:
This method is also available as 'str(object)'.

to_v

Signature: *[const]* Vector **to_v**

Description: Turns the point into a vector

This method returns a vector representing the distance from (0,0) to the point.This method has been introduced in version 0.25.

x

Signature: *[const]* int **x**

Description: Accessor to the x coordinate

Python specific notes:
The object exposes a readable attribute 'x'. This is the getter.

x=

Signature: void **x=** (int coord)

Description: Write accessor to the x coordinate

Python specific notes:
The object exposes a writable attribute 'x'. This is the setter.

y

Signature: *[const]* int **y**

Description: Accessor to the y coordinate

Python specific notes:
The object exposes a readable attribute 'y'. This is the getter.

y=

Signature: void **y=** (int coord)

Description: Write accessor to the y coordinate

Python specific notes:
The object exposes a writable attribute 'y'. This is the setter.

4.74. API reference - Class SimplePolygon

Notation used in Ruby API documentation

Module: db

Description: A simple polygon class

A simple polygon consists of an outer hull only. To support polygons with holes, use Polygon. The hull contour consists of several points. The point list is normalized such that the leftmost, lowest point is the first one. The orientation is normalized such that the orientation of the hull contour is clockwise.

It is in no way checked that the contours are not overlapping This must be ensured by the user of the object when filling the contours.

The SimplePolygon class stores coordinates in integer format. A class that stores floating-point coordinates is DSimplePolygon.

See The Database API for more details about the database objects.

Public constructors

new SimplePolygon ptr	**new**	(const DSimplePolygon dpolygon)	Creates an integer coordinate polygon from a floating-point coordinate polygon
new SimplePolygon ptr	**new**		Default constructor: creates an empty (invalid) polygon
new SimplePolygon ptr	**new**	(Point[] pts, bool raw = false)	Constructor given the points of the simple polygon
new SimplePolygon ptr	**new**	(const Box box)	Constructor converting a box to a polygon

Public methods

[const]	bool	**!=**	(const SimplePolygon p)	Returns a value indicating whether self is not equal to p
[const]	SimplePolygon	*****	(double f)	Scales the polygon by some factor
[const]	bool	**<**	(const SimplePolygon p)	Returns a value indicating whether self is less than p
[const]	bool	**==**	(const SimplePolygon p)	Returns a value indicating whether self is equal to p
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.

[const]	long	**area**		Gets the area of the polygon
[const]	long	**area2**		Gets the double area of the polygon
	void	**assign**	(const SimplePolygon other)	Assigns another object to self
[const]	Box	**bbox**		Returns the bounding box of the simple polygon
[const]	SimplePolygon[]	**break**	(unsigned long max_vertex_count, double max_area_ratio)	Splits the polygon into parts with a maximum vertex count and area ratio
	void	**compress**	(bool remove_reflected)	Compressed the simple polygon.
[const]	new SimplePolygon ptr	**dup**		Creates a copy of self
[const,iter]	Edge	**each_edge**		Iterates over the edges that make up the simple polygon
[const,iter]	Point	**each_point**		Iterates over the points that make up the simple polygon
[const]	variant[]	**extract_rad**		Extracts the corner radii from a rounded polygon
[const]	unsigned long	**hash**		Computes a hash value
[const]	bool	**inside?**	(Point p)	Gets a value indicating whether the given point is inside the polygon
[const]	bool	**is_box?**		Returns a value indicating whether the polygon is a simple box.
[const]	bool	**is_empty?**		Returns a value indicating whether the polygon is empty
[const]	bool	**is_halfmanhattan?**		Returns a value indicating whether the polygon is half-manhattan
[const]	bool	**is_rectilinear?**		Returns a value indicating whether the polygon is rectilinear
[const]	Polygon	**minkowski_sum**	(const Edge e, bool resolve_holes)	Computes the Minkowski sum of a polygon and an edge
[const]	Polygon	**minkowski_sum**	(const SimplePolygon p, bool resolve_holes)	Computes the Minkowski sum of a polygon and a polygon
[const]	Polygon	**minkowski_sum**	(const Box b,	Computes the Minkowski sum of a polygon and a box

			bool resolve_holes)	
[const]	Polygon	**minkowski_sum**	(Point[] c, bool resolve_holes)	Computes the Minkowski sum of a polygon and a contour of points (a trace)
	SimplePolygon	**move**	(const Vector p)	Moves the simple polygon.
	SimplePolygon	**move**	(int x, int y)	Moves the polygon.
[const]	SimplePolygon	**moved**	(const Vector p)	Returns the moved simple polygon
[const]	SimplePolygon	**moved**	(int x, int y)	Returns the moved polygon (does not modify self)
[const]	unsigned long	**num_points**		Gets the number of points
[const]	unsigned long	**perimeter**		Gets the perimeter of the polygon
[const]	Point	**point**	(unsigned long p)	Gets a specific point of the contour@param p The index of the point to get
	void	**points=**	(Point[] pts)	Sets the points of the simple polygon
[const]	SimplePolygon	**round_corners**	(double rinner, double router, unsigned int n)	Rounds the corners of the polygon
	void	**set_points**	(Point[] pts, bool raw = false)	Sets the points of the simple polygon
[const]	SimplePolygon[]	**split**		Splits the polygon into two or more parts
[const]	DSimplePolygon	**to_dtype**	(double dbu = 1)	Converts the polygon to a floating-point coordinate polygon
[const]	string	**to_s**		Returns a string representing the polygon
[const]	bool	**touches?**	(const Box box)	Returns true, if the polygon touches the given box.
[const]	bool	**touches?**	(const Edge edge)	Returns true, if the polygon touches the given edge.
[const]	bool	**touches?**	(const Polygon polygon)	Returns true, if the polygon touches the other polygon.
[const]	bool	**touches?**	(const SimplePolygon simple_polygon)	Returns true, if the polygon touches the other polygon.
	SimplePolygon ptr	**transform**	(const ICplxTrans t)	Transforms the simple polygon with a complex transformation (in-place)
	SimplePolygon ptr	**transform**	(const Trans t)	Transforms the simple polygon (in-place)

[const]	SimplePolygon	**transformed**	(const ICplxTrans t)	Transforms the simple polygon.
[const]	SimplePolygon	**transformed**	(const Trans t)	Transforms the simple polygon.
[const]	DSimplePolygon	**transformed**	(const CplxTrans t)	Transforms the simple polygon.

Public static methods and constants

	new SimplePolygon ptr	**ellipse**	(const Box box, int n)	Creates a simple polygon approximating an ellipse
	new SimplePolygon ptr	**from_s**	(string s)	Creates an object from a string

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**		Use of this method is deprecated. Use _create instead
	void	**destroy**		Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**		Use of this method is deprecated. Use _destroyed? instead
[static]	new SimplePolygon ptr	**from_dpoly**	(const DSimplePolygon dpolygon)	Use of this method is deprecated. Use new instead
[const]	bool	**is_const_object?**		Use of this method is deprecated. Use _is_const_object? instead
[const]	Polygon	**minkowsky_sum**	(const Edge e, bool resolve_holes)	Use of this method is deprecated. Use minkowski_sum instead
[const]	Polygon	**minkowsky_sum**	(const SimplePolygon p, bool resolve_holes)	Use of this method is deprecated. Use minkowski_sum instead
[const]	Polygon	**minkowsky_sum**	(const Box b, bool resolve_holes)	Use of this method is deprecated. Use minkowski_sum instead
[const]	Polygon	**minkowsky_sum**	(Point[] c, bool resolve_holes)	Use of this method is deprecated. Use minkowski_sum instead
[const]	DSimplePolygon	**transformed_cplx**	(const CplxTrans t)	Use of this method is deprecated. Use transformed instead

Detailed description

!=

Signature: *[const]* bool **!=** (const SimplePolygon p)

Description: Returns a value indicating whether self is not equal to p

p: The object to compare against

*****

Signature: *[const]* SimplePolygon ***** (double f)

Description: Scales the polygon by some factor

Returns the scaled object. All coordinates are multiplied with the given factor and if necessary rounded.

Python specific notes:
This method also implements '__rmul__'.

<

Signature: *[const]* bool **<** (const SimplePolygon p)

Description: Returns a value indicating whether self is less than p

p: The object to compare against

This operator is provided to establish some, not necessarily a certain sorting order

This method has been introduced in version 0.25.

==

Signature: *[const]* bool **==** (const SimplePolygon p)

Description: Returns a value indicating whether self is equal to p

p: The object to compare against

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

	Usually it's not required to call this method. It has been introduced in version 0.24.
_unmanage	**Signature**: void **_unmanage** **Description**: Marks the object as no longer owned by the script side. Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.
area	**Signature**: *[const]* long **area** **Description**: Gets the area of the polygon The area is correct only if the polygon is not self-overlapping and the polygon is oriented clockwise.
area2	**Signature**: *[const]* long **area2** **Description**: Gets the double area of the polygon This method is provided because the area for an integer-type polygon is a multiple of 1/2. Hence the double area can be expresses precisely as an integer for these types. This method has been introduced in version 0.26.1
assign	**Signature**: void **assign** (const SimplePolygon other) **Description**: Assigns another object to self
bbox	**Signature**: *[const]* Box **bbox** **Description**: Returns the bounding box of the simple polygon
break	**Signature**: *[const]* SimplePolygon[] **break** (unsigned long max_vertex_count, double max_area_ratio) **Description**: Splits the polygon into parts with a maximum vertex count and area ratio The area ratio is the ratio between the bounding box area and the polygon area. Higher values mean more 'skinny' polygons. This method will split the input polygon into pieces having a maximum of 'max_vertex_count' vertices and an area ratio less than 'max_area_ratio'. 'max_vertex_count' can be zero. In this case the limit is ignored. Also 'max_area_ratio' can be zero, in which case it is ignored as well. The method of splitting is unspecified. The algorithm will apply 'split' recursively until the parts satisfy the limits. This method has been introduced in version 0.29. **Python specific notes:** This attribute is available as 'break_' in Python.
compress	**Signature**: void **compress** (bool remove_reflected) **Description**: Compressed the simple polygon. **remove_reflected**: See description of the functionality.

This method removes redundant points from the polygon, such as points being on a line formed by two other points. If remove_reflected is true, points are also removed if the two adjacent edges form a spike.

This method was introduced in version 0.18.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new SimplePolygon ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

each_edge

Signature: *[const,iter]* Edge **each_edge**

Description: Iterates over the edges that make up the simple polygon

each_point

Signature: *[const,iter]* Point **each_point**

Description: Iterates over the points that make up the simple polygon

ellipse

Signature: *[static]* new SimplePolygon ptr **ellipse** (const Box box, int n)

Description: Creates a simple polygon approximating an ellipse

box: The bounding box of the ellipse

n: The number of points that will be used to approximate the ellipse

This method has been introduced in version 0.23.

extract_rad

Signature: *[const]* variant[] **extract_rad**

Description: Extracts the corner radii from a rounded polygon

Attempts to extract the radii of rounded corner polygon. This is essentially the inverse of the round_corners method. If this method succeeds, if will return an array of four elements:

- The polygon with the rounded corners replaced by edgy ones
- The radius of the inner corners
- The radius of the outer corners
- The number of points per full circle

This method is based on some assumptions and may fail. In this case, an empty array is returned.

If successful, the following code will more or less render the original polygon and parameters

```
p = ...   # some polygon
p.round_corners(ri, ro, n)
(p2, ri2, ro2, n2) = p.extract_rad
# -> p2 == p, ro2 == ro, ri2 == ri, n2 == n (within some limits)
```

This method was introduced in version 0.25.

from_dpoly

Signature: *[static]* new SimplePolygon ptr **from_dpoly** (const DSimplePolygon dpolygon)

Description: Creates an integer coordinate polygon from a floating-point coordinate polygon

Use of this method is deprecated. Use new instead

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_dpoly'.

Python specific notes:
This method is the default initializer of the object.

from_s

Signature: *[static]* new SimplePolygon ptr **from_s** (string s)

Description: Creates an object from a string

Creates the object from a string representation (as returned by to_s)

This method has been added in version 0.23.

hash

Signature: *[const]* unsigned long **hash**

Description: Computes a hash value

Returns a hash value for the given polygon. This method enables polygons as hash keys.

This method has been introduced in version 0.25.

Python specific notes:
This method is also available as 'hash(object)'.

inside?

Signature: *[const]* bool **inside?** (Point p)

Description: Gets a value indicating whether the given point is inside the polygon

If the given point is inside or on the edge the polygon, true is returned. This tests works well only if the polygon is not self-overlapping and oriented clockwise.

is_box?

Signature: *[const]* bool **is_box?**

Description: Returns a value indicating whether the polygon is a simple box.

Returns: True if the polygon is a box.

A polygon is a box if it is identical to its bounding box.

This method was introduced in version 0.23.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_empty?

Signature: *[const]* bool **is_empty?**

Description: Returns a value indicating whether the polygon is empty

is_halfmanhattan?

Signature: *[const]* bool **is_halfmanhattan?**

Description: Returns a value indicating whether the polygon is half-manhattan

Half-manhattan polygons have edges which are multiples of 45 degree. These polygons can be clipped at a rectangle without potential grid snapping.

This predicate was introduced in version 0.27.

is_rectilinear?

Signature: *[const]* bool **is_rectilinear?**

Description: Returns a value indicating whether the polygon is rectilinear

minkowski_sum

(1) Signature: *[const]* Polygon **minkowski_sum** (const Edge e, bool resolve_holes)

Description: Computes the Minkowski sum of a polygon and an edge

e:	The edge.
resolve_holes:	If true, the output polygon will not contain holes, but holes are resolved by joining the holes with the hull.
Returns:	The new polygon representing the Minkowski sum of self and e.

This method was introduced in version 0.22.

(2) Signature: *[const]* Polygon **minkowski_sum** (const SimplePolygon p, bool resolve_holes)

Description: Computes the Minkowski sum of a polygon and a polygon

p:	The other polygon.
resolve_holes:	If true, the output polygon will not contain holes, but holes are resolved by joining the holes with the hull.
Returns:	The new polygon representing the Minkowski sum of self and p.

This method was introduced in version 0.22.

(3) Signature: *[const]* Polygon **minkowski_sum** (const Box b, bool resolve_holes)

Description: Computes the Minkowski sum of a polygon and a box

b:	The box.
resolve_holes:	If true, the output polygon will not contain holes, but holes are resolved by joining the holes with the hull.
Returns:	The new polygon representing the Minkowski sum of self and b.

This method was introduced in version 0.22.

(4) Signature: *[const]* Polygon **minkowski_sum** (Point[] c, bool resolve_holes)

Description: Computes the Minkowski sum of a polygon and a contour of points (a trace)

c:	The contour (a series of points forming the trace).
resolve_holes:	If true, the output polygon will not contain holes, but holes are resolved by joining the holes with the hull.
Returns:	The new polygon representing the Minkowski sum of self and c.

This method was introduced in version 0.22.

minkowsky_sum

(1) Signature: *[const]* Polygon **minkowsky_sum** (const Edge e, bool resolve_holes)

Description: Computes the Minkowski sum of a polygon and an edge

e:	The edge.
resolve_holes:	If true, the output polygon will not contain holes, but holes are resolved by joining the holes with the hull.
Returns:	The new polygon representing the Minkowski sum of self and e.

Use of this method is deprecated. Use minkowski_sum instead

This method was introduced in version 0.22.

(2) Signature: *[const]* Polygon **minkowsky_sum** (const SimplePolygon p, bool resolve_holes)

Description: Computes the Minkowski sum of a polygon and a polygon

p:	The other polygon.
resolve_holes:	If true, the output polygon will not contain holes, but holes are resolved by joining the holes with the hull.
Returns:	The new polygon representing the Minkowski sum of self and p.

Use of this method is deprecated. Use minkowski_sum instead

This method was introduced in version 0.22.

(3) Signature: *[const]* Polygon **minkowsky_sum** (const Box b, bool resolve_holes)

Description: Computes the Minkowski sum of a polygon and a box

b:	The box.
resolve_holes:	If true, the output polygon will not contain holes, but holes are resolved by joining the holes with the hull.
Returns:	The new polygon representing the Minkowski sum of self and b.

Use of this method is deprecated. Use minkowski_sum instead

This method was introduced in version 0.22.

(4) Signature: *[const]* Polygon **minkowsky_sum** (Point[] c, bool resolve_holes)

Description: Computes the Minkowski sum of a polygon and a contour of points (a trace)

c:	The contour (a series of points forming the trace).
resolve_holes:	If true, the output polygon will not contain holes, but holes are resolved by joining the holes with the hull.
Returns:	The new polygon representing the Minkowski sum of self and c.

Use of this method is deprecated. Use minkowski_sum instead

This method was introduced in version 0.22.

move

(1) Signature: SimplePolygon **move** (const Vector p)

Description: Moves the simple polygon.

p: The distance to move the simple polygon.

Returns: The moved simple polygon.

Moves the simple polygon by the given offset and returns the moved simple polygon. The polygon is overwritten.

(2) Signature: SimplePolygon **move** (int x, int y)

Description: Moves the polygon.

x: The x distance to move the polygon.

y: The y distance to move the polygon.

Returns: The moved polygon (self).

Moves the polygon by the given offset and returns the moved polygon. The polygon is overwritten.

moved

(1) Signature: *[const]* SimplePolygon **moved** (const Vector p)

Description: Returns the moved simple polygon

p: The distance to move the simple polygon.

Returns: The moved simple polygon.

Moves the simple polygon by the given offset and returns the moved simple polygon. The polygon is not modified.

(2) Signature: *[const]* SimplePolygon **moved** (int x, int y)

Description: Returns the moved polygon (does not modify self)

x: The x distance to move the polygon.

y: The y distance to move the polygon.

Returns: The moved polygon.

Moves the polygon by the given offset and returns the moved polygon. The polygon is not modified.

This method has been introduced in version 0.23.

new

(1) Signature: *[static]* new SimplePolygon ptr **new** (const DSimplePolygon dpolygon)

Description: Creates an integer coordinate polygon from a floating-point coordinate polygon

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_dpoly'.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new SimplePolygon ptr **new**

Description: Default constructor: creates an empty (invalid) polygon

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new SimplePolygon ptr **new** (Point[] pts, bool raw = false)

Description: Constructor given the points of the simple polygon

pts: The points forming the simple polygon

raw: If true, the points are taken as they are (see below)

If the 'raw' argument is set to true, the points are taken as they are. Specifically no removal of redundant points or joining of coincident edges will take place. In effect, polygons consisting of a single point or two points can be constructed as well as polygons with duplicate points. Note that such polygons may cause problems in some applications.

Regardless of raw mode, the point list will be adjusted such that the first point is the lowest-leftmost one and the orientation is clockwise always.

The 'raw' argument has been added in version 0.24.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new SimplePolygon ptr **new** (const Box box)

Description: Constructor converting a box to a polygon

box: The box to convert to a polygon

Python specific notes:
This method is the default initializer of the object.

num_points

Signature: *[const]* unsigned long **num_points**

Description: Gets the number of points

perimeter

Signature: *[const]* unsigned long **perimeter**

Description: Gets the perimeter of the polygon

The perimeter is sum of the lengths of all edges making up the polygon.

point

Signature: *[const]* Point **point** (unsigned long p)

Description: Gets a specific point of the contour@param p The index of the point to get

If the index of the point is not a valid index, a default value is returned. This method was introduced in version 0.18.

points=

Signature: void **points=** (Point[] pts)

Description: Sets the points of the simple polygon

pts: An array of points to assign to the simple polygon

See the constructor description for details about raw mode.

Python specific notes:
The object exposes a writable attribute 'points'. This is the setter.

round_corners

Signature: *[const]* SimplePolygon **round_corners** (double rinner, double router, unsigned int n)

Description: Rounds the corners of the polygon

rinner: The circle radius of inner corners (in database units).

router: The circle radius of outer corners (in database units).

n: The number of points per full circle.

Returns: The new polygon.

Replaces the corners of the polygon with circle segments.

This method was introduced in version 0.22 for integer coordinates and in 0.25 for all coordinate types.

set_points

Signature: void **set_points** (Point[] pts, bool raw = false)

Description: Sets the points of the simple polygon

pts: An array of points to assign to the simple polygon

raw: If true, the points are taken as they are

See the constructor description for details about raw mode.

This method has been added in version 0.24.

split

Signature: *[const]* SimplePolygon[] **split**

Description: Splits the polygon into two or more parts

This method will break the polygon into parts. The exact breaking algorithm is unspecified, the result are smaller polygons of roughly equal number of points and 'less concave' nature. Usually the returned polygon set consists of two polygons, but there can be more. The merged region of the resulting polygons equals the original polygon with the exception of small snapping effects at new vertexes.

The intended use for this method is a iteratively split polygons until the satisfy some maximum number of points limit.

This method has been introduced in version 0.25.3.

to_dtype

Signature: *[const]* DSimplePolygon **to_dtype** (double dbu = 1)

Description: Converts the polygon to a floating-point coordinate polygon

The database unit can be specified to translate the integer-coordinate polygon into a floating-point coordinate polygon in micron units. The database unit is basically a scaling factor.

This method has been introduced in version 0.25.

to_s

Signature: *[const]* string **to_s**

Description: Returns a string representing the polygon

Python specific notes:
This method is also available as 'str(object)'.

touches?

(1) Signature: *[const]* bool **touches?** (const Box box)

Description: Returns true, if the polygon touches the given box.

The box and the polygon touch if they overlap or their contours share at least one point.

This method was introduced in version 0.25.1.

(2) Signature: *[const]* bool **touches?** (const Edge edge)

Description: Returns true, if the polygon touches the given edge.

The edge and the polygon touch if they overlap or the edge shares at least one point with the polygon's contour.

This method was introduced in version 0.25.1.

(3) Signature: *[const]* bool **touches?** (const Polygon polygon)

Description: Returns true, if the polygon touches the other polygon.

The polygons touch if they overlap or their contours share at least one point.

This method was introduced in version 0.25.1.

(4) Signature: *[const]* bool **touches?** (const SimplePolygon simple_polygon)

Description: Returns true, if the polygon touches the other polygon.

The polygons touch if they overlap or their contours share at least one point.

This method was introduced in version 0.25.1.

transform

(1) Signature: SimplePolygon ptr **transform** (const ICplxTrans t)

Description: Transforms the simple polygon with a complex transformation (in-place)

t: The transformation to apply.

Transforms the simple polygon with the given complex transformation. Modifies self and returns self. An out-of-place version which does not modify self is transformed.

This method has been introduced in version 0.24.

(2) Signature: SimplePolygon ptr **transform** (const Trans t)

Description: Transforms the simple polygon (in-place)

t: The transformation to apply.

Transforms the simple polygon with the given transformation. Modifies self and returns self. An out-of-place version which does not modify self is transformed.

This method has been introduced in version 0.24.

transformed

(1) Signature: *[const]* SimplePolygon **transformed** (const ICplxTrans t)

Description: Transforms the simple polygon.

t: The transformation to apply.

Returns: The transformed simple polygon (in this case an integer coordinate object).

Transforms the simple polygon with the given complex transformation. Does not modify the simple polygon but returns the transformed polygon.

This method has been introduced in version 0.18.

(2) Signature: *[const]* SimplePolygon **transformed** (const Trans t)

Description: Transforms the simple polygon.

t: The transformation to apply.

Returns: The transformed simple polygon.

Transforms the simple polygon with the given transformation. Does not modify the simple polygon but returns the transformed polygon.

(3) Signature: *[const]* DSimplePolygon **transformed** (const CplxTrans t)

Description: Transforms the simple polygon.

t: The transformation to apply.

Returns: The transformed simple polygon.

Transforms the simple polygon with the given complex transformation. Does not modify the simple polygon but returns the transformed polygon.

With version 0.25, the original 'transformed_cplx' method is deprecated and 'transformed' takes both simple and complex transformations.

transformed_cplx

Signature: *[const]* DSimplePolygon **transformed_cplx** (const CplxTrans t)

Description: Transforms the simple polygon.

t:	The transformation to apply.
Returns:	The transformed simple polygon.

Use of this method is deprecated. Use transformed instead

Transforms the simple polygon with the given complex transformation. Does not modify the simple polygon but returns the transformed polygon.

With version 0.25, the original 'transformed_cplx' method is deprecated and 'transformed' takes both simple and complex transformations.

4.75. API reference - Class DSimplePolygon

Notation used in Ruby API documentation

Module: db

Description: A simple polygon class

A simple polygon consists of an outer hull only. To support polygons with holes, use DPolygon. The contour consists of several points. The point list is normalized such that the leftmost, lowest point is the first one. The orientation is normalized such that the orientation of the hull contour is clockwise.

It is in no way checked that the contours are not over- lapping. This must be ensured by the user of the object when filling the contours.

The DSimplePolygon class stores coordinates in floating-point format which gives a higher precision for some operations. A class that stores integer coordinates is SimplePolygon.

See The Database API for more details about the database objects.

Public constructors

new DSimplePolygon ptr	**new**	(const SimplePolygon polygon)	Creates a floating-point coordinate polygon from an integer coordinate polygon
new DSimplePolygon ptr	**new**		Default constructor: creates an empty (invalid) polygon
new DSimplePolygon ptr	**new**	(DPoint[] pts, bool raw = false)	Constructor given the points of the simple polygon
new DSimplePolygon ptr	**new**	(const DBox box)	Constructor converting a box to a polygon

Public methods

[const]	bool	**!=**	(const DSimplePolygon p)	Returns a value indicating whether self is not equal to p
[const]	DSimplePolygon	*****	(double f)	Scales the polygon by some factor
[const]	bool	**<**	(const DSimplePolygon p)	Returns a value indicating whether self is less than p
[const]	bool	**==**	(const DSimplePolygon p)	Returns a value indicating whether self is equal to p
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.

	void	_unmanage		Marks the object as no longer owned by the script side.
[const]	double	area		Gets the area of the polygon
[const]	double	area2		Gets the double area of the polygon
	void	assign	(const DSimplePolygon other)	Assigns another object to self
[const]	DBox	bbox		Returns the bounding box of the simple polygon
[const]	DSimplePolygon[]	break	(unsigned long max_vertex_count, double max_area_ratio)	Splits the polygon into parts with a maximum vertex count and area ratio
	void	compress	(bool remove_reflected)	Compressed the simple polygon.
[const]	new DSimplePolygon ptr	dup		Creates a copy of self
[const,iter]	DEdge	each_edge		Iterates over the edges that make up the simple polygon
[const,iter]	DPoint	each_point		Iterates over the points that make up the simple polygon
[const]	variant[]	extract_rad		Extracts the corner radii from a rounded polygon
[const]	unsigned long	hash		Computes a hash value
[const]	bool	inside?	(DPoint p)	Gets a value indicating whether the given point is inside the polygon
[const]	bool	is_box?		Returns a value indicating whether the polygon is a simple box.
[const]	bool	is_empty?		Returns a value indicating whether the polygon is empty
[const]	bool	is_halfmanhattan?		Returns a value indicating whether the polygon is half-manhattan
[const]	bool	is_rectilinear?		Returns a value indicating whether the polygon is rectilinear
	DSimplePolygon	move	(const DVector p)	Moves the simple polygon.
	DSimplePolygon	move	(double x, double y)	Moves the polygon.
[const]	DSimplePolygon	moved	(const DVector p)	Returns the moved simple polygon

[const]	DSimplePolygon	**moved**	(double x, double y)	Returns the moved polygon (does not modify self)
[const]	unsigned long	**num_points**		Gets the number of points
[const]	double	**perimeter**		Gets the perimeter of the polygon
[const]	DPoint	**point**	(unsigned long p)	Gets a specific point of the contour@param p The index of the point to get
	void	**points=**	(DPoint[] pts)	Sets the points of the simple polygon
[const]	DSimplePolygon	**round_corners**	(double rinner, double router, unsigned int n)	Rounds the corners of the polygon
	void	**set_points**	(DPoint[] pts, bool raw = false)	Sets the points of the simple polygon
[const]	DSimplePolygon[]	**split**		Splits the polygon into two or more parts
[const]	SimplePolygon	**to_itype**	(double dbu = 1)	Converts the polygon to an integer coordinate polygon
[const]	string	**to_s**		Returns a string representing the polygon
[const]	bool	**touches?**	(const DBox box)	Returns true, if the polygon touches the given box.
[const]	bool	**touches?**	(const DEdge edge)	Returns true, if the polygon touches the given edge.
[const]	bool	**touches?**	(const DPolygon polygon)	Returns true, if the polygon touches the other polygon.
[const]	bool	**touches?**	(const DSimplePolygon simple_polygon)	Returns true, if the polygon touches the other polygon.
	DSimplePolygon ptr	**transform**	(const DCplxTrans t)	Transforms the simple polygon with a complex transformation (in-place)
	DSimplePolygon ptr	**transform**	(const DTrans t)	Transforms the simple polygon (in-place)
[const]	SimplePolygon	**transformed**	(const VCplxTrans t)	Transforms the polygon with the given complex transformation
[const]	DSimplePolygon	**transformed**	(const DTrans t)	Transforms the simple polygon.
[const]	DSimplePolygon	**transformed**	(const DCplxTrans t)	Transforms the simple polygon.

Public static methods and constants

new DSimplePolygon ptr	**ellipse**	(const DBox box, int n)	Creates a simple polygon approximating an ellipse

	new DSimplePolygon ptr	**from_s**	(string s)	Creates an object from a string

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**		Use of this method is deprecated. Use _create instead
	void	**destroy**		Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**		Use of this method is deprecated. Use _destroyed? instead
[static]	new DSimplePolygon ptr	**from_ipoly**	(const SimplePolygon polygon)	Use of this method is deprecated. Use new instead
[const]	bool	**is_const_object?**		Use of this method is deprecated. Use _is_const_object? instead
[const]	DSimplePolygon	**transformed_cplx**	(const DCplxTrans t)	Use of this method is deprecated. Use transformed instead

Detailed description

!=

Signature: *[const]* bool **!=** (const DSimplePolygon p)

Description: Returns a value indicating whether self is not equal to p

p: The object to compare against

*****

Signature: *[const]* DSimplePolygon ***** (double f)

Description: Scales the polygon by some factor

Returns the scaled object. All coordinates are multiplied with the given factor and if necessary rounded.

Python specific notes:
This method also implements '__rmul__'.

<

Signature: *[const]* bool **<** (const DSimplePolygon p)

Description: Returns a value indicating whether self is less than p

p: The object to compare against

This operator is provided to establish some, not necessarily a certain sorting order

This method has been introduced in version 0.25.

==

Signature: *[const]* bool **==** (const DSimplePolygon p)

Description: Returns a value indicating whether self is equal to p

p: The object to compare against

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

area

Signature: *[const]* double **area**

Description: Gets the area of the polygon

The area is correct only if the polygon is not self-overlapping and the polygon is oriented clockwise.

area2

Signature: *[const]* double **area2**

Description: Gets the double area of the polygon

This method is provided because the area for an integer-type polygon is a multiple of 1/2. Hence the double area can be expresses precisely as an integer for these types.

This method has been introduced in version 0.26.1

assign

Signature: void **assign** (const DSimplePolygon other)

Description: Assigns another object to self

bbox

Signature: *[const]* DBox **bbox**

Description: Returns the bounding box of the simple polygon

break

Signature: *[const]* DSimplePolygon[] **break** (unsigned long max_vertex_count, double max_area_ratio)

Description: Splits the polygon into parts with a maximum vertex count and area ratio

The area ratio is the ratio between the bounding box area and the polygon area. Higher values mean more 'skinny' polygons.

This method will split the input polygon into pieces having a maximum of 'max_vertex_count' vertices and an area ratio less than 'max_area_ratio'. 'max_vertex_count' can be zero. In this case the limit is ignored. Also 'max_area_ratio' can be zero, in which case it is ignored as well.

The method of splitting is unspecified. The algorithm will apply 'split' recursively until the parts satisfy the limits.

This method has been introduced in version 0.29.

Python specific notes:
This attribute is available as 'break_' in Python.

compress

Signature: void **compress** (bool remove_reflected)

Description: Compressed the simple polygon.

remove_reflected: See description of the functionality.

This method removes redundant points from the polygon, such as points being on a line formed by two other points. If remove_reflected is true, points are also removed if the two adjacent edges form a spike.

This method was introduced in version 0.18.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new DSimplePolygon ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

each_edge

Signature: *[const,iter]* DEdge **each_edge**

Description: Iterates over the edges that make up the simple polygon

each_point

Signature: *[const,iter]* DPoint **each_point**

Description: Iterates over the points that make up the simple polygon

ellipse

Signature: *[static]* new DSimplePolygon ptr **ellipse** (const DBox box, int n)

Description: Creates a simple polygon approximating an ellipse

box: The bounding box of the ellipse

n: The number of points that will be used to approximate the ellipse

This method has been introduced in version 0.23.

extract_rad

Signature: *[const]* variant[] **extract_rad**

Description: Extracts the corner radii from a rounded polygon

Attempts to extract the radii of rounded corner polygon. This is essentially the inverse of the round_corners method. If this method succeeds, if will return an array of four elements:

- The polygon with the rounded corners replaced by edgy ones
- The radius of the inner corners
- The radius of the outer corners
- The number of points per full circle

This method is based on some assumptions and may fail. In this case, an empty array is returned.

If successful, the following code will more or less render the original polygon and parameters

```
p = ...   # some polygon
p.round_corners(ri, ro, n)
(p2, ri2, ro2, n2) = p.extract_rad
# -> p2 == p, ro2 == ro, ri2 == ri, n2 == n (within some limits)
```

This method was introduced in version 0.25.

from_ipoly

Signature: *[static]* new DSimplePolygon ptr **from_ipoly** (const SimplePolygon polygon)

Description: Creates a floating-point coordinate polygon from an integer coordinate polygon

Use of this method is deprecated. Use new instead

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_ipoly'.

Python specific notes:
This method is the default initializer of the object.

from_s

Signature: *[static]* new DSimplePolygon ptr **from_s** (string s)

Description: Creates an object from a string

Creates the object from a string representation (as returned by to_s)

This method has been added in version 0.23.

hash

Signature: *[const]* unsigned long **hash**

Description: Computes a hash value

Returns a hash value for the given polygon. This method enables polygons as hash keys.

This method has been introduced in version 0.25.

Python specific notes:
This method is also available as 'hash(object)'.

inside?

Signature: *[const]* bool **inside?** (DPoint p)

Description: Gets a value indicating whether the given point is inside the polygon

If the given point is inside or on the edge the polygon, true is returned. This tests works well only if the polygon is not self-overlapping and oriented clockwise.

is_box?

Signature: *[const]* bool **is_box?**

Description: Returns a value indicating whether the polygon is a simple box.

Returns: True if the polygon is a box.

A polygon is a box if it is identical to its bounding box.

This method was introduced in version 0.23.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_empty?

Signature: *[const]* bool **is_empty?**

Description: Returns a value indicating whether the polygon is empty

is_halfmanhattan?

Signature: *[const]* bool **is_halfmanhattan?**

Description: Returns a value indicating whether the polygon is half-manhattan

Half-manhattan polygons have edges which are multiples of 45 degree. These polygons can be clipped at a rectangle without potential grid snapping.

This predicate was introduced in version 0.27.

is_rectilinear?

Signature: *[const]* bool **is_rectilinear?**

Description: Returns a value indicating whether the polygon is rectilinear

move

(1) Signature: DSimplePolygon **move** (const DVector p)

Description: Moves the simple polygon.

p: The distance to move the simple polygon.

Returns: The moved simple polygon.

Moves the simple polygon by the given offset and returns the moved simple polygon. The polygon is overwritten.

(2) Signature: DSimplePolygon **move** (double x, double y)

Description: Moves the polygon.

x: The x distance to move the polygon.

y: The y distance to move the polygon.

Returns: The moved polygon (self).

Moves the polygon by the given offset and returns the moved polygon. The polygon is overwritten.

moved

(1) Signature: *[const]* DSimplePolygon **moved** (const DVector p)

Description: Returns the moved simple polygon

p: The distance to move the simple polygon.

Returns: The moved simple polygon.

Moves the simple polygon by the given offset and returns the moved simple polygon. The polygon is not modified.

(2) Signature: *[const]* DSimplePolygon **moved** (double x, double y)

Description: Returns the moved polygon (does not modify self)

x: The x distance to move the polygon.

y: The y distance to move the polygon.

Returns: The moved polygon.

Moves the polygon by the given offset and returns the moved polygon. The polygon is not modified.

This method has been introduced in version 0.23.

new

(1) Signature: *[static]* new DSimplePolygon ptr **new** (const SimplePolygon polygon)

Description: Creates a floating-point coordinate polygon from an integer coordinate polygon

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_ipoly'.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new DSimplePolygon ptr **new**

Description: Default constructor: creates an empty (invalid) polygon

Python specific notes:

This method is the default initializer of the object.

(3) Signature: *[static]* new DSimplePolygon ptr **new** (DPoint[] pts, bool raw = false)

Description: Constructor given the points of the simple polygon

pts:	The points forming the simple polygon
raw:	If true, the points are taken as they are (see below)

If the 'raw' argument is set to true, the points are taken as they are. Specifically no removal of redundant points or joining of coincident edges will take place. In effect, polygons consisting of a single point or two points can be constructed as well as polygons with duplicate points. Note that such polygons may cause problems in some applications.

Regardless of raw mode, the point list will be adjusted such that the first point is the lowest-leftmost one and the orientation is clockwise always.

The 'raw' argument has been added in version 0.24.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new DSimplePolygon ptr **new** (const DBox box)

Description: Constructor converting a box to a polygon

box:	The box to convert to a polygon

Python specific notes:
This method is the default initializer of the object.

num_points

Signature: *[const]* unsigned long **num_points**

Description: Gets the number of points

perimeter

Signature: *[const]* double **perimeter**

Description: Gets the perimeter of the polygon

The perimeter is sum of the lengths of all edges making up the polygon.

point

Signature: *[const]* DPoint **point** (unsigned long p)

Description: Gets a specific point of the contour@param p The index of the point to get

If the index of the point is not a valid index, a default value is returned. This method was introduced in version 0.18.

points=

Signature: void **points=** (DPoint[] pts)

Description: Sets the points of the simple polygon

pts:	An array of points to assign to the simple polygon

See the constructor description for details about raw mode.

Python specific notes:
The object exposes a writable attribute 'points'. This is the setter.

round_corners

Signature: *[const]* DSimplePolygon **round_corners** (double rinner, double router, unsigned int n)

Description: Rounds the corners of the polygon

rinner:	The circle radius of inner corners (in database units).
router:	The circle radius of outer corners (in database units).

n: The number of points per full circle.

Returns: The new polygon.

Replaces the corners of the polygon with circle segments.

This method was introduced in version 0.22 for integer coordinates and in 0.25 for all coordinate types.

set_points

Signature: void **set_points** (DPoint[] pts, bool raw = false)

Description: Sets the points of the simple polygon

pts: An array of points to assign to the simple polygon

raw: If true, the points are taken as they are

See the constructor description for details about raw mode.

This method has been added in version 0.24.

split

Signature: *[const]* DSimplePolygon[] **split**

Description: Splits the polygon into two or more parts

This method will break the polygon into parts. The exact breaking algorithm is unspecified, the result are smaller polygons of roughly equal number of points and 'less concave' nature. Usually the returned polygon set consists of two polygons, but there can be more. The merged region of the resulting polygons equals the original polygon with the exception of small snapping effects at new vertexes.

The intended use for this method is a iteratively split polygons until the satisfy some maximum number of points limit.

This method has been introduced in version 0.25.3.

to_itype

Signature: *[const]* SimplePolygon **to_itype** (double dbu = 1)

Description: Converts the polygon to an integer coordinate polygon

The database unit can be specified to translate the floating-point coordinate polygon in micron units to an integer-coordinate polygon in database units. The polygon's' coordinates will be divided by the database unit.

This method has been introduced in version 0.25.

to_s

Signature: *[const]* string **to_s**

Description: Returns a string representing the polygon

Python specific notes:
This method is also available as 'str(object)'.

touches?

(1) Signature: *[const]* bool **touches?** (const DBox box)

Description: Returns true, if the polygon touches the given box.

The box and the polygon touch if they overlap or their contours share at least one point.

This method was introduced in version 0.25.1.

(2) Signature: *[const]* bool **touches?** (const DEdge edge)

Description: Returns true, if the polygon touches the given edge.

The edge and the polygon touch if they overlap or the edge shares at least one point with the polygon's contour.

This method was introduced in version 0.25.1.

(3) Signature: *[const]* bool **touches?** (const DPolygon polygon)

Description: Returns true, if the polygon touches the other polygon.

The polygons touch if they overlap or their contours share at least one point.

This method was introduced in version 0.25.1.

(4) Signature: *[const]* bool **touches?** (const DSimplePolygon simple_polygon)

Description: Returns true, if the polygon touches the other polygon.

The polygons touch if they overlap or their contours share at least one point.

This method was introduced in version 0.25.1.

transform

(1) Signature: DSimplePolygon ptr **transform** (const DCplxTrans t)

Description: Transforms the simple polygon with a complex transformation (in-place)

t: The transformation to apply.

Transforms the simple polygon with the given complex transformation. Modifies self and returns self. An out-of-place version which does not modify self is transformed.

This method has been introduced in version 0.24.

(2) Signature: DSimplePolygon ptr **transform** (const DTrans t)

Description: Transforms the simple polygon (in-place)

t: The transformation to apply.

Transforms the simple polygon with the given transformation. Modifies self and returns self. An out-of-place version which does not modify self is transformed.

This method has been introduced in version 0.24.

transformed

(1) Signature: *[const]* SimplePolygon **transformed** (const VCplxTrans t)

Description: Transforms the polygon with the given complex transformation

t: The magnifying transformation to apply

Returns: The transformed polygon (in this case an integer coordinate polygon)

This method has been introduced in version 0.25.

(2) Signature: *[const]* DSimplePolygon **transformed** (const DTrans t)

Description: Transforms the simple polygon.

t: The transformation to apply.

Returns: The transformed simple polygon.

Transforms the simple polygon with the given transformation. Does not modify the simple polygon but returns the transformed polygon.

(3) Signature: *[const]* DSimplePolygon **transformed** (const DCplxTrans t)

Description: Transforms the simple polygon.

t: The transformation to apply.

Returns: The transformed simple polygon.

Transforms the simple polygon with the given complex transformation. Does not modify the simple polygon but returns the transformed polygon.

With version 0.25, the original 'transformed_cplx' method is deprecated and 'transformed' takes both simple and complex transformations.

transformed_cplx

Signature: *[const]* DSimplePolygon **transformed_cplx** (const DCplxTrans t)

Description: Transforms the simple polygon.

t:	The transformation to apply.
Returns:	The transformed simple polygon.

Use of this method is deprecated. Use transformed instead

Transforms the simple polygon with the given complex transformation. Does not modify the simple polygon but returns the transformed polygon.

With version 0.25, the original 'transformed_cplx' method is deprecated and 'transformed' takes both simple and complex transformations.

4.76. API reference - Class Polygon

Notation used in Ruby API documentation

Module: db

Description: A polygon class

A polygon consists of an outer hull and zero to many holes. Each contour consists of several points. The point list is normalized such that the leftmost, lowest point is the first one. The orientation is normalized such that the orientation of the hull contour is clockwise, while the orientation of the holes is counterclockwise.

It is in no way checked that the contours are not overlapping. This must be ensured by the user of the object when filling the contours.

A polygon can be asked for the number of holes using the holes method. each_point_hull delivers the points of the hull contour. each_point_hole delivers the points of a specific hole. each_edge delivers the edges (point-to-point connections) of both hull and holes. bbox delivers the bounding box, area the area and perimeter the perimeter of the polygon.

Here's an example of how to create a polygon:

```
hull =  [ RBA::Point::new(0, 0),       RBA::Point::new(6000, 0),
          RBA::Point::new(6000, 3000), RBA::Point::new(0, 3000) ]
hole1 = [ RBA::Point::new(1000, 1000), RBA::Point::new(2000, 1000),
          RBA::Point::new(2000, 2000), RBA::Point::new(1000, 2000) ]
hole2 = [ RBA::Point::new(3000, 1000), RBA::Point::new(4000, 1000),
          RBA::Point::new(4000, 2000), RBA::Point::new(3000, 2000) ]
poly = RBA::Polygon::new(hull)
poly.insert_hole(hole1)
poly.insert_hole(hole2)

# ask the polygon for some properties
poly.holes      # -> 2
poly.area       # -> 16000000
poly.perimeter  # -> 26000
poly.bbox       # -> (0,0;6000,3000)
```

The Polygon class stores coordinates in integer format. A class that stores floating-point coordinates is DPolygon.

See The Database API for more details about the database objects.

Public constructors

new Polygon ptr	**new**	(const DPolygon dpolygon)	Creates an integer coordinate polygon from a floating-point coordinate polygon
new Polygon ptr	**new**		Creates an empty (invalid) polygon
new Polygon ptr	**new**	(const SimplePolygon sp)	Creates a polygon from a simple polygon
new Polygon ptr	**new**	(Point[] pts, bool raw = false)	Creates a polygon from a point array for the hull
new Polygon ptr	**new**	(const Box box)	Creates a polygon from a box

Public methods

[const]	bool	**!=**	(const Polygon p)	Returns a value indicating whether the polygons are not equal
[const]	Polygon	*****	(double f)	Scales the polygon by some factor

[const]	bool	**<**	(const Polygon p)	Returns a value indicating whether self is less than p
[const]	bool	**==**	(const Polygon p)	Returns a value indicating whether the polygons are equal
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	long	**area**		Gets the area of the polygon
[const]	long	**area2**		Gets the double area of the polygon
	void	**assign**	(const Polygon other)	Assigns another object to self
	void	**assign_hole**	(unsigned int n, Point[] p, bool raw = false)	Sets the points of the given hole of the polygon
	void	**assign_hole**	(unsigned int n, const Box b)	Sets the box as the given hole of the polygon
	void	**assign_hull**	(Point[] p, bool raw = false)	Sets the points of the hull of polygon
[const]	Box	**bbox**		Returns the bounding box of the polygon
[const]	Polygon[]	**break**	(unsigned long max_vertex_count, double max_area_ratio)	Splits the polygon into parts with a maximum vertex count and area ratio
	void	**compress**	(bool remove_reflected)	Compresses the polygon.
[const]	SimplePolygon[]	**decompose_convex**	(int preferred_orientation = PO_any)	Decomposes the polygon into convex pieces
[const]	SimplePolygon[]	**decompose_trapezoi**	(int mode = TD_simple)	Decomposes the polygon into trapezoids
[const]	new Polygon ptr	**dup**		Creates a copy of self
[const,iter]	Edge	**each_edge**		Iterates over the edges that make up the polygon

[const,iter]	Edge	**each_edge**	(unsigned int contour)	Iterates over the edges of one contour of the polygon
[const,iter]	Point	**each_point_hole**	(unsigned int n)	Iterates over the points that make up the nth hole
[const,iter]	Point	**each_point_hull**		Iterates over the points that make up the hull
[const]	variant[]	**extract_rad**		Extracts the corner radii from a rounded polygon
[const]	unsigned long	**hash**		Computes a hash value
[const]	unsigned int	**holes**		Returns the number of holes
	void	**hull=**	(Point[] p)	Sets the points of the hull of polygon
	void	**insert_hole**	(Point[] p, bool raw = false)	Inserts a hole with the given points
	void	**insert_hole**	(const Box b)	Inserts a hole from the given box
[const]	bool	**inside?**	(Point p)	Tests, if the given point is inside the polygon
[const]	bool	**is_box?**		Returns true, if the polygon is a simple box.
[const]	bool	**is_convex?**		Returns a value indicating whether the polygon is convex
[const]	bool	**is_empty?**		Returns a value indicating whether the polygon is empty
[const]	bool	**is_halfmanhattan?**		Returns a value indicating whether the polygon is half-manhattan
[const]	bool	**is_rectilinear?**		Returns a value indicating whether the polygon is rectilinear
[const]	Polygon	**minkowski_sum**	(const Edge e, bool resolve_holes)	Computes the Minkowski sum of the polygon and an edge
[const]	Polygon	**minkowski_sum**	(const Polygon b, bool resolve_holes)	Computes the Minkowski sum of the polygon and a polygon
[const]	Polygon	**minkowski_sum**	(const Box b, bool resolve_holes)	Computes the Minkowski sum of the polygon and a box
[const]	Polygon	**minkowski_sum**	(Point[] b, bool resolve_holes)	Computes the Minkowski sum of the polygon and a contour of points (a trace)
	Polygon	**move**	(const Vector p)	Moves the polygon.
	Polygon	**move**	(int x, int y)	Moves the polygon.

[const]	Polygon	**moved**	(const Vector p)	Returns the moved polygon (does not modify self)
[const]	Polygon	**moved**	(int x, int y)	Returns the moved polygon (does not modify self)
[const]	unsigned long	**num_points**		Gets the total number of points (hull plus holes)
[const]	unsigned long	**num_points_hole**	(unsigned int n)	Gets the number of points of the given hole
[const]	unsigned long	**num_points_hull**		Gets the number of points of the hull
[const]	unsigned long	**perimeter**		Gets the perimeter of the polygon
[const]	Point	**point_hole**	(unsigned int n, unsigned long p)	Gets a specific point of a hole
[const]	Point	**point_hull**	(unsigned long p)	Gets a specific point of the hull
	void	**resolve_holes**		Resolve holes by inserting cut lines and joining the holes with the hull
[const]	Polygon	**resolved_holes**		Returns a polygon without holes
[const]	Polygon	**round_corners**	(double rinner, double router, unsigned int n)	Rounds the corners of the polygon
	void	**size**	(int dx, int dy, unsigned int mode)	Sizes the polygon (biasing)
	void	**size**	(const Vector dv, unsigned int mode = 2)	Sizes the polygon (biasing)
	void	**size**	(int d, unsigned int mode = 2)	Sizes the polygon (biasing)
[const]	Polygon	**sized**	(int dx, int dy, unsigned int mode)	Sizes the polygon (biasing) without modifying self
[const]	Polygon	**sized**	(const Vector dv, unsigned int mode = 2)	Sizes the polygon (biasing) without modifying self
[const]	Polygon	**sized**	(int d, unsigned int mode = 2)	Sizes the polygon (biasing) without modifying self
[const]	Polygon	**smooth**	(int d, bool keep_hv = false)	Smooths a polygon
	void	**sort_holes**		Brings the holes in a specific order

[const]	Polygon[]	**split**		Splits the polygon into two or more parts
[const]	DPolygon	**to_dtype**	(double dbu = 1)	Converts the polygon to a floating-point coordinate polygon
[const]	string	**to_s**		Returns a string representing the polygon
[const]	SimplePolygon	**to_simple_polygon**		Converts a polygon to a simple polygon
[const]	bool	**touches?**	(const Box box)	Returns true, if the polygon touches the given box.
[const]	bool	**touches?**	(const Edge edge)	Returns true, if the polygon touches the given edge.
[const]	bool	**touches?**	(const Polygon polygon)	Returns true, if the polygon touches the other polygon.
[const]	bool	**touches?**	(const SimplePolygon simple_polygon)	Returns true, if the polygon touches the other polygon.
	Polygon ptr	**transform**	(const ICplxTrans t)	Transforms the polygon with a complex transformation (in-place)
	Polygon ptr	**transform**	(const Trans t)	Transforms the polygon (in-place)
[const]	Polygon	**transformed**	(const Trans t)	Transforms the polygon
[const]	DPolygon	**transformed**	(const CplxTrans t)	Transforms the polygon with a complex transformation

Public static methods and constants

[static,const]	int	**PO_any**	A value for the preferred orientation parameter of decompose_convex
[static,const]	int	**PO_horizontal**	A value for the preferred orientation parameter of decompose_convex
[static,const]	int	**PO_htrapezoids**	A value for the preferred orientation parameter of decompose_convex
[static,const]	int	**PO_vertical**	A value for the preferred orientation parameter of decompose_convex
[static,const]	int	**PO_vtrapezoids**	A value for the preferred orientation parameter of decompose_convex
[static,const]	int	**TD_htrapezoids**	A value for the mode parameter of decompose_trapezoids
[static,const]	int	**TD_simple**	A value for the mode parameter of decompose_trapezoids
[static,const]	int	**TD_vtrapezoids**	A value for the mode parameter of decompose_trapezoids

	new Polygon ptr	**ellipse**	(const Box box, int n)	Creates a simple polygon approximating an ellipse
	new Polygon ptr	**from_s**	(string s)	Creates a polygon from a string

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**		Use of this method is deprecated. Use _create instead
	void	**destroy**		Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**		Use of this method is deprecated. Use _destroyed? instead
[static]	new Polygon ptr	**from_dpoly**	(const DPolygon dpolygon)	Use of this method is deprecated. Use new instead

[const]	Polygon	**minkowsky_sum**	(const Polygon b, bool resolve_holes)	Use of this method is deprecated. Use minkowski_sum instead
[const]	Polygon	**minkowsky_sum**	(const Box b, bool resolve_holes)	Use of this method is deprecated. Use minkowski_sum instead
[const]	Polygon	**minkowsky_sum**	(Point[] b, bool resolve_holes)	Use of this method is deprecated. Use minkowski_sum instead
[const]	Polygon	**transformed**	(const ICplxTrans t)	Use of this method is deprecated
[const]	DPolygon	**transformed_cplx**	(const CplxTrans t)	Use of this method is deprecated. Use transformed instead

Detailed description

!=

Signature: *[const]* bool **!=** (const Polygon p)

Description: Returns a value indicating whether the polygons are not equal

p: The object to compare against

*****

Signature: *[const]* Polygon ***** (double f)

Description: Scales the polygon by some factor

Returns the scaled object. All coordinates are multiplied with the given factor and if necessary rounded.

Python specific notes:

This method also implements '__rmul__'.

<	**Signature**: *[const]* bool **<** (const Polygon p) **Description**: Returns a value indicating whether self is less than p **p**: The object to compare against This operator is provided to establish some, not necessarily a certain sorting order
==	**Signature**: *[const]* bool **==** (const Polygon p) **Description**: Returns a value indicating whether the polygons are equal **p**: The object to compare against
PO_any	**Signature**: *[static,const]* int **PO_any** **Description**: A value for the preferred orientation parameter of decompose_convex This value indicates that there is not cut preference This constant has been introduced in version 0.25. **Python specific notes:** The object exposes a readable attribute 'PO_any'. This is the getter.
PO_horizontal	**Signature**: *[static,const]* int **PO_horizontal** **Description**: A value for the preferred orientation parameter of decompose_convex This value indicates that there only horizontal cuts are allowed This constant has been introduced in version 0.25. **Python specific notes:** The object exposes a readable attribute 'PO_horizontal'. This is the getter.
PO_htrapezoids	**Signature**: *[static,const]* int **PO_htrapezoids** **Description**: A value for the preferred orientation parameter of decompose_convex This value indicates that cuts shall favor decomposition into horizontal trapezoids This constant has been introduced in version 0.25. **Python specific notes:** The object exposes a readable attribute 'PO_htrapezoids'. This is the getter.
PO_vertical	**Signature**: *[static,const]* int **PO_vertical** **Description**: A value for the preferred orientation parameter of decompose_convex This value indicates that there only vertical cuts are allowed This constant has been introduced in version 0.25. **Python specific notes:** The object exposes a readable attribute 'PO_vertical'. This is the getter.
PO_vtrapezoids	**Signature**: *[static,const]* int **PO_vtrapezoids** **Description**: A value for the preferred orientation parameter of decompose_convex This value indicates that cuts shall favor decomposition into vertical trapezoids This constant has been introduced in version 0.25. **Python specific notes:** The object exposes a readable attribute 'PO_vtrapezoids'. This is the getter.

TD_htrapezoids

Signature: *[static,const]* int **TD_htrapezoids**

Description: A value for the mode parameter of decompose_trapezoids

This value indicates simple decomposition mode. This mode produces horizontal trapezoids and tries to minimize the number of trapezoids. This constant has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'TD_htrapezoids'. This is the getter.

TD_simple

Signature: *[static,const]* int **TD_simple**

Description: A value for the mode parameter of decompose_trapezoids

This value indicates simple decomposition mode. This mode is fast but does not make any attempts to produce less trapezoids. This constant has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'TD_simple'. This is the getter.

TD_vtrapezoids

Signature: *[static,const]* int **TD_vtrapezoids**

Description: A value for the mode parameter of decompose_trapezoids

This value indicates simple decomposition mode. This mode produces vertical trapezoids and tries to minimize the number of trapezoids.

Python specific notes:
The object exposes a readable attribute 'TD_vtrapezoids'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is

known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

area

Signature: *[const]* long **area**

Description: Gets the area of the polygon

The area is correct only if the polygon is not self-overlapping and the polygon is oriented clockwise.Orientation is ensured automatically in most cases.

area2

Signature: *[const]* long **area2**

Description: Gets the double area of the polygon

This method is provided because the area for an integer-type polygon is a multiple of 1/2. Hence the double area can be expresses precisely as an integer for these types.

This method has been introduced in version 0.26.1

assign

Signature: void **assign** (const Polygon other)

Description: Assigns another object to self

assign_hole

(1) Signature: void **assign_hole** (unsigned int n, Point[] p, bool raw = false)

Description: Sets the points of the given hole of the polygon

n: The index of the hole to which the points should be assigned

p: An array of points to assign to the polygon's hole

raw: If true, the points won't be compressed (see assign_hull)

If the hole index is not valid, this method does nothing.

This method was introduced in version 0.18. The 'raw' argument was added in version 0.24.

(2) Signature: void **assign_hole** (unsigned int n, const Box b)

Description: Sets the box as the given hole of the polygon

n: The index of the hole to which the points should be assigned

b: The box to assign to the polygon's hole

If the hole index is not valid, this method does nothing. This method was introduced in version 0.23.

assign_hull

Signature: void **assign_hull** (Point[] p, bool raw = false)

Description: Sets the points of the hull of polygon

p: An array of points to assign to the polygon's hull

raw: If true, the points won't be compressed

If the 'raw' argument is set to true, the points are taken as they are. Specifically no removal of redundant points or joining of coincident edges will take place. In effect, polygons consisting of a single point or two points can be constructed as well as polygons with duplicate points. Note that such polygons may cause problems in some applications.

Regardless of raw mode, the point list will be adjusted such that the first point is the lowest-leftmost one and the orientation is clockwise always.

The 'assign_hull' variant is provided in analogy to 'assign_hole'.

The 'raw' argument was added in version 0.24.

bbox

Signature: *[const]* Box **bbox**

Description: Returns the bounding box of the polygon

The bounding box is the box enclosing all points of the polygon.

break

Signature: *[const]* Polygon[] **break** (unsigned long max_vertex_count, double max_area_ratio)

Description: Splits the polygon into parts with a maximum vertex count and area ratio

The area ratio is the ratio between the bounding box area and the polygon area. Higher values mean more 'skinny' polygons.

This method will split the input polygon into pieces having a maximum of 'max_vertex_count' vertices and an area ratio less than 'max_area_ratio'. 'max_vertex_count' can be zero. In this case the limit is ignored. Also 'max_area_ratio' can be zero, in which case it is ignored as well.

The method of splitting is unspecified. The algorithm will apply 'split' recursively until the parts satisfy the limits.

This method has been introduced in version 0.29.

Python specific notes:
This attribute is available as 'break_' in Python.

compress

Signature: void **compress** (bool remove_reflected)

Description: Compresses the polygon.

remove_reflected: See description of the functionality.

This method removes redundant points from the polygon, such as points being on a line formed by two other points. If remove_reflected is true, points are also removed if the two adjacent edges form a spike.

This method was introduced in version 0.18.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

decompose_convex

Signature: *[const]* SimplePolygon[] **decompose_convex** (int preferred_orientation = PO_any)

Description: Decomposes the polygon into convex pieces

preferred_orientation: One of the PO_... constants

This method returns a decomposition of the polygon that contains convex pieces only. If the polygon was convex already, the list returned has a single element which is the original polygon.

This method was introduced in version 0.25.

decompose_trapezoids

Signature: *[const]* SimplePolygon[] **decompose_trapezoids** (int mode = TD_simple)

Description: Decomposes the polygon into trapezoids

mode: One of the TD_... constants

This method returns a decomposition of the polygon into trapezoid pieces. It supports different modes for various applications. See the TD_... constants for details.

This method was introduced in version 0.25.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new Polygon ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

each_edge

(1) Signature: *[const,iter]* Edge **each_edge**

Description: Iterates over the edges that make up the polygon

This iterator will deliver all edges, including those of the holes. Hole edges are oriented counterclockwise while hull edges are oriented clockwise.

(2) Signature: *[const,iter]* Edge **each_edge** (unsigned int contour)

Description: Iterates over the edges of one contour of the polygon

contour: The contour number (0 for hull, 1 for first hole ...)

This iterator will deliver all edges of the contour specified by the contour parameter. The hull has contour number 0, the first hole has contour 1 etc. Hole edges are oriented counterclockwise while hull edges are oriented clockwise.

This method was introduced in version 0.24.

each_point_hole

Signature: *[const,iter]* Point **each_point_hole** (unsigned int n)

Description: Iterates over the points that make up the nth hole

The hole number must be less than the number of holes (see holes)

each_point_hull

Signature: *[const,iter]* Point **each_point_hull**

Description: Iterates over the points that make up the hull

ellipse

Signature: *[static]* new Polygon ptr **ellipse** (const Box box, int n)

Description: Creates a simple polygon approximating an ellipse

box: The bounding box of the ellipse

n: The number of points that will be used to approximate the ellipse

This method has been introduced in version 0.23.

extract_rad

Signature: *[const]* variant[] **extract_rad**

Description: Extracts the corner radii from a rounded polygon

Attempts to extract the radii of rounded corner polygon. This is essentially the inverse of the round_corners method. If this method succeeds, if will return an array of four elements:

- The polygon with the rounded corners replaced by edgy ones
- The radius of the inner corners
- The radius of the outer corners
- The number of points per full circle

This method is based on some assumptions and may fail. In this case, an empty array is returned.

If successful, the following code will more or less render the original polygon and parameters

```
p = ...   # some polygon
p.round_corners(ri, ro, n)
(p2, ri2, ro2, n2) = p.extract_rad
# -> p2 == p, ro2 == ro, ri2 == ri, n2 == n (within some limits)
```

This method was introduced in version 0.25.

from_dpoly

Signature: *[static]* new Polygon ptr **from_dpoly** (const DPolygon dpolygon)

Description: Creates an integer coordinate polygon from a floating-point coordinate polygon

Use of this method is deprecated. Use new instead

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_dpolygon'.

Python specific notes:
This method is the default initializer of the object.

from_s

Signature: *[static]* new Polygon ptr **from_s** (string s)

Description: Creates a polygon from a string

Creates the object from a string representation (as returned by to_s)

This method has been added in version 0.23.

hash

Signature: *[const]* unsigned long **hash**

Description: Computes a hash value

Returns a hash value for the given polygon. This method enables polygons as hash keys.

This method has been introduced in version 0.25.

Python specific notes:
This method is also available as 'hash(object)'.

holes

Signature: *[const]* unsigned int **holes**

Description: Returns the number of holes

hull=

Signature: void **hull=** (Point[] p)

Description: Sets the points of the hull of polygon

p: An array of points to assign to the polygon's hull

The 'assign_hull' variant is provided in analogy to 'assign_hole'.

Python specific notes:
The object exposes a writable attribute 'hull'. This is the setter.

insert_hole

(1) Signature: void **insert_hole** (Point[] p, bool raw = false)

Description: Inserts a hole with the given points

p: An array of points to insert as a new hole

raw: If true, the points won't be compressed (see assign_hull)

The 'raw' argument was added in version 0.24.

(2) Signature: void **insert_hole** (const Box b)

Description: Inserts a hole from the given box

b: The box to insert as a new hole

This method was introduced in version 0.23.

inside?

Signature: *[const]* bool **inside?** (Point p)

Description: Tests, if the given point is inside the polygon

If the given point is inside or on the edge of the polygon, true is returned. This tests works well only if the polygon is not self-overlapping and oriented clockwise.

is_box?

Signature: *[const]* bool **is_box?**

Description: Returns true, if the polygon is a simple box.

Returns: True if the polygon is a box.

A polygon is a box if it is identical to its bounding box.

This method was introduced in version 0.23.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_convex?

Signature: *[const]* bool **is_convex?**

Description: Returns a value indicating whether the polygon is convex

This method will return true, if the polygon is convex.

This method was introduced in version 0.25.

is_empty?

Signature: *[const]* bool **is_empty?**

Description: Returns a value indicating whether the polygon is empty

is_halfmanhattan?

Signature: *[const]* bool **is_halfmanhattan?**

Description: Returns a value indicating whether the polygon is half-manhattan

Half-manhattan polygons have edges which are multiples of 45 degree. These polygons can be clipped at a rectangle without potential grid snapping.

This predicate was introduced in version 0.27.

is_rectilinear?

Signature: *[const]* bool **is_rectilinear?**

Description: Returns a value indicating whether the polygon is rectilinear

minkowski_sum

(1) Signature: *[const]* Polygon **minkowski_sum** (const Edge e, bool resolve_holes)

Description: Computes the Minkowski sum of the polygon and an edge

e:	The edge.
resolve_holes:	If true, the output polygon will not contain holes, but holes are resolved by joining the holes with the hull.
Returns:	The new polygon representing the Minkowski sum with the edge e.

The Minkowski sum of a polygon and an edge basically results in the area covered when "dragging" the polygon along the line given by the edge. The effect is similar to drawing the line with a pencil that has the shape of the given polygon.

This method was introduced in version 0.22.

(2) Signature: *[const]* Polygon **minkowski_sum** (const Polygon b, bool resolve_holes)

Description: Computes the Minkowski sum of the polygon and a polygon

p:	The first argument.
resolve_holes:	If true, the output polygon will not contain holes, but holes are resolved by joining the holes with the hull.
Returns:	The new polygon representing the Minkowski sum of self and p.

This method was introduced in version 0.22.

(3) Signature: *[const]* Polygon **minkowski_sum** (const Box b, bool resolve_holes)

Description: Computes the Minkowski sum of the polygon and a box

b:	The box.
resolve_holes:	If true, the output polygon will not contain holes, but holes are resolved by joining the holes with the hull.
Returns:	The new polygon representing the Minkowski sum of self and the box.

This method was introduced in version 0.22.

(4) Signature: *[const]* Polygon **minkowski_sum** (Point[] b, bool resolve_holes)

Description: Computes the Minkowski sum of the polygon and a contour of points (a trace)

b:	The contour (a series of points forming the trace).
resolve_holes:	If true, the output polygon will not contain holes, but holes are resolved by joining the holes with the hull.
Returns:	The new polygon representing the Minkowski sum of self and the contour.

This method was introduced in version 0.22.

minkowsky_sum

(1) Signature: *[const]* Polygon **minkowsky_sum** (const Edge e, bool resolve_holes)

Description: Computes the Minkowski sum of the polygon and an edge

e:	The edge.
resolve_holes:	If true, the output polygon will not contain holes, but holes are resolved by joining the holes with the hull.
Returns:	The new polygon representing the Minkowski sum with the edge e.

Use of this method is deprecated. Use minkowski_sum instead

The Minkowski sum of a polygon and an edge basically results in the area covered when "dragging" the polygon along the line given by the edge. The effect is similar to drawing the line with a pencil that has the shape of the given polygon.

This method was introduced in version 0.22.

(2) Signature: *[const]* Polygon **minkowsky_sum** (const Polygon b, bool resolve_holes)

Description: Computes the Minkowski sum of the polygon and a polygon

p:	The first argument.
resolve_holes:	If true, the output polygon will not contain holes, but holes are resolved by joining the holes with the hull.
Returns:	The new polygon representing the Minkowski sum of self and p.

Use of this method is deprecated. Use minkowski_sum instead

This method was introduced in version 0.22.

(3) Signature: *[const]* Polygon **minkowsky_sum** (const Box b, bool resolve_holes)

Description: Computes the Minkowski sum of the polygon and a box

b:	The box.
resolve_holes:	If true, the output polygon will not contain holes, but holes are resolved by joining the holes with the hull.
Returns:	The new polygon representing the Minkowski sum of self and the box.

Use of this method is deprecated. Use minkowski_sum instead

This method was introduced in version 0.22.

(4) Signature: *[const]* Polygon **minkowsky_sum** (Point[] b, bool resolve_holes)

Description: Computes the Minkowski sum of the polygon and a contour of points (a trace)

b:	The contour (a series of points forming the trace).
resolve_holes:	If true, the output polygon will not contain holes, but holes are resolved by joining the holes with the hull.
Returns:	The new polygon representing the Minkowski sum of self and the contour.

Use of this method is deprecated. Use minkowski_sum instead

This method was introduced in version 0.22.

move

(1) Signature: Polygon **move** (const Vector p)

Description: Moves the polygon.

p:	The distance to move the polygon.
Returns:	The moved polygon (self).

Moves the polygon by the given offset and returns the moved polygon. The polygon is overwritten.

This method has been introduced in version 0.23.

(2) Signature: Polygon **move** (int x, int y)

Description: Moves the polygon.

x:	The x distance to move the polygon.
y:	The y distance to move the polygon.
Returns:	The moved polygon (self).

Moves the polygon by the given offset and returns the moved polygon. The polygon is overwritten.

moved

(1) Signature: *[const]* Polygon **moved** (const Vector p)

Description: Returns the moved polygon (does not modify self)

p:	The distance to move the polygon.
Returns:	The moved polygon.

Moves the polygon by the given offset and returns the moved polygon. The polygon is not modified.

This method has been introduced in version 0.23.

(2) Signature: *[const]* Polygon **moved** (int x, int y)

Description: Returns the moved polygon (does not modify self)

x:	The x distance to move the polygon.
y:	The y distance to move the polygon.
Returns:	The moved polygon.

Moves the polygon by the given offset and returns the moved polygon. The polygon is not modified.

This method has been introduced in version 0.23.

new

(1) Signature: *[static]* new Polygon ptr **new** (const DPolygon dpolygon)

Description: Creates an integer coordinate polygon from a floating-point coordinate polygon

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_dpolygon'.

Python specific notes:

This method is the default initializer of the object.

(2) Signature: *[static]* new Polygon ptr **new**

Description: Creates an empty (invalid) polygon

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new Polygon ptr **new** (const SimplePolygon sp)

Description: Creates a polygon from a simple polygon

sp: The simple polygon that is converted into the polygon

This method was introduced in version 0.22.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new Polygon ptr **new** (Point[] pts, bool raw = false)

Description: Creates a polygon from a point array for the hull

pts: The points forming the polygon hull

raw: If true, the point list won't be modified (see assign_hull)

The 'raw' argument was added in version 0.24.

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new Polygon ptr **new** (const Box box)

Description: Creates a polygon from a box

box: The box to convert to a polygon

Python specific notes:
This method is the default initializer of the object.

num_points

Signature: *[const]* unsigned long **num_points**

Description: Gets the total number of points (hull plus holes)

This method was introduced in version 0.18.

num_points_hole

Signature: *[const]* unsigned long **num_points_hole** (unsigned int n)

Description: Gets the number of points of the given hole

The argument gives the index of the hole of which the number of points are requested. The index must be less than the number of holes (see holes).

num_points_hull

Signature: *[const]* unsigned long **num_points_hull**

Description: Gets the number of points of the hull

perimeter

Signature: *[const]* unsigned long **perimeter**

Description: Gets the perimeter of the polygon

The perimeter is sum of the lengths of all edges making up the polygon.

This method has been introduce in version 0.23.

point_hole

Signature: *[const]* Point **point_hole** (unsigned int n, unsigned long p)

Description: Gets a specific point of a hole

n: The index of the hole to which the points should be assigned

p: The index of the point to get

If the index of the point or of the hole is not valid, a default value is returned. This method was introduced in version 0.18.

point_hull

Signature: *[const]* Point **point_hull** (unsigned long p)

Description: Gets a specific point of the hull

p: The index of the point to get

If the index of the point is not a valid index, a default value is returned. This method was introduced in version 0.18.

resolve_holes

Signature: void **resolve_holes**

Description: Resolve holes by inserting cut lines and joining the holes with the hull

This method modifies the polygon. The out-of-place version is resolved_holes. This method was introduced in version 0.22.

resolved_holes

Signature: *[const]* Polygon **resolved_holes**

Description: Returns a polygon without holes

Returns: The new polygon without holes.

This method does not modify the polygon but return a new polygon. This method was introduced in version 0.22.

round_corners

Signature: *[const]* Polygon **round_corners** (double rinner, double router, unsigned int n)

Description: Rounds the corners of the polygon

rinner: The circle radius of inner corners (in database units).

router: The circle radius of outer corners (in database units).

n: The number of points per full circle.

Returns: The new polygon.

Replaces the corners of the polygon with circle segments.

This method was introduced in version 0.20 for integer coordinates and in 0.25 for all coordinate types.

size

(1) Signature: void **size** (int dx, int dy, unsigned int mode)

Description: Sizes the polygon (biasing)

Shifts the contour outwards (dx,dy>0) or inwards (dx,dy<0). dx is the sizing in x-direction and dy is the sizing in y-direction. The sign of dx and dy should be identical. The sizing operation create invalid (self-overlapping, reverse oriented) contours.

The mode defines at which bending angle cutoff occurs (0:>0, 1:>45, 2:>90, 3:>135, 4:>approx. 168, other:>approx. 179)

In order to obtain a proper polygon in the general case, the sized polygon must be merged in 'greater than zero' wrap count mode. This is necessary since in the general case, sizing can be complicated

operation which lets a single polygon fall apart into disjoint pieces for example. This can be achieved using the EdgeProcessor class for example:

```
poly = ... # a RBA::Polygon
poly.size(-50, 2)
ep = RBA::EdgeProcessor::new
# result is an array of RBA::Polygon objects
result = ep.simple_merge_p2p([ poly ], false, false, 1)
```

(2) Signature: void **size** (const Vector dv, unsigned int mode = 2)

Description: Sizes the polygon (biasing)

This method is equivalent to

```
size(dv.x, dv.y, mode)
```

See size for a detailed description.

This version has been introduced in version 0.28.

(3) Signature: void **size** (int d, unsigned int mode = 2)

Description: Sizes the polygon (biasing)

Shifts the contour outwards (d>0) or inwards (d<0). This method is equivalent to

```
size(d, d, mode)
```

See size for a detailed description.

This method has been introduced in version 0.23.

sized

(1) Signature: *[const]* Polygon **sized** (int dx, int dy, unsigned int mode)

Description: Sizes the polygon (biasing) without modifying self

This method applies sizing to the polygon but does not modify self. Instead a sized copy is returned. See size for a description of the operation.

This method has been introduced in version 0.23.

(2) Signature: *[const]* Polygon **sized** (const Vector dv, unsigned int mode = 2)

Description: Sizes the polygon (biasing) without modifying self

This method is equivalent to

```
sized(dv.x, dv.y, mode)
```

See size and sized for a detailed description.

This version has been introduced in version 0.28.

(3) Signature: *[const]* Polygon **sized** (int d, unsigned int mode = 2)

Description: Sizes the polygon (biasing) without modifying self

Shifts the contour outwards (d>0) or inwards (d<0). This method is equivalent to

```
sized(d, d, mode)
```

See size and sized for a detailed description.

smooth

Signature: *[const]* Polygon **smooth** (int d, bool keep_hv = false)

Description: Smooths a polygon

d:	The smoothing "roughness".
keep_hv:	If true, horizontal and vertical edges will be preserved always.
Returns:	The smoothed polygon.

Remove vertices that deviate by more than the distance d from the average contour. The value d is basically the roughness which is removed.

This method was introduced in version 0.23. The 'keep_hv' optional parameter was added in version 0.27.

sort_holes

Signature: void **sort_holes**

Description: Brings the holes in a specific order

This function is normalize the hole order so the comparison of two polygons does not depend on the order the holes were inserted. Polygons generated by KLayout's alorithms have their holes sorted.

This method has been introduced in version 0.28.8.

split

Signature: *[const]* Polygon[] **split**

Description: Splits the polygon into two or more parts

This method will break the polygon into parts. The exact breaking algorithm is unspecified, the result are smaller polygons of roughly equal number of points and 'less concave' nature. Usually the returned polygon set consists of two polygons, but there can be more. The merged region of the resulting polygons equals the original polygon with the exception of small snapping effects at new vertexes.

The intended use for this method is a iteratively split polygons until the satisfy some maximum number of points limit.

This method has been introduced in version 0.25.3.

to_dtype

Signature: *[const]* DPolygon **to_dtype** (double dbu = 1)

Description: Converts the polygon to a floating-point coordinate polygon

The database unit can be specified to translate the integer-coordinate polygon into a floating-point coordinate polygon in micron units. The database unit is basically a scaling factor.

This method has been introduced in version 0.25.

to_s

Signature: *[const]* string **to_s**

Description: Returns a string representing the polygon

Python specific notes:
This method is also available as 'str(object)'.

to_simple_polygon

Signature: *[const]* SimplePolygon **to_simple_polygon**

Description: Converts a polygon to a simple polygon

Returns: The simple polygon.

If the polygon contains holes, these will be resolved. This operation requires a well-formed polygon. Reflecting edges, self-intersections and coincident points will be removed.

This method was introduced in version 0.22.

touches?

(1) Signature: *[const]* bool **touches?** (const Box box)

Description: Returns true, if the polygon touches the given box.

The box and the polygon touch if they overlap or their contours share at least one point.

This method was introduced in version 0.25.1.

(2) Signature: *[const]* bool **touches?** (const Edge edge)

Description: Returns true, if the polygon touches the given edge.

The edge and the polygon touch if they overlap or the edge shares at least one point with the polygon's contour.

This method was introduced in version 0.25.1.

(3) Signature: *[const]* bool **touches?** (const Polygon polygon)

Description: Returns true, if the polygon touches the other polygon.

The polygons touch if they overlap or their contours share at least one point.

This method was introduced in version 0.25.1.

(4) Signature: *[const]* bool **touches?** (const SimplePolygon simple_polygon)

Description: Returns true, if the polygon touches the other polygon.

The polygons touch if they overlap or their contours share at least one point.

This method was introduced in version 0.25.1.

transform

(1) Signature: Polygon ptr **transform** (const ICplxTrans t)

Description: Transforms the polygon with a complex transformation (in-place)

t: The transformation to apply.

Transforms the polygon with the given complex transformation. This version modifies self and will return self as the modified polygon. An out-of-place version which does not modify self is transformed.

This method was introduced in version 0.24.

(2) Signature: Polygon ptr **transform** (const Trans t)

Description: Transforms the polygon (in-place)

t: The transformation to apply.

Transforms the polygon with the given transformation. Modifies self and returns self. An out-of-place version which does not modify self is transformed.

This method has been introduced in version 0.24.

transformed

(1) Signature: *[const]* Polygon **transformed** (const ICplxTrans t)

Description: Transforms the polygon with a complex transformation

t:	The transformation to apply.
Returns:	The transformed polygon (in this case an integer coordinate polygon).

Use of this method is deprecated

Transforms the polygon with the given complex transformation. Does not modify the polygon but returns the transformed polygon.

This method was introduced in version 0.18.

(2) Signature: *[const]* Polygon **transformed** (const Trans t)

Description: Transforms the polygon

t:	The transformation to apply.
Returns:	The transformed polygon.

Transforms the polygon with the given transformation. Does not modify the polygon but returns the transformed polygon.

(3) Signature: *[const]* DPolygon **transformed** (const CplxTrans t)

Description: Transforms the polygon with a complex transformation

t:	The transformation to apply.
Returns:	The transformed polygon.

Transforms the polygon with the given complex transformation. Does not modify the polygon but returns the transformed polygon.

With version 0.25, the original 'transformed_cplx' method is deprecated and 'transformed' takes both simple and complex transformations.

transformed_cplx

Signature: *[const]* DPolygon **transformed_cplx** (const CplxTrans t)

Description: Transforms the polygon with a complex transformation

t:	The transformation to apply.
Returns:	The transformed polygon.

Use of this method is deprecated. Use transformed instead

Transforms the polygon with the given complex transformation. Does not modify the polygon but returns the transformed polygon.

With version 0.25, the original 'transformed_cplx' method is deprecated and 'transformed' takes both simple and complex transformations.

4.77. API reference - Class DPolygon

Notation used in Ruby API documentation

Module: db

Description: A polygon class

A polygon consists of an outer hull and zero to many holes. Each contour consists of several points. The point list is normalized such that the leftmost, lowest point is the first one. The orientation is normalized such that the orientation of the hull contour is clockwise, while the orientation of the holes is counterclockwise.

It is in no way checked that the contours are not overlapping. This must be ensured by the user of the object when filling the contours.

A polygon can be asked for the number of holes using the holes method. each_point_hull delivers the points of the hull contour. each_point_hole delivers the points of a specific hole. each_edge delivers the edges (point-to-point connections) of both hull and holes. bbox delivers the bounding box, area the area and perimeter the perimeter of the polygon.

Here's an example of how to create a polygon:

```
hull =  [ RBA::DPoint::new(0, 0),       RBA::DPoint::new(6000, 0),
          RBA::DPoint::new(6000, 3000), RBA::DPoint::new(0, 3000) ]
hole1 = [ RBA::DPoint::new(1000, 1000), RBA::DPoint::new(2000, 1000),
          RBA::DPoint::new(2000, 2000), RBA::DPoint::new(1000, 2000) ]
hole2 = [ RBA::DPoint::new(3000, 1000), RBA::DPoint::new(4000, 1000),
          RBA::DPoint::new(4000, 2000), RBA::DPoint::new(3000, 2000) ]
poly = RBA::DPolygon::new(hull)
poly.insert_hole(hole1)
poly.insert_hole(hole2)

# ask the polygon for some properties
poly.holes      # -> 2
poly.area       # -> 16000000.0
poly.perimeter  # -> 26000.0
poly.bbox       # -> (0,0;6000,3000)
```

The DPolygon class stores coordinates in floating-point format which gives a higher precision for some operations. A class that stores integer coordinates is Polygon.

See The Database API for more details about the database objects.

Public constructors

new DPolygon ptr	**new**	(const Polygon polygon)	Creates a floating-point coordinate polygon from an integer coordinate polygon
new DPolygon ptr	**new**		Creates an empty (invalid) polygon
new DPolygon ptr	**new**	(const DSimplePolygon sp)	Creates a polygon from a simple polygon
new DPolygon ptr	**new**	(DPoint[] pts, bool raw = false)	Creates a polygon from a point array for the hull
new DPolygon ptr	**new**	(const DBox box)	Creates a polygon from a box

Public methods

[const]	bool	**!=**	(const DPolygon p)	Returns a value indicating whether the polygons are not equal

[const]	DPolygon	*****	(double f)	Scales the polygon by some factor
[const]	bool	**<**	(const DPolygon p)	Returns a value indicating whether self is less than p
[const]	bool	**==**	(const DPolygon p)	Returns a value indicating whether the polygons are equal
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	double	**area**		Gets the area of the polygon
[const]	double	**area2**		Gets the double area of the polygon
	void	**assign**	(const DPolygon other)	Assigns another object to self
	void	**assign_hole**	(unsigned int n, DPoint[] p, bool raw = false)	Sets the points of the given hole of the polygon
	void	**assign_hole**	(unsigned int n, const DBox b)	Sets the box as the given hole of the polygon
	void	**assign_hull**	(DPoint[] p, bool raw = false)	Sets the points of the hull of polygon
[const]	DBox	**bbox**		Returns the bounding box of the polygon
[const]	DPolygon[]	**break**	(unsigned long max_vertex_count, double max_area_ratio)	Splits the polygon into parts with a maximum vertex count and area ratio
	void	**compress**	(bool remove_reflected)	Compresses the polygon.
[const]	new DPolygon ptr	**dup**		Creates a copy of self
[const,iter]	DEdge	**each_edge**		Iterates over the edges that make up the polygon
[const,iter]	DEdge	**each_edge**	(unsigned int contour)	Iterates over the edges of one contour of the polygon

[const,iter]	DPoint	**each_point_hole**	(unsigned int n)	Iterates over the points that make up the nth hole
[const,iter]	DPoint	**each_point_hull**		Iterates over the points that make up the hull
[const]	variant[]	**extract_rad**		Extracts the corner radii from a rounded polygon
[const]	unsigned long	**hash**		Computes a hash value
[const]	unsigned int	**holes**		Returns the number of holes
	void	**hull=**	(DPoint[] p)	Sets the points of the hull of polygon
	void	**insert_hole**	(DPoint[] p, bool raw = false)	Inserts a hole with the given points
	void	**insert_hole**	(const DBox b)	Inserts a hole from the given box
[const]	bool	**inside?**	(DPoint p)	Tests, if the given point is inside the polygon
[const]	bool	**is_box?**		Returns true, if the polygon is a simple box.
[const]	bool	**is_empty?**		Returns a value indicating whether the polygon is empty
[const]	bool	**is_halfmanhattan?**		Returns a value indicating whether the polygon is half-manhattan
[const]	bool	**is_rectilinear?**		Returns a value indicating whether the polygon is rectilinear
	DPolygon	**move**	(const DVector p)	Moves the polygon.
	DPolygon	**move**	(double x, double y)	Moves the polygon.
[const]	DPolygon	**moved**	(const DVector p)	Returns the moved polygon (does not modify self)
[const]	DPolygon	**moved**	(double x, double y)	Returns the moved polygon (does not modify self)
[const]	unsigned long	**num_points**		Gets the total number of points (hull plus holes)
[const]	unsigned long	**num_points_hole**	(unsigned int n)	Gets the number of points of the given hole
[const]	unsigned long	**num_points_hull**		Gets the number of points of the hull
[const]	double	**perimeter**		Gets the perimeter of the polygon
[const]	DPoint	**point_hole**	(unsigned int n, unsigned long p)	Gets a specific point of a hole
[const]	DPoint	**point_hull**	(unsigned long p)	Gets a specific point of the hull

[const]	DPolygon	**round_corners**	(double rinner, double router, unsigned int n)	Rounds the corners of the polygon
	void	**size**	(double dx, double dy, unsigned int mode)	Sizes the polygon (biasing)
	void	**size**	(const Vector dv, unsigned int mode = 2)	Sizes the polygon (biasing)
	void	**size**	(double d, unsigned int mode = 2)	Sizes the polygon (biasing)
[const]	DPolygon	**sized**	(double dx, double dy, unsigned int mode)	Sizes the polygon (biasing) without modifying self
[const]	DPolygon	**sized**	(const Vector dv, unsigned int mode = 2)	Sizes the polygon (biasing) without modifying self
[const]	DPolygon	**sized**	(double d, unsigned int mode = 2)	Sizes the polygon (biasing) without modifying self
	void	**sort_holes**		Brings the holes in a specific order
[const]	DPolygon[]	**split**		Splits the polygon into two or more parts
[const]	Polygon	**to_itype**	(double dbu = 1)	Converts the polygon to an integer coordinate polygon
[const]	string	**to_s**		Returns a string representing the polygon
[const]	bool	**touches?**	(const DBox box)	Returns true, if the polygon touches the given box.
[const]	bool	**touches?**	(const DEdge edge)	Returns true, if the polygon touches the given edge.
[const]	bool	**touches?**	(const DPolygon polygon)	Returns true, if the polygon touches the other polygon.
[const]	bool	**touches?**	(const DSimplePolygon simple_polygon)	Returns true, if the polygon touches the other polygon.
	DPolygon ptr	**transform**	(const DCplxTrans t)	Transforms the polygon with a complex transformation (in-place)
	DPolygon ptr	**transform**	(const DTrans t)	Transforms the polygon (in-place)
[const]	Polygon	**transformed**	(const VCplxTrans t)	Transforms the polygon with the given complex transformation
[const]	DPolygon	**transformed**	(const DTrans t)	Transforms the polygon

[const]	DPolygon	**transformed**	(const DCplxTrans t)	Transforms the polygon with a complex transformation

Public static methods and constants

	new DPolygon ptr	**ellipse**	(const DBox box, int n)	Creates a simple polygon approximating an ellipse
	new DPolygon ptr	**from_s**	(string s)	Creates a polygon from a string

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**		Use of this method is deprecated. Use _create instead
	void	**destroy**		Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**		Use of this method is deprecated. Use _destroyed? instead
[static]	new DPolygon ptr	**from_ipoly**	(const Polygon polygon)	Use of this method is deprecated. Use new instead
[const]	bool	**is_const_object?**		Use of this method is deprecated. Use _is_const_object? instead
[const]	DPolygon	**transformed_cplx**	(const DCplxTrans t)	Use of this method is deprecated. Use transformed instead

Detailed description

!=

Signature: *[const]* bool **!=** (const DPolygon p)

Description: Returns a value indicating whether the polygons are not equal

p: The object to compare against

*****

Signature: *[const]* DPolygon ***** (double f)

Description: Scales the polygon by some factor

Returns the scaled object. All coordinates are multiplied with the given factor and if necessary rounded.

Python specific notes:
This method also implements '__rmul__'.

<

Signature: *[const]* bool **<** (const DPolygon p)

Description: Returns a value indicating whether self is less than p

p: The object to compare against

This operator is provided to establish some, not necessarily a certain sorting order

==

Signature: *[const]* bool **==** (const DPolygon p)

Description: Returns a value indicating whether the polygons are equal

p: The object to compare against

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

area

Signature: *[const]* double **area**

Description: Gets the area of the polygon

The area is correct only if the polygon is not self-overlapping and the polygon is oriented clockwise.Orientation is ensured automatically in most cases.

area2

Signature: *[const]* double **area2**

Description: Gets the double area of the polygon

This method is provided because the area for an integer-type polygon is a multiple of 1/2. Hence the double area can be expresses precisely as an integer for these types.

This method has been introduced in version 0.26.1

assign

Signature: void **assign** (const DPolygon other)

Description: Assigns another object to self

assign_hole

(1) Signature: void **assign_hole** (unsigned int n, DPoint[] p, bool raw = false)

Description: Sets the points of the given hole of the polygon

n:	The index of the hole to which the points should be assigned
p:	An array of points to assign to the polygon's hole
raw:	If true, the points won't be compressed (see assign_hull)

If the hole index is not valid, this method does nothing.

This method was introduced in version 0.18. The 'raw' argument was added in version 0.24.

(2) Signature: void **assign_hole** (unsigned int n, const DBox b)

Description: Sets the box as the given hole of the polygon

n:	The index of the hole to which the points should be assigned
b:	The box to assign to the polygon's hole

If the hole index is not valid, this method does nothing. This method was introduced in version 0.23.

assign_hull

Signature: void **assign_hull** (DPoint[] p, bool raw = false)

Description: Sets the points of the hull of polygon

p:	An array of points to assign to the polygon's hull
raw:	If true, the points won't be compressed

If the 'raw' argument is set to true, the points are taken as they are. Specifically no removal of redundant points or joining of coincident edges will take place. In effect, polygons consisting of a single point or two points can be constructed as well as polygons with duplicate points. Note that such polygons may cause problems in some applications.

Regardless of raw mode, the point list will be adjusted such that the first point is the lowest-leftmost one and the orientation is clockwise always.

The 'assign_hull' variant is provided in analogy to 'assign_hole'.

The 'raw' argument was added in version 0.24.

bbox

Signature: *[const]* DBox **bbox**

Description: Returns the bounding box of the polygon

The bounding box is the box enclosing all points of the polygon.

break

Signature: *[const]* DPolygon[] **break** (unsigned long max_vertex_count, double max_area_ratio)

Description: Splits the polygon into parts with a maximum vertex count and area ratio

The area ratio is the ratio between the bounding box area and the polygon area. Higher values mean more 'skinny' polygons.

This method will split the input polygon into pieces having a maximum of 'max_vertex_count' vertices and an area ratio less than 'max_area_ratio'. 'max_vertex_count' can be zero. In this case the limit is ignored. Also 'max_area_ratio' can be zero, in which case it is ignored as well.

The method of splitting is unspecified. The algorithm will apply 'split' recursively until the parts satisfy the limits.

This method has been introduced in version 0.29.

Python specific notes:
This attribute is available as 'break_' in Python.

compress

Signature: void **compress** (bool remove_reflected)

Description: Compresses the polygon.

remove_reflected: See description of the functionality.

This method removes redundant points from the polygon, such as points being on a line formed by two other points. If remove_reflected is true, points are also removed if the two adjacent edges form a spike.

This method was introduced in version 0.18.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new DPolygon ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

each_edge

(1) Signature: *[const,iter]* DEdge **each_edge**

Description: Iterates over the edges that make up the polygon

This iterator will deliver all edges, including those of the holes. Hole edges are oriented counterclockwise while hull edges are oriented clockwise.

(2) Signature: *[const,iter]* DEdge **each_edge** (unsigned int contour)

Description: Iterates over the edges of one contour of the polygon

contour: The contour number (0 for hull, 1 for first hole ...)

This iterator will deliver all edges of the contour specified by the contour parameter. The hull has contour number 0, the first hole has contour 1 etc. Hole edges are oriented counterclockwise while hull edges are oriented clockwise.

This method was introduced in version 0.24.

each_point_hole

Signature: *[const,iter]* DPoint **each_point_hole** (unsigned int n)

Description: Iterates over the points that make up the nth hole

The hole number must be less than the number of holes (see holes)

each_point_hull

Signature: *[const,iter]* DPoint **each_point_hull**

Description: Iterates over the points that make up the hull

ellipse

Signature: *[static]* new DPolygon ptr **ellipse** (const DBox box, int n)

Description: Creates a simple polygon approximating an ellipse

box: The bounding box of the ellipse

n: The number of points that will be used to approximate the ellipse

This method has been introduced in version 0.23.

extract_rad

Signature: *[const]* variant[] **extract_rad**

Description: Extracts the corner radii from a rounded polygon

Attempts to extract the radii of rounded corner polygon. This is essentially the inverse of the round_corners method. If this method succeeds, if will return an array of four elements:

- The polygon with the rounded corners replaced by edgy ones
- The radius of the inner corners
- The radius of the outer corners
- The number of points per full circle

This method is based on some assumptions and may fail. In this case, an empty array is returned.

If successful, the following code will more or less render the original polygon and parameters

```
p = ...   # some polygon
p.round_corners(ri, ro, n)
(p2, ri2, ro2, n2) = p.extract_rad
# -> p2 == p, ro2 == ro, ri2 == ri, n2 == n (within some limits)
```

This method was introduced in version 0.25.

from_ipoly

Signature: *[static]* new DPolygon ptr **from_ipoly** (const Polygon polygon)

Description: Creates a floating-point coordinate polygon from an integer coordinate polygon

Use of this method is deprecated. Use new instead

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_ipolygon'.

Python specific notes:
This method is the default initializer of the object.

from_s

Signature: *[static]* new DPolygon ptr **from_s** (string s)

Description: Creates a polygon from a string

Creates the object from a string representation (as returned by to_s)

This method has been added in version 0.23.

hash

Signature: *[const]* unsigned long **hash**

Description: Computes a hash value

Returns a hash value for the given polygon. This method enables polygons as hash keys.

This method has been introduced in version 0.25.

Python specific notes:
This method is also available as 'hash(object)'.

holes

Signature: *[const]* unsigned int **holes**

Description: Returns the number of holes

hull=

Signature: void **hull=** (DPoint[] p)

Description: Sets the points of the hull of polygon

p: An array of points to assign to the polygon's hull

The 'assign_hull' variant is provided in analogy to 'assign_hole'.

Python specific notes:
The object exposes a writable attribute 'hull'. This is the setter.

insert_hole

(1) Signature: void **insert_hole** (DPoint[] p, bool raw = false)

Description: Inserts a hole with the given points

p: An array of points to insert as a new hole

raw: If true, the points won't be compressed (see assign_hull)

The 'raw' argument was added in version 0.24.

(2) Signature: void **insert_hole** (const DBox b)

Description: Inserts a hole from the given box

b: The box to insert as a new hole

This method was introduced in version 0.23.

inside?

Signature: *[const]* bool **inside?** (DPoint p)

Description: Tests, if the given point is inside the polygon

If the given point is inside or on the edge of the polygon, true is returned. This tests works well only if the polygon is not self-overlapping and oriented clockwise.

is_box?

Signature: *[const]* bool **is_box?**

Description: Returns true, if the polygon is a simple box.

Returns: True if the polygon is a box.

A polygon is a box if it is identical to its bounding box.

This method was introduced in version 0.23.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_empty?

Signature: *[const]* bool **is_empty?**

Description: Returns a value indicating whether the polygon is empty

is_halfmanhattan?

Signature: *[const]* bool **is_halfmanhattan?**

Description: Returns a value indicating whether the polygon is half-manhattan

Half-manhattan polygons have edges which are multiples of 45 degree. These polygons can be clipped at a rectangle without potential grid snapping.

This predicate was introduced in version 0.27.

is_rectilinear?

Signature: *[const]* bool **is_rectilinear?**

Description: Returns a value indicating whether the polygon is rectilinear

move

(1) Signature: DPolygon **move** (const DVector p)

Description: Moves the polygon.

p: The distance to move the polygon.

Returns: The moved polygon (self).

Moves the polygon by the given offset and returns the moved polygon. The polygon is overwritten.

This method has been introduced in version 0.23.

(2) Signature: DPolygon **move** (double x, double y)

Description: Moves the polygon.

x: The x distance to move the polygon.

y: The y distance to move the polygon.

Returns: The moved polygon (self).

Moves the polygon by the given offset and returns the moved polygon. The polygon is overwritten.

moved

(1) Signature: *[const]* DPolygon **moved** (const DVector p)

Description: Returns the moved polygon (does not modify self)

p: The distance to move the polygon.

Returns: The moved polygon.

Moves the polygon by the given offset and returns the moved polygon. The polygon is not modified.

This method has been introduced in version 0.23.

(2) Signature: *[const]* DPolygon **moved** (double x, double y)

Description: Returns the moved polygon (does not modify self)

x: The x distance to move the polygon.

y: The y distance to move the polygon.

Returns: The moved polygon.

Moves the polygon by the given offset and returns the moved polygon. The polygon is not modified.

This method has been introduced in version 0.23.

new

(1) Signature: *[static]* new DPolygon ptr **new** (const Polygon polygon)

Description: Creates a floating-point coordinate polygon from an integer coordinate polygon

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_ipolygon'.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new DPolygon ptr **new**

Description: Creates an empty (invalid) polygon

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new DPolygon ptr **new** (const DSimplePolygon sp)

Description: Creates a polygon from a simple polygon

sp: The simple polygon that is converted into the polygon

This method was introduced in version 0.22.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new DPolygon ptr **new** (DPoint[] pts, bool raw = false)

Description: Creates a polygon from a point array for the hull

pts: The points forming the polygon hull

raw: If true, the point list won't be modified (see assign_hull)

The 'raw' argument was added in version 0.24.

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new DPolygon ptr **new** (const DBox box)

Description: Creates a polygon from a box

box: The box to convert to a polygon

Python specific notes:

This method is the default initializer of the object.

num_points

Signature: *[const]* unsigned long **num_points**

Description: Gets the total number of points (hull plus holes)

This method was introduced in version 0.18.

num_points_hole

Signature: *[const]* unsigned long **num_points_hole** (unsigned int n)

Description: Gets the number of points of the given hole

The argument gives the index of the hole of which the number of points are requested. The index must be less than the number of holes (see holes).

num_points_hull

Signature: *[const]* unsigned long **num_points_hull**

Description: Gets the number of points of the hull

perimeter

Signature: *[const]* double **perimeter**

Description: Gets the perimeter of the polygon

The perimeter is sum of the lengths of all edges making up the polygon.

This method has been introduce in version 0.23.

point_hole

Signature: *[const]* DPoint **point_hole** (unsigned int n, unsigned long p)

Description: Gets a specific point of a hole

n: The index of the hole to which the points should be assigned

p: The index of the point to get

If the index of the point or of the hole is not valid, a default value is returned. This method was introduced in version 0.18.

point_hull

Signature: *[const]* DPoint **point_hull** (unsigned long p)

Description: Gets a specific point of the hull

p: The index of the point to get

If the index of the point is not a valid index, a default value is returned. This method was introduced in version 0.18.

round_corners

Signature: *[const]* DPolygon **round_corners** (double rinner, double router, unsigned int n)

Description: Rounds the corners of the polygon

rinner: The circle radius of inner corners (in database units).

router: The circle radius of outer corners (in database units).

n: The number of points per full circle.

Returns: The new polygon.

Replaces the corners of the polygon with circle segments.

This method was introduced in version 0.20 for integer coordinates and in 0.25 for all coordinate types.

size

(1) Signature: void **size** (double dx, double dy, unsigned int mode)

Description: Sizes the polygon (biasing)

Shifts the contour outwards (dx,dy>0) or inwards (dx,dy<0). dx is the sizing in x-direction and dy is the sizing in y-direction. The sign of dx and dy should be identical. The sizing operation create invalid (self-overlapping, reverse oriented) contours.

The mode defines at which bending angle cutoff occurs (0:>0, 1:>45, 2:>90, 3:>135, 4:>approx. 168, other:>approx. 179)

In order to obtain a proper polygon in the general case, the sized polygon must be merged in 'greater than zero' wrap count mode. This is necessary since in the general case, sizing can be complicated operation which lets a single polygon fall apart into disjoint pieces for example. This can be achieved using the EdgeProcessor class for example:

```
poly = ... # a RBA::Polygon
poly.size(-50, 2)
ep = RBA::EdgeProcessor::new
# result is an array of RBA::Polygon objects
result = ep.simple_merge_p2p([ poly ], false, false, 1)
```

(2) Signature: void **size** (const Vector dv, unsigned int mode = 2)

Description: Sizes the polygon (biasing)

This method is equivalent to

```
size(dv.x, dv.y, mode)
```

See size for a detailed description.

This version has been introduced in version 0.28.

(3) Signature: void **size** (double d, unsigned int mode = 2)

Description: Sizes the polygon (biasing)

Shifts the contour outwards (d>0) or inwards (d<0). This method is equivalent to

```
size(d, d, mode)
```

See size for a detailed description.

This method has been introduced in version 0.23.

sized

(1) Signature: *[const]* DPolygon **sized** (double dx, double dy, unsigned int mode)

Description: Sizes the polygon (biasing) without modifying self

This method applies sizing to the polygon but does not modify self. Instead a sized copy is returned. See size for a description of the operation.

This method has been introduced in version 0.23.

(2) Signature: *[const]* DPolygon **sized** (const Vector dv, unsigned int mode = 2)

Description: Sizes the polygon (biasing) without modifying self

This method is equivalent to

```
sized(dv.x, dv.y, mode)
```

See size and sized for a detailed description.

This version has been introduced in version 0.28.

(3) Signature: *[const]* DPolygon **sized** (double d, unsigned int mode = 2)

Description: Sizes the polygon (biasing) without modifying self

Shifts the contour outwards (d>0) or inwards (d<0). This method is equivalent to

```
sized(d, d, mode)
```

See size and sized for a detailed description.

sort_holes

Signature: void **sort_holes**

Description: Brings the holes in a specific order

This function is normalize the hole order so the comparison of two polygons does not depend on the order the holes were inserted. Polygons generated by KLayout's alorithms have their holes sorted.

This method has been introduced in version 0.28.8.

split

Signature: *[const]* DPolygon[] **split**

Description: Splits the polygon into two or more parts

This method will break the polygon into parts. The exact breaking algorithm is unspecified, the result are smaller polygons of roughly equal number of points and 'less concave' nature. Usually the returned polygon set consists of two polygons, but there can be more. The merged region of the resulting polygons equals the original polygon with the exception of small snapping effects at new vertexes.

The intended use for this method is a iteratively split polygons until the satisfy some maximum number of points limit.

This method has been introduced in version 0.25.3.

to_itype

Signature: *[const]* Polygon **to_itype** (double dbu = 1)

Description: Converts the polygon to an integer coordinate polygon

The database unit can be specified to translate the floating-point coordinate polygon in micron units to an integer-coordinate polygon in database units. The polygons coordinates will be divided by the database unit.

This method has been introduced in version 0.25.

to_s

Signature: *[const]* string **to_s**

Description: Returns a string representing the polygon

Python specific notes:
This method is also available as 'str(object)'.

touches?

(1) Signature: *[const]* bool **touches?** (const DBox box)

Description: Returns true, if the polygon touches the given box.

The box and the polygon touch if they overlap or their contours share at least one point.

This method was introduced in version 0.25.1.

(2) Signature: *[const]* bool **touches?** (const DEdge edge)

Description: Returns true, if the polygon touches the given edge.

The edge and the polygon touch if they overlap or the edge shares at least one point with the polygon's contour.

This method was introduced in version 0.25.1.

(3) Signature: *[const]* bool **touches?** (const DPolygon polygon)

Description: Returns true, if the polygon touches the other polygon.

The polygons touch if they overlap or their contours share at least one point.

This method was introduced in version 0.25.1.

(4) Signature: *[const]* bool **touches?** (const DSimplePolygon simple_polygon)

Description: Returns true, if the polygon touches the other polygon.

The polygons touch if they overlap or their contours share at least one point.

This method was introduced in version 0.25.1.

transform

(1) Signature: DPolygon ptr **transform** (const DCplxTrans t)

Description: Transforms the polygon with a complex transformation (in-place)

t: The transformation to apply.

Transforms the polygon with the given complex transformation. Modifies self and returns self. An out-of-place version which does not modify self is transformed.

This method has been introduced in version 0.24.

(2) Signature: DPolygon ptr **transform** (const DTrans t)

Description: Transforms the polygon (in-place)

t: The transformation to apply.

Transforms the polygon with the given transformation. Modifies self and returns self. An out-of-place version which does not modify self is transformed.

This method has been introduced in version 0.24.

transformed

(1) Signature: *[const]* Polygon **transformed** (const VCplxTrans t)

Description: Transforms the polygon with the given complex transformation

t: The magnifying transformation to apply

Returns: The transformed polygon (in this case an integer coordinate polygon)

This method has been introduced in version 0.25.

(2) Signature: *[const]* DPolygon **transformed** (const DTrans t)

Description: Transforms the polygon

t: The transformation to apply.

Returns: The transformed polygon.

Transforms the polygon with the given transformation. Does not modify the polygon but returns the transformed polygon.

(3) Signature: *[const]* DPolygon **transformed** (const DCplxTrans t)

Description: Transforms the polygon with a complex transformation

t:	The transformation to apply.
Returns:	The transformed polygon.

Transforms the polygon with the given complex transformation. Does not modify the polygon but returns the transformed polygon.

With version 0.25, the original 'transformed_cplx' method is deprecated and 'transformed' takes both simple and complex transformations.

transformed_cplx

Signature: *[const]* DPolygon **transformed_cplx** (const DCplxTrans t)

Description: Transforms the polygon with a complex transformation

t:	The transformation to apply.
Returns:	The transformed polygon.

Use of this method is deprecated. Use transformed instead

Transforms the polygon with the given complex transformation. Does not modify the polygon but returns the transformed polygon.

With version 0.25, the original 'transformed_cplx' method is deprecated and 'transformed' takes both simple and complex transformations.

4.78. API reference - Class LayerMap

Notation used in Ruby API documentation

Module: db

Description: An object representing an arbitrary mapping of physical layers to logical layers

"Physical" layers are stream layers or other separated layers in a CAD file. "Logical" layers are the layers present in a Layout object. Logical layers are represented by an integer index while physical layers are given by a layer and datatype number or name. A logical layer is created automatically in the layout on reading if it does not exist yet.

The mapping describes an association of a set of physical layers to a set of logical ones, where multiple physical layers can be mapped to a single logical one, which effectively merges the layers.

For each logical layer, a target layer can be specified. A target layer is the layer/datatype/name combination as which the logical layer appears in the layout. By using a target layer different from the source layer renaming a layer can be achieved while loading a layout. Another use case for that feature is to assign layer names to GDS layer/datatype combinations which are numerical only.

LayerMap objects are used in two ways: as input for the reader (inside a LoadLayoutOptions class) and as output from the reader (i.e. Layout::read method). For layer map objects used as input, the layer indexes (logical layers) can be consecutive numbers. They do not need to correspond with real layer indexes from a layout object. When used as output, the layer map's logical layers correspond to the layer indexes inside the layout that the layer map was used upon.

This is a sample how to use the LayerMap object. It maps all datatypes of layers 1, 2 and 3 to datatype 0 and assigns the names 'ONE', 'TWO' and 'THREE' to these layout layers:

```
lm = RBA::LayerMap::new
lm.map("1/0-255 : ONE (1/0)")
lm.map("2/0-255 : TWO (2/0)")
lm.map("3/0-255 : THREE (3/0)")

# read the layout using the layer map
lo = RBA::LoadLayoutOptions::new
lo.layer_map.assign(lm)
ly = RBA::Layout::new
ly.read("input.gds", lo)
```

1:n mapping is supported: a physical layer can be mapped to multiple logical layers using 'mmap' instead of 'map'. When using this variant, mapping acts additive. The following example will map layer 1, datatypes 0 to 255 to logical layer 0, and layer 1, datatype 17 to logical layers 0 plus 1:

```
lm = RBA::LayerMap::new
lm.map("1/0-255", 0)   # (can be 'mmap' too)
lm.mmap("1/17", 1)
```

'unmapping' allows removing a mapping. This allows creating 'holes' in mapping ranges. The following example maps layer 1, datatypes 0 to 16 and 18 to 255 to logical layer 0:

```
lm = RBA::LayerMap::new
lm.map("1/0-255", 0)
lm.unmap("1/17")
```

The LayerMap class has been introduced in version 0.18. Target layer have been introduced in version 0.20. 1:n mapping and unmapping has been introduced in version 0.27.

Public constructors

new LayerMap ptr	**new**	Creates a new object of this class

Public methods

	void	_create		Ensures the C++ object is created
	void	_destroy		Explicitly destroys the object
[const]	bool	_destroyed?		Returns a value indicating whether the object was already destroyed
[const]	bool	_is_const_object?		Returns a value indicating whether the reference is a const reference
	void	_manage		Marks the object as managed by the script side.
	void	_unmanage		Marks the object as no longer owned by the script side.
	void	assign	(const LayerMap other)	Assigns another object to self
	void	clear		Clears the map
[const]	new LayerMap ptr	dup		Creates a copy of self
[const]	bool	is_mapped?	(const LayerInfo layer)	Check, if a given physical layer is mapped
[const]	unsigned int[]	logicals	(const LayerInfo layer)	Returns the logical layers for a given physical layer.n@param layer The physical layer specified with an LayerInfo object.
	void	map	(const LayerInfo phys_layer, unsigned int log_layer)	Maps a physical layer to a logical one
	void	map	(const LayerInfo phys_layer, unsigned int log_layer, const LayerInfo target_layer)	Maps a physical layer to a logical one with a target layer
	void	map	(const LayerInfo pl_start, const LayerInfo pl_stop, unsigned int log_layer)	Maps a physical layer interval to a logical one
	void	map	(const LayerInfo pl_start, const LayerInfo pl_stop, unsigned int log_layer, const LayerInfo layer_properties)	Maps a physical layer interval to a logical one with a target layer
	void	map	(string map_expr, int log_layer = -1)	Maps a physical layer given by a string to a logical one
[const]	LayerInfo	mapping	(unsigned int log_layer)	Returns the mapped physical (or target if one is specified) layer for a given logical layer
[const]	string	mapping_str	(unsigned int log_layer)	Returns the mapping string for a given logical layer

	void	**mmap**	(const LayerInfo phys_layer, unsigned int log_layer)	Maps a physical layer to a logical one and adds to existing mappings
	void	**mmap**	(const LayerInfo phys_layer, unsigned int log_layer, const LayerInfo target_layer)	Maps a physical layer to a logical one, adds to existing mappings and specifies a target layer
	void	**mmap**	(const LayerInfo pl_start, const LayerInfo pl_stop, unsigned int log_layer)	Maps a physical layer from the given interval to a logical one and adds to existing mappings
	void	**mmap**	(const LayerInfo pl_start, const LayerInfo pl_stop, unsigned int log_layer, const LayerInfo layer_properties)	Maps a physical layer from the given interval to a logical one, adds to existing mappings and specifies a target layer
	void	**mmap**	(string map_expr, int log_layer = -1)	Maps a physical layer given by an expression to a logical one and adds to existing mappings
[const]	string	**to_string**		Converts a layer mapping object to a string
	void	**unmap**	(const LayerInfo phys_layer)	Unmaps the given layer
	void	**unmap**	(const LayerInfo pl_start, const LayerInfo pl_stop)	Unmaps the layers from the given interval
	void	**unmap**	(string expr)	Unmaps the layers from the given expression

Public static methods and constants

LayerMap	**from_string**	(string s)	Creates a layer map from the given string

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**		Use of this method is deprecated. Use _create instead
	void	**destroy**		Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**		Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**		Use of this method is deprecated. Use _is_const_object? instead
[const]	int	**logical**	(const LayerInfo layer)	Use of this method is deprecated

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const LayerMap other)

Description: Assigns another object to self

clear

Signature: void **clear**

Description: Clears the map

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new LayerMap ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

from_string

Signature: *[static]* LayerMap **from_string** (string s)

Description: Creates a layer map from the given string

The format of the string is that used in layer mapping files: one mapping entry per line, comments are allowed using '#' or '//'. The format of each line is that used in the 'map(string, index)' method.

This method has been introduced in version 0.23.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_mapped?

Signature: *[const]* bool **is_mapped?** (const LayerInfo layer)

Description: Check, if a given physical layer is mapped

layer:	The physical layer specified with an LayerInfo object.
Returns:	True, if the layer is mapped.

logical

Signature: *[const]* int **logical** (const LayerInfo layer)

Description: Returns the logical layer (the layer index in the layout object) for a given physical layer.n@param layer The physical layer specified with an LayerInfo object.

Returns: The logical layer index or -1 if the layer is not mapped.

Use of this method is deprecated

This method is deprecated with version 0.27 as in this version, layers can be mapped to multiple targets which this method can't capture. Use logicals instead.

logicals

Signature: *[const]* unsigned int[] **logicals** (const LayerInfo layer)

Description: Returns the logical layers for a given physical layer.n@param layer The physical layer specified with an LayerInfo object.

Returns: This list of logical layers this physical layer as mapped to or empty if there is no mapping.

This method has been introduced in version 0.27.

map

(1) Signature: void **map** (const LayerInfo phys_layer, unsigned int log_layer)

Description: Maps a physical layer to a logical one

phys_layer: The physical layer (a LayerInfo object).

log_layer: The logical layer to which the physical layer is mapped.

In general, there may be more than one physical layer mapped to one logical layer. This method will add the given physical layer to the mapping for the logical layer.

(2) Signature: void **map** (const LayerInfo phys_layer, unsigned int log_layer, const LayerInfo target_layer)

Description: Maps a physical layer to a logical one with a target layer

phys_layer: The physical layer (a LayerInfo object).

log_layer: The logical layer to which the physical layer is mapped.

target_layer: The properties of the layer that will be created unless it already exists.

In general, there may be more than one physical layer mapped to one logical layer. This method will add the given physical layer to the mapping for the logical layer.

This method has been added in version 0.20.

(3) Signature: void **map** (const LayerInfo pl_start, const LayerInfo pl_stop, unsigned int log_layer)

Description: Maps a physical layer interval to a logical one

pl_start: The first physical layer (a LayerInfo object).

pl_stop: The last physical layer (a LayerInfo object).

log_layer: The logical layer to which the physical layers are mapped.

This method maps an interval of layers l1..l2 and datatypes d1..d2 to the mapping for the given logical layer. l1 and d1 are given by the pl_start argument, while l2 and d2 are given by the pl_stop argument.

(4) Signature: void **map** (const LayerInfo pl_start, const LayerInfo pl_stop, unsigned int log_layer, const LayerInfo layer_properties)

Description: Maps a physical layer interval to a logical one with a target layer

pl_start: The first physical layer (a LayerInfo object).

pl_stop: The last physical layer (a LayerInfo object).

log_layer: The logical layer to which the physical layers are mapped.

target_layer: The properties of the layer that will be created unless it already exists.

This method maps an interval of layers l1..l2 and datatypes d1..d2 to the mapping for the given logical layer. l1 and d1 are given by the pl_start argument, while l2 and d2 are given by the pl_stop argument. This method has been added in version 0.20.

(5) Signature: void **map** (string map_expr, int log_layer = -1)

Description: Maps a physical layer given by a string to a logical one

map_expr: The string describing the physical layer to map.

log_layer: The logical layer to which the physical layers are mapped.

The string expression is constructed using the syntax: "list[/list][;..]" for layer/datatype pairs. "list" is a sequence of numbers, separated by comma values or a range separated by a hyphen. Examples are: "1/2", "1-5/0", "1,2,5/0", "1/5;5/6".

layer/datatype wildcards can be specified with "*". When "*" is used for the upper limit, it is equivalent to "all layer above". When used alone, it is equivalent to "all layers". Examples: "1 / *", "* / 10-*"

Named layers are specified simply by specifying the name, if necessary in single or double quotes (if the name begins with a digit or contains non-word characters). layer/datatype and name descriptions can be mixed, i.e. "AA;1/5" (meaning: name "AA" or layer 1/datatype 5).

A target layer can be specified with the ":<target>" notation, where target is a valid string for a LayerProperties() object.

A target can include relative layer/datatype specifications and wildcards. For example, "1-10/0: *+1/0" will add 1 to the original layer number. "1-10/0-50: * / *" will use the original layers.

If the logical layer is negative or omitted, the method will select the next available one.

Target mapping has been added in version 0.20. The logical layer is optional since version 0.28.

mapping

Signature: *[const]* LayerInfo **mapping** (unsigned int log_layer)

Description: Returns the mapped physical (or target if one is specified) layer for a given logical layer

log_layer: The logical layer for which the mapping is requested.

Returns: A LayerInfo object which is the physical layer mapped to the logical layer.

In general, there may be more than one physical layer mapped to one logical layer. This method will return a single one of them. It will return the one with the lowest layer and datatype.

mapping_str

Signature: *[const]* string **mapping_str** (unsigned int log_layer)

Description: Returns the mapping string for a given logical layer

log_layer: The logical layer for which the mapping is requested.

Returns: A string describing the mapping.

The mapping string is compatible with the string that the "map" method accepts.

mmap

(1) Signature: void **mmap** (const LayerInfo phys_layer, unsigned int log_layer)

Description: Maps a physical layer to a logical one and adds to existing mappings

This method acts like the corresponding 'map' method, but adds the logical layer to the receivers of the given physical one. Hence this method implements 1:n mapping capabilities. For backward compatibility, 'map' still substitutes mapping.

Multi-mapping has been added in version 0.27.

(2) Signature: void **mmap** (const LayerInfo phys_layer, unsigned int log_layer, const LayerInfo target_layer)

Description: Maps a physical layer to a logical one, adds to existing mappings and specifies a target layer

This method acts like the corresponding 'map' method, but adds the logical layer to the receivers of the given physical one. Hence this method implements 1:n mapping capabilities. For backward compatibility, 'map' still substitutes mapping.

Multi-mapping has been added in version 0.27.

(3) Signature: void **mmap** (const LayerInfo pl_start, const LayerInfo pl_stop, unsigned int log_layer)

Description: Maps a physical layer from the given interval to a logical one and adds to existing mappings

This method acts like the corresponding 'map' method, but adds the logical layer to the receivers of the given physical one. Hence this method implements 1:n mapping capabilities. For backward compatibility, 'map' still substitutes mapping.

Multi-mapping has been added in version 0.27.

(4) Signature: void **mmap** (const LayerInfo pl_start, const LayerInfo pl_stop, unsigned int log_layer, const LayerInfo layer_properties)

Description: Maps a physical layer from the given interval to a logical one, adds to existing mappings and specifies a target layer

This method acts like the corresponding 'map' method, but adds the logical layer to the receivers of the given physical one. Hence this method implements 1:n mapping capabilities. For backward compatibility, 'map' still substitutes mapping.

Multi-mapping has been added in version 0.27.

(5) Signature: void **mmap** (string map_expr, int log_layer = -1)

Description: Maps a physical layer given by an expression to a logical one and adds to existing mappings

This method acts like the corresponding 'map' method, but adds the logical layer to the receivers of the given physical one. Hence this method implements 1:n mapping capabilities. For backward compatibility, 'map' still substitutes mapping.

If the logical layer is negative or omitted, the method will select the next available one.

Multi-mapping has been added in version 0.27. The logical layer is optional since version 0.28.

new

Signature: *[static]* new LayerMap ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

to_string

Signature: *[const]* string **to_string**

Description: Converts a layer mapping object to a string

This method is the inverse of the from_string method.

This method has been introduced in version 0.23.

unmap

(1) Signature: void **unmap** (const LayerInfo phys_layer)

Description: Unmaps the given layer

Unmapping will remove the specific layer from the mapping. This method allows generating 'mapping holes' by first mapping a range and then unmapping parts of it.

This method has been introduced in version 0.27.

(2) Signature: void **unmap** (const LayerInfo pl_start, const LayerInfo pl_stop)

Description: Unmaps the layers from the given interval

This method has been introduced in version 0.27.

(3) Signature: void **unmap** (string expr)

Description: Unmaps the layers from the given expression

This method has been introduced in version 0.27.

4.79. API reference - Class LoadLayoutOptions

Notation used in Ruby API documentation

Module: db

Description: Layout reader options

Sub-classes: CellConflictResolution

This object describes various layer reader options used for loading layouts.

This class has been introduced in version 0.18.

Public constructors

new LoadLayoutOptions ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const LoadLayoutOptior other)	Assigns another object to self
[const]	LoadLayoutOptions::CellConflictResolution	**cell_conflict_resolution**		Gets the cell conflict resolution mode
	void	**cell_conflict_resolution=**	(LoadLayoutOptio mode)	Sets the cell conflict resolution mode
	void	**cif_create_other_layers=**	(bool create)	Specifies whether other layers shall be created
[const]	bool	**cif_create_other_layers?**		Gets a value indicating whether other layers shall be created
[const]	double	**cif_dbu**		Specifies the database unit which the reader uses and produces
	void	**cif_dbu=**	(double dbu)	Specifies the database unit which the reader uses and produces
	void	**cif_keep_layer_names=**	(bool keep)	Gets a value indicating whether layer names are kept

[const]	bool	**cif_keep_layer_names?**		Gets a value indicating whether layer names are kept
	LayerMap	**cif_layer_map**		Gets the layer map
	void	**cif_layer_map=**	(const LayerMap map)	Sets the layer map
	void	**cif_select_all_layers**		Selects all layers and disables the layer map
	void	**cif_set_layer_map**	(const LayerMap map, bool create_other_laye	Sets the layer map
[const]	unsigned int	**cif_wire_mode**		Specifies how to read 'W' objects
	void	**cif_wire_mode=**	(unsigned int mode)	How to read 'W' objects
	void	**create_other_layers=**	(bool create)	Specifies whether other layers shall be created
[const]	bool	**create_other_layers?**		Gets a value indicating whether other layers shall be created
[const]	new LoadLayoutOptions ptr	**dup**		Creates a copy of self
[const]	double	**dxf_circle_accuracy**		Gets the accuracy of the circle approximation
	void	**dxf_circle_accuracy=**	(double accuracy)	Specifies the accuracy of the circle approximation
[const]	int	**dxf_circle_points**		Gets the number of points used per full circle for arc interpolation
	void	**dxf_circle_points=**	(int points)	Specifies the number of points used per full circle for arc interpolation
[const]	double	**dxf_contour_accuracy**		Gets the accuracy for contour closing
	void	**dxf_contour_accuracy=**	(double accuracy)	Specifies the accuracy for contour closing
	void	**dxf_create_other_layers=**	(bool create)	Specifies whether other layers shall be created
[const]	bool	**dxf_create_other_layers?**		Gets a value indicating whether other layers shall be created
[const]	double	**dxf_dbu**		Specifies the database unit which the reader uses and produces
	void	**dxf_dbu=**	(double dbu)	Specifies the database unit which the reader uses and produces

	void	**dxf_keep_layer_names=**	(bool keep)	Gets a value indicating whether layer names are kept
[const]	bool	**dxf_keep_layer_names?**		Gets a value indicating whether layer names are kept
	void	**dxf_keep_other_cells=**	(bool value)	If this option is set to true, all cells are kept, not only the top cell and its children
[const]	bool	**dxf_keep_other_cells?**		If this option is true, all cells are kept, not only the top cell and its children
	LayerMap	**dxf_layer_map**		Gets the layer map
	void	**dxf_layer_map=**	(const LayerMap map)	Sets the layer map
[const]	int	**dxf_polyline_mode**		Specifies whether closed POLYLINE and LWPOLYLINE entities with width 0 are converted to polygons.
	void	**dxf_polyline_mode=**	(int mode)	Specifies how to treat POLYLINE/ LWPOLYLINE entities.
	void	**dxf_render_texts_as_polyg**	(bool value)	If this option is set to true, text objects are rendered as polygons
[const]	bool	**dxf_render_texts_as_polygons?**		If this option is true, text objects are rendered as polygons
	void	**dxf_select_all_layers**		Selects all layers and disables the layer map
	void	**dxf_set_layer_map**	(const LayerMap map, bool create_other_layers)	Sets the layer map
[const]	double	**dxf_text_scaling**		Gets the text scaling factor (see dxf_text_scaling=)
	void	**dxf_text_scaling=**	(double unit)	Specifies the text scaling in percent of the default scaling
[const]	double	**dxf_unit**		Specifies the unit in which the DXF file is drawn
	void	**dxf_unit=**	(double unit)	Specifies the unit in which the DXF file is drawn.
	void	**gds2_allow_big_records=**	(bool flag)	Allows big records with more than 32767 bytes
[const]	bool	**gds2_allow_big_records?**		Gets a value specifying whether to allow big records with a length of 32768 to 65535 bytes.

	void	gds2_allow_multi_xy_recor	(bool flag)	Allows the use of multiple XY records in BOUNDARY elements for unlimited large polygons
[const]	bool	gds2_allow_multi_xy_records?		Gets a value specifying whether to allow big polygons with multiple XY records.
[const]	unsigned int	gds2_box_mode		Gets a value specifying how to treat BOX records
	void	gds2_box_mode=	(unsigned int mode)	Sets a value specifying how to treat BOX records
	LayerMap	layer_map		Gets the layer map
	void	layer_map=	(const LayerMap map)	Sets the layer map, but does not affect the "create_other_layers" flag.
	LEFDEFReaderCon	lefdef_config		Gets a copy of the LEF/DEF reader configuration
	void	lefdef_config=	(const LEFDEFReaderConfiguration config)	Sets the LEF/DEF reader configuration
	void	mag_create_other_layers=	(bool create)	Specifies whether other layers shall be created
[const]	bool	mag_create_other_layers?		Gets a value indicating whether other layers shall be created
[const]	double	mag_dbu		Specifies the database unit which the reader uses and produces
	void	mag_dbu=	(double dbu)	Specifies the database unit which the reader uses and produces
	void	mag_keep_layer_names=	(bool keep)	Gets a value indicating whether layer names are kept
[const]	bool	mag_keep_layer_names?		Gets a value indicating whether layer names are kept
[const]	double	mag_lambda		Gets the lambda value
	void	mag_lambda=	(double lambda)	Specifies the lambda value to used for reading
	LayerMap	mag_layer_map		Gets the layer map
	void	mag_layer_map=	(const LayerMap map)	Sets the layer map
[const]	string[]	mag_library_paths		Gets the locations where to look up libraries (in this order)

	void	**mag_library_paths=**	(string[] lib_paths)	Specifies the locations where to look up libraries (in this order)
	void	**mag_merge=**	(bool merge)	Sets a value indicating whether boxes are merged into polygons
[const]	bool	**mag_merge?**		Gets a value indicating whether boxes are merged into polygons
	void	**mag_select_all_layers**		Selects all layers and disables the layer map
	void	**mag_set_layer_map**	(const LayerMap map, bool create_other_layers)	Sets the layer map
	void	**properties_enabled=**	(bool enabled)	Specifies whether properties should be read
[const]	bool	**properties_enabled?**		Gets a value indicating whether properties shall be read
	void	**select_all_layers**		Selects all layers and disables the layer map
	void	**set_layer_map**	(const LayerMap map, bool create_other_layers)	Sets the layer map
	void	**text_enabled=**	(bool enabled)	Specifies whether text objects shall be read
[const]	bool	**text_enabled?**		Gets a value indicating whether text objects shall be read
[const]	int	**warn_level**		Sets the warning level.
	void	**warn_level=**	(int level)	Sets the warning level.

Public static methods and constants

[static,const]	LoadLayoutOptions::CellConflictRe	**AddToCell**		Add content to existing cell
[static,const]	LoadLayoutOptions::CellConflictResolution	**OverwriteCell**		The old cell is overwritten entirely (including child cells which are not used otherwise)
[static,const]	LoadLayoutOptions::CellConflictRe	**RenameCell**		The new cell will be renamed to become unique
[static,const]	LoadLayoutOptions::CellConflictResolution	**SkipNewCell**		The new cell is skipped entirely (including child cells which are not used otherwise)
	LoadLayoutOptions	**from_technology**	(string technology	Gets the reader options of a given technology

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**dxf_keep_other_cells**	Use of this method is deprecated. Use dxf_keep_other_cells? instead
[const]	bool	**dxf_render_texts_as_polygo**	Use of this method is deprecated. Use dxf_render_texts_as_polygons? instead
[const]	bool	**gds2_allow_big_records**	Use of this method is deprecated. Use gds2_allow_big_records? instead
[const]	bool	**gds2_allow_multi_xy_record**	Use of this method is deprecated. Use gds2_allow_multi_xy_records? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead
[const]	bool	**is_properties_enabled?**	Use of this method is deprecated. Use properties_enabled? instead
[const]	bool	**is_text_enabled?**	Use of this method is deprecated. Use text_enabled? instead

Detailed description

AddToCell

Signature: *[static,const]* LoadLayoutOptions::CellConflictResolution **AddToCell**

Description: Add content to existing cell

This is the mode use in before version 0.27. Content of new cells is simply added to existing cells with the same name.

Python specific notes:
The object exposes a readable attribute 'AddToCell'. This is the getter.

OverwriteCell

Signature: *[static,const]* LoadLayoutOptions::CellConflictResolution **OverwriteCell**

Description: The old cell is overwritten entirely (including child cells which are not used otherwise)

Python specific notes:
The object exposes a readable attribute 'OverwriteCell'. This is the getter.

RenameCell

Signature: *[static,const]* LoadLayoutOptions::CellConflictResolution **RenameCell**

Description: The new cell will be renamed to become unique

Python specific notes:
The object exposes a readable attribute 'RenameCell'. This is the getter.

SkipNewCell

Signature: *[static,const]* LoadLayoutOptions::CellConflictResolution **SkipNewCell**

Description: The new cell is skipped entirely (including child cells which are not used otherwise)

Python specific notes:
The object exposes a readable attribute 'SkipNewCell'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const LoadLayoutOptions other)

Description: Assigns another object to self

cell_conflict_resolution

Signature: *[const]* LoadLayoutOptions::CellConflictResolution **cell_conflict_resolution**

Description: Gets the cell conflict resolution mode

Multiple layout files can be collected into a single Layout object by reading file after file into the Layout object. Cells with same names are considered a conflict. This mode indicates how such conflicts are resolved. See LoadLayoutOptions::CellConflictResolution for the values allowed. The default mode is LoadLayoutOptions::CellConflictResolution#AddToCell.

This option has been introduced in version 0.27.

Python specific notes:
The object exposes a readable attribute 'cell_conflict_resolution'. This is the getter.

cell_conflict_resolution=

Signature: void **cell_conflict_resolution=** (LoadLayoutOptions::CellConflictResolution mode)

Description: Sets the cell conflict resolution mode

See cell_conflict_resolution for details about this option.

This option has been introduced in version 0.27.

Python specific notes:
The object exposes a writable attribute 'cell_conflict_resolution'. This is the setter.

cif_create_other_layers=

Signature: void **cif_create_other_layers=** (bool create)

Description: Specifies whether other layers shall be created

create: True, if other layers will be created.

See cif_create_other_layers? for a description of this attribute.

This method has been added in version 0.25 and replaces the respective global option in LoadLayoutOptions in a format-specific fashion.

Python specific notes:
The object exposes a writable attribute 'cif_create_other_layers'. This is the setter.

cif_create_other_layers?

Signature: *[const]* bool **cif_create_other_layers?**

Description: Gets a value indicating whether other layers shall be created

Returns: True, if other layers will be created.

This attribute acts together with a layer map (see cif_layer_map=). Layers not listed in this map are created as well when cif_create_other_layers? is true. Otherwise they are ignored.

This method has been added in version 0.25 and replaces the respective global option in LoadLayoutOptions in a format-specific fashion.

Python specific notes:
The object exposes a readable attribute 'cif_create_other_layers'. This is the getter.

cif_dbu

Signature: *[const]* double **cif_dbu**

Description: Specifies the database unit which the reader uses and produces

See cif_dbu= method for a description of this property. This property has been added in version 0.21.

Python specific notes:
The object exposes a readable attribute 'cif_dbu'. This is the getter.

cif_dbu=

Signature: void **cif_dbu=** (double dbu)

Description: Specifies the database unit which the reader uses and produces

This property has been added in version 0.21.

Python specific notes:
The object exposes a writable attribute 'cif_dbu'. This is the setter.

cif_keep_layer_names=

Signature: void **cif_keep_layer_names=** (bool keep)

Description: Gets a value indicating whether layer names are kept

keep: True, if layer names are to be kept.

See cif_keep_layer_names? for a description of this property.

This method has been added in version 0.25.3.

Python specific notes:
The object exposes a writable attribute 'cif_keep_layer_names'. This is the setter.

cif_keep_layer_names?

Signature: *[const]* bool **cif_keep_layer_names?**

Description: Gets a value indicating whether layer names are kept

Returns: True, if layer names are kept.

When set to true, no attempt is made to translate layer names to GDS layer/datatype numbers. If set to false (the default), a layer named "L2D15" will be translated to GDS layer 2, datatype 15.

This method has been added in version 0.25.3.

Python specific notes:
The object exposes a readable attribute 'cif_keep_layer_names'. This is the getter.

cif_layer_map

Signature: LayerMap **cif_layer_map**

Description: Gets the layer map

Returns: A reference to the layer map

This method has been added in version 0.25 and replaces the respective global option in LoadLayoutOptions in a format-specific fashion.

Python note: this method has been turned into a property in version 0.26.

Python specific notes:
The object exposes a readable attribute 'cif_layer_map'. This is the getter.

cif_layer_map=

Signature: void **cif_layer_map=** (const LayerMap map)

Description: Sets the layer map

map: The layer map to set.

This sets a layer mapping for the reader. Unlike cif_set_layer_map, the 'create_other_layers' flag is not changed.

This convenience method has been added in version 0.26.

Python specific notes:
The object exposes a writable attribute 'cif_layer_map'. This is the setter.

cif_select_all_layers

Signature: void **cif_select_all_layers**

Description: Selects all layers and disables the layer map

This disables any layer map and enables reading of all layers. New layers will be created when required.

This method has been added in version 0.25 and replaces the respective global option in LoadLayoutOptions in a format-specific fashion.

cif_set_layer_map

Signature: void **cif_set_layer_map** (const LayerMap map, bool create_other_layers)

Description: Sets the layer map

map:	The layer map to set.
create_other_layers:	The flag indicating whether other layers will be created as well. Set to false to read only the layers in the layer map.

This sets a layer mapping for the reader. The layer map allows selection and translation of the original layers, for example to assign layer/datatype numbers to the named layers.

This method has been added in version 0.25 and replaces the respective global option in LoadLayoutOptions in a format-specific fashion.

cif_wire_mode

Signature: *[const]* unsigned int **cif_wire_mode**

Description: Specifies how to read 'W' objects

See cif_wire_mode= method for a description of this mode. This property has been added in version 0.21 and was renamed to cif_wire_mode in 0.25.

Python specific notes:
The object exposes a readable attribute 'cif_wire_mode'. This is the getter.

cif_wire_mode=

Signature: void **cif_wire_mode=** (unsigned int mode)

Description: How to read 'W' objects

This property specifies how to read 'W' (wire) objects. Allowed values are 0 (as square ended paths), 1 (as flush ended paths), 2 (as round paths)

This property has been added in version 0.21.

Python specific notes:
The object exposes a writable attribute 'cif_wire_mode'. This is the setter.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

create_other_layers=

Signature: void **create_other_layers=** (bool create)

Description: Specifies whether other layers shall be created

create:	True, if other layers should be created.

See create_other_layers? for a description of this attribute.

Starting with version 0.25 this option only applies to GDS2 and OASIS format. Other formats provide their own configuration.

Python specific notes:
The object exposes a writable attribute 'create_other_layers'. This is the setter.

create_other_layers?

Signature: *[const]* bool **create_other_layers?**

Description: Gets a value indicating whether other layers shall be created

Returns:	True, if other layers should be created.

This attribute acts together with a layer map (see layer_map=). Layers not listed in this map are created as well when create_other_layers? is true. Otherwise they are ignored.

Starting with version 0.25 this option only applies to GDS2 and OASIS format. Other formats provide their own configuration.

Python specific notes:
The object exposes a readable attribute 'create_other_layers'. This is the getter.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new LoadLayoutOptions ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

dxf_circle_accuracy

Signature: *[const]* double **dxf_circle_accuracy**

Description: Gets the accuracy of the circle approximation

This property has been added in version 0.24.9.

Python specific notes:
The object exposes a readable attribute 'dxf_circle_accuracy'. This is the getter.

dxf_circle_accuracy=

Signature: void **dxf_circle_accuracy=** (double accuracy)

Description: Specifies the accuracy of the circle approximation

In addition to the number of points per circle, the circle accuracy can be specified. If set to a value larger than the database unit, the number of points per circle will be chosen such that the deviation from the ideal circle becomes less than this value.

The actual number of points will not become bigger than the points specified through dxf_circle_points=. The accuracy value is given in the DXF file units (see dxf_unit) which is usually micrometers.

dxf_circle_points and dxf_circle_accuracy also apply to other "round" structures such as arcs, ellipses and splines in the same sense than for circles.

This property has been added in version 0.24.9.

Python specific notes:
The object exposes a writable attribute 'dxf_circle_accuracy'. This is the setter.

dxf_circle_points

Signature: *[const]* int **dxf_circle_points**

Description: Gets the number of points used per full circle for arc interpolation

This property has been added in version 0.21.6.

Python specific notes:

The object exposes a readable attribute 'dxf_circle_points'. This is the getter.

dxf_circle_points=

Signature: void **dxf_circle_points=** (int points)

Description: Specifies the number of points used per full circle for arc interpolation

See also dxf_circle_accuracy for how to specify the number of points based on an approximation accuracy.

dxf_circle_points and dxf_circle_accuracy also apply to other "round" structures such as arcs, ellipses and splines in the same sense than for circles.

This property has been added in version 0.21.6.

Python specific notes:
The object exposes a writable attribute 'dxf_circle_points'. This is the setter.

dxf_contour_accuracy

Signature: *[const]* double **dxf_contour_accuracy**

Description: Gets the accuracy for contour closing

This property has been added in version 0.25.3.

Python specific notes:
The object exposes a readable attribute 'dxf_contour_accuracy'. This is the getter.

dxf_contour_accuracy=

Signature: void **dxf_contour_accuracy=** (double accuracy)

Description: Specifies the accuracy for contour closing

When polylines need to be connected or closed, this value is used to indicate the accuracy. This is the value (in DXF units) by which points may be separated and still be considered connected. The default is 0.0 which implies exact (within one DBU) closing.

This value is effective in polyline mode 3 and 4.

This property has been added in version 0.25.3.

Python specific notes:
The object exposes a writable attribute 'dxf_contour_accuracy'. This is the setter.

dxf_create_other_layers=

Signature: void **dxf_create_other_layers=** (bool create)

Description: Specifies whether other layers shall be created

create: True, if other layers will be created.

See dxf_create_other_layers? for a description of this attribute.

This method has been added in version 0.25 and replaces the respective global option in LoadLayoutOptions in a format-specific fashion.

Python specific notes:
The object exposes a writable attribute 'dxf_create_other_layers'. This is the setter.

dxf_create_other_layers?

Signature: *[const]* bool **dxf_create_other_layers?**

Description: Gets a value indicating whether other layers shall be created

Returns: True, if other layers will be created.

This attribute acts together with a layer map (see dxf_layer_map=). Layers not listed in this map are created as well when dxf_create_other_layers? is true. Otherwise they are ignored.

This method has been added in version 0.25 and replaces the respective global option in LoadLayoutOptions in a format-specific fashion.

Python specific notes:

The object exposes a readable attribute 'dxf_create_other_layers'. This is the getter.

dxf_dbu

Signature: *[const]* double **dxf_dbu**

Description: Specifies the database unit which the reader uses and produces

This property has been added in version 0.21.

Python specific notes:
The object exposes a readable attribute 'dxf_dbu'. This is the getter.

dxf_dbu=

Signature: void **dxf_dbu=** (double dbu)

Description: Specifies the database unit which the reader uses and produces

This property has been added in version 0.21.

Python specific notes:
The object exposes a writable attribute 'dxf_dbu'. This is the setter.

dxf_keep_layer_names=

Signature: void **dxf_keep_layer_names=** (bool keep)

Description: Gets a value indicating whether layer names are kept

keep: True, if layer names are to be kept.

See cif_keep_layer_names? for a description of this property.

This method has been added in version 0.25.3.

Python specific notes:
The object exposes a writable attribute 'dxf_keep_layer_names'. This is the setter.

dxf_keep_layer_names?

Signature: *[const]* bool **dxf_keep_layer_names?**

Description: Gets a value indicating whether layer names are kept

Returns: True, if layer names are kept.

When set to true, no attempt is made to translate layer names to GDS layer/datatype numbers. If set to false (the default), a layer named "L2D15" will be translated to GDS layer 2, datatype 15.

This method has been added in version 0.25.3.

Python specific notes:
The object exposes a readable attribute 'dxf_keep_layer_names'. This is the getter.

dxf_keep_other_cells

Signature: *[const]* bool **dxf_keep_other_cells**

Description: If this option is true, all cells are kept, not only the top cell and its children

Use of this method is deprecated. Use dxf_keep_other_cells? instead

This property has been added in version 0.21.15.

Python specific notes:
The object exposes a readable attribute 'dxf_keep_other_cells'. This is the getter.
This method is available as 'dxf_keep_other_cells_' in Python to distiguish it from the property with the same name.

dxf_keep_other_cells=

Signature: void **dxf_keep_other_cells=** (bool value)

Description: If this option is set to true, all cells are kept, not only the top cell and its children

This property has been added in version 0.21.15.

Python specific notes:

The object exposes a writable attribute 'dxf_keep_other_cells'. This is the setter.

dxf_keep_other_cells?

Signature: *[const]* bool **dxf_keep_other_cells?**

Description: If this option is true, all cells are kept, not only the top cell and its children

This property has been added in version 0.21.15.

Python specific notes:
The object exposes a readable attribute 'dxf_keep_other_cells'. This is the getter.
This method is available as 'dxf_keep_other_cells_' in Python to distiguish it from the property with the same name.

dxf_layer_map

Signature: LayerMap **dxf_layer_map**

Description: Gets the layer map

Returns: A reference to the layer map

This method has been added in version 0.25 and replaces the respective global option in LoadLayoutOptions in a format-specific fashion. Python note: this method has been turned into a property in version 0.26.

Python specific notes:
The object exposes a readable attribute 'dxf_layer_map'. This is the getter.

dxf_layer_map=

Signature: void **dxf_layer_map=** (const LayerMap map)

Description: Sets the layer map

map: The layer map to set.

This sets a layer mapping for the reader. Unlike dxf_set_layer_map, the 'create_other_layers' flag is not changed.

This convenience method has been added in version 0.26.

Python specific notes:
The object exposes a writable attribute 'dxf_layer_map'. This is the setter.

dxf_polyline_mode

Signature: *[const]* int **dxf_polyline_mode**

Description: Specifies whether closed POLYLINE and LWPOLYLINE entities with width 0 are converted to polygons.

See dxf_polyline_mode= for a description of this property.

This property has been added in version 0.21.3.

Python specific notes:
The object exposes a readable attribute 'dxf_polyline_mode'. This is the getter.

dxf_polyline_mode=

Signature: void **dxf_polyline_mode=** (int mode)

Description: Specifies how to treat POLYLINE/LWPOLYLINE entities.

The mode is 0 (automatic), 1 (keep lines), 2 (create polygons from closed polylines with width = 0), 3 (merge all lines with width = 0 into polygons), 4 (as 3 plus auto-close open contours).

This property has been added in version 0.21.3.

Python specific notes:
The object exposes a writable attribute 'dxf_polyline_mode'. This is the setter.

dxf_render_texts_as_polygor

Signature: *[const]* bool **dxf_render_texts_as_polygons**

Description: If this option is true, text objects are rendered as polygons

Use of this method is deprecated. Use dxf_render_texts_as_polygons? instead

This property has been added in version 0.21.15.

Python specific notes:
The object exposes a readable attribute 'dxf_render_texts_as_polygons'. This is the getter.
This method is available as 'dxf_render_texts_as_polygons_' in Python to distiguish it from the property with the same name.

dxf_render_texts_as_polygons=

Signature: void **dxf_render_texts_as_polygons=** (bool value)

Description: If this option is set to true, text objects are rendered as polygons

This property has been added in version 0.21.15.

Python specific notes:
The object exposes a writable attribute 'dxf_render_texts_as_polygons'. This is the setter.

dxf_render_texts_as_polygon

Signature: *[const]* bool **dxf_render_texts_as_polygons?**

Description: If this option is true, text objects are rendered as polygons

This property has been added in version 0.21.15.

Python specific notes:
The object exposes a readable attribute 'dxf_render_texts_as_polygons'. This is the getter.
This method is available as 'dxf_render_texts_as_polygons_' in Python to distiguish it from the property with the same name.

dxf_select_all_layers

Signature: void **dxf_select_all_layers**

Description: Selects all layers and disables the layer map

This disables any layer map and enables reading of all layers. New layers will be created when required.

This method has been added in version 0.25 and replaces the respective global option in LoadLayoutOptions in a format-specific fashion.

dxf_set_layer_map

Signature: void **dxf_set_layer_map** (const LayerMap map, bool create_other_layers)

Description: Sets the layer map

map:	The layer map to set.
create_other_layers:	The flag indicating whether other layers will be created as well. Set to false to read only the layers in the layer map.

This sets a layer mapping for the reader. The layer map allows selection and translation of the original layers, for example to assign layer/datatype numbers to the named layers.

This method has been added in version 0.25 and replaces the respective global option in LoadLayoutOptions in a format-specific fashion.

dxf_text_scaling

Signature: *[const]* double **dxf_text_scaling**

Description: Gets the text scaling factor (see dxf_text_scaling=)

This property has been added in version 0.21.20.

Python specific notes:
The object exposes a readable attribute 'dxf_text_scaling'. This is the getter.

dxf_text_scaling=

Signature: void **dxf_text_scaling=** (double unit)

Description: Specifies the text scaling in percent of the default scaling

The default value 100, meaning that the letter pitch is roughly 92 percent of the specified text height. Decrease this value to get smaller fonts and increase it to get larger fonts.

This property has been added in version 0.21.20.

Python specific notes:
The object exposes a writable attribute 'dxf_text_scaling'. This is the setter.

dxf_unit

Signature: *[const]* double **dxf_unit**

Description: Specifies the unit in which the DXF file is drawn

This property has been added in version 0.21.3.

Python specific notes:
The object exposes a readable attribute 'dxf_unit'. This is the getter.

dxf_unit=

Signature: void **dxf_unit=** (double unit)

Description: Specifies the unit in which the DXF file is drawn.

This property has been added in version 0.21.3.

Python specific notes:
The object exposes a writable attribute 'dxf_unit'. This is the setter.

from_technology

Signature: *[static]* LoadLayoutOptions **from_technology** (string technology)

Description: Gets the reader options of a given technology

technology: The name of the technology to apply

Returns the reader options of a specific technology. If the technology name is not valid or an empty string, the reader options of the default technology are returned.

This method has been introduced in version 0.25

gds2_allow_big_records

Signature: *[const]* bool **gds2_allow_big_records**

Description: Gets a value specifying whether to allow big records with a length of 32768 to 65535 bytes.

Use of this method is deprecated. Use gds2_allow_big_records? instead

See gds2_allow_big_records= method for a description of this property. This property has been added in version 0.18.

Python specific notes:
The object exposes a readable attribute 'gds2_allow_big_records'. This is the getter.
This method is available as 'gds2_allow_big_records_' in Python to distiguish it from the property with the same name.

gds2_allow_big_records=

Signature: void **gds2_allow_big_records=** (bool flag)

Description: Allows big records with more than 32767 bytes

Setting this property to true allows larger records by treating the record length as unsigned short, which for example allows larger polygons (~8000 points rather than ~4000 points) without using multiple XY records. For strict compatibility with the standard, this property should be set to false. The default is true.

This property has been added in version 0.18.

Python specific notes:
The object exposes a writable attribute 'gds2_allow_big_records'. This is the setter.

gds2_allow_big_records?

Signature: *[const]* bool **gds2_allow_big_records?**

Description: Gets a value specifying whether to allow big records with a length of 32768 to 65535 bytes.

See gds2_allow_big_records= method for a description of this property. This property has been added in version 0.18.

Python specific notes:
The object exposes a readable attribute 'gds2_allow_big_records'. This is the getter.
This method is available as 'gds2_allow_big_records_' in Python to distiguish it from the property with the same name.

gds2_allow_multi_xy_records

Signature: *[const]* bool **gds2_allow_multi_xy_records**

Description: Gets a value specifying whether to allow big polygons with multiple XY records.

Use of this method is deprecated. Use gds2_allow_multi_xy_records? instead

See gds2_allow_multi_xy_records= method for a description of this property. This property has been added in version 0.18.

Python specific notes:
The object exposes a readable attribute 'gds2_allow_multi_xy_records'. This is the getter.
This method is available as 'gds2_allow_multi_xy_records_' in Python to distiguish it from the property with the same name.

gds2_allow_multi_xy_record

Signature: void **gds2_allow_multi_xy_records=** (bool flag)

Description: Allows the use of multiple XY records in BOUNDARY elements for unlimited large polygons

Setting this property to true allows big polygons that span over multiple XY records. For strict compatibility with the standard, this property should be set to false. The default is true.

This property has been added in version 0.18.

Python specific notes:
The object exposes a writable attribute 'gds2_allow_multi_xy_records'. This is the setter.

gds2_allow_multi_xy_records?

Signature: *[const]* bool **gds2_allow_multi_xy_records?**

Description: Gets a value specifying whether to allow big polygons with multiple XY records.

See gds2_allow_multi_xy_records= method for a description of this property. This property has been added in version 0.18.

Python specific notes:
The object exposes a readable attribute 'gds2_allow_multi_xy_records'. This is the getter.
This method is available as 'gds2_allow_multi_xy_records_' in Python to distiguish it from the property with the same name.

gds2_box_mode

Signature: *[const]* unsigned int **gds2_box_mode**

Description: Gets a value specifying how to treat BOX records

See gds2_box_mode= method for a description of this mode. This property has been added in version 0.18.

Python specific notes:
The object exposes a readable attribute 'gds2_box_mode'. This is the getter.

gds2_box_mode=

Signature: void **gds2_box_mode=** (unsigned int mode)

Description: Sets a value specifying how to treat BOX records

This property specifies how BOX records are treated. Allowed values are 0 (ignore), 1 (treat as rectangles), 2 (treat as boundaries) or 3 (treat as errors). The default is 1.

This property has been added in version 0.18.

Python specific notes:
The object exposes a writable attribute 'gds2_box_mode'. This is the setter.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_properties_enabled?

Signature: *[const]* bool **is_properties_enabled?**

Description: Gets a value indicating whether properties shall be read

Returns: True, if properties should be read.

Use of this method is deprecated. Use properties_enabled? instead

Starting with version 0.25 this option only applies to GDS2 and OASIS format. Other formats provide their own configuration.

Python specific notes:
The object exposes a readable attribute 'properties_enabled'. This is the getter.

is_text_enabled?

Signature: *[const]* bool **is_text_enabled?**

Description: Gets a value indicating whether text objects shall be read

Returns: True, if text objects should be read.

Use of this method is deprecated. Use text_enabled? instead

Starting with version 0.25 this option only applies to GDS2 and OASIS format. Other formats provide their own configuration.

Python specific notes:
The object exposes a readable attribute 'text_enabled'. This is the getter.

layer_map

Signature: LayerMap **layer_map**

Description: Gets the layer map

Returns: A reference to the layer map

Starting with version 0.25 this option only applies to GDS2 and OASIS format. Other formats provide their own configuration. Python note: this method has been turned into a property in version 0.26.

Python specific notes:
The object exposes a readable attribute 'layer_map'. This is the getter.

layer_map=

Signature: void **layer_map=** (const LayerMap map)

Description: Sets the layer map, but does not affect the "create_other_layers" flag.

map: The layer map to set.

Use create_other_layers? to enable or disable other layers not listed in the layer map.

This convenience method has been introduced with version 0.26.

Python specific notes:

The object exposes a writable attribute 'layer_map'. This is the setter.

lefdef_config

Signature: LEFDEFReaderConfiguration **lefdef_config**

Description: Gets a copy of the LEF/DEF reader configuration

The LEF/DEF reader configuration is wrapped in a separate object of class LEFDEFReaderConfiguration. See there for details. This method will return a copy of the reader configuration. To modify the configuration, modify the copy and set the modified configuration with lefdef_config=.

This method has been added in version 0.25.

Python specific notes:
The object exposes a readable attribute 'lefdef_config'. This is the getter.

lefdef_config=

Signature: void **lefdef_config=** (const LEFDEFReaderConfiguration config)

Description: Sets the LEF/DEF reader configuration

This method has been added in version 0.25.

Python specific notes:
The object exposes a writable attribute 'lefdef_config'. This is the setter.

mag_create_other_layers=

Signature: void **mag_create_other_layers=** (bool create)

Description: Specifies whether other layers shall be created

create: True, if other layers will be created.

See mag_create_other_layers? for a description of this attribute.

This method has been added in version 0.26.2.

Python specific notes:
The object exposes a writable attribute 'mag_create_other_layers'. This is the setter.

mag_create_other_layers?

Signature: *[const]* bool **mag_create_other_layers?**

Description: Gets a value indicating whether other layers shall be created

Returns: True, if other layers will be created.

This attribute acts together with a layer map (see mag_layer_map=). Layers not listed in this map are created as well when mag_create_other_layers? is true. Otherwise they are ignored.

This method has been added in version 0.26.2.

Python specific notes:
The object exposes a readable attribute 'mag_create_other_layers'. This is the getter.

mag_dbu

Signature: *[const]* double **mag_dbu**

Description: Specifies the database unit which the reader uses and produces

See mag_dbu= method for a description of this property.

This property has been added in version 0.26.2.

Python specific notes:
The object exposes a readable attribute 'mag_dbu'. This is the getter.

mag_dbu=

Signature: void **mag_dbu=** (double dbu)

Description: Specifies the database unit which the reader uses and produces

The database unit is the final resolution of the produced layout. This physical resolution is usually defined by the layout system - GDS for example typically uses 1nm (mag_dbu=0.001). All

geometry in the MAG file will first be scaled to mag_lambda and is then brought to the database unit.

This property has been added in version 0.26.2.

Python specific notes:
The object exposes a writable attribute 'mag_dbu'. This is the setter.

mag_keep_layer_names=

Signature: void **mag_keep_layer_names=** (bool keep)

Description: Gets a value indicating whether layer names are kept

keep: True, if layer names are to be kept.

See mag_keep_layer_names? for a description of this property.

This method has been added in version 0.26.2.

Python specific notes:
The object exposes a writable attribute 'mag_keep_layer_names'. This is the setter.

mag_keep_layer_names?

Signature: *[const]* bool **mag_keep_layer_names?**

Description: Gets a value indicating whether layer names are kept

Returns: True, if layer names are kept.

When set to true, no attempt is made to translate layer names to GDS layer/datatype numbers. If set to false (the default), a layer named "L2D15" will be translated to GDS layer 2, datatype 15.

This method has been added in version 0.26.2.

Python specific notes:
The object exposes a readable attribute 'mag_keep_layer_names'. This is the getter.

mag_lambda

Signature: *[const]* double **mag_lambda**

Description: Gets the lambda value

See mag_lambda= method for a description of this attribute.

This property has been added in version 0.26.2.

Python specific notes:
The object exposes a readable attribute 'mag_lambda'. This is the getter.

mag_lambda=

Signature: void **mag_lambda=** (double lambda)

Description: Specifies the lambda value to used for reading

The lambda value is the basic unit of the layout. Magic draws layout as multiples of this basic unit. The layout read by the MAG reader will use the database unit specified by mag_dbu, but the physical layout coordinates will be multiples of mag_lambda.

This property has been added in version 0.26.2.

Python specific notes:
The object exposes a writable attribute 'mag_lambda'. This is the setter.

mag_layer_map

Signature: LayerMap **mag_layer_map**

Description: Gets the layer map

Returns: A reference to the layer map

This method has been added in version 0.26.2.

Python specific notes:
The object exposes a readable attribute 'mag_layer_map'. This is the getter.

mag_layer_map=

Signature: void **mag_layer_map=** (const LayerMap map)

Description: Sets the layer map

map: The layer map to set.

This sets a layer mapping for the reader. Unlike mag_set_layer_map, the 'create_other_layers' flag is not changed.

This method has been added in version 0.26.2.

Python specific notes:
The object exposes a writable attribute 'mag_layer_map'. This is the setter.

mag_library_paths

Signature: *[const]* string[] **mag_library_paths**

Description: Gets the locations where to look up libraries (in this order)

See mag_library_paths= method for a description of this attribute.

This property has been added in version 0.26.2.

Python specific notes:
The object exposes a readable attribute 'mag_library_paths'. This is the getter.

mag_library_paths=

Signature: void **mag_library_paths=** (string[] lib_paths)

Description: Specifies the locations where to look up libraries (in this order)

The reader will look up library reference in these paths when it can't find them locally. Relative paths in this collection are resolved relative to the initial file's path. Expression interpolation is supported in the path strings.

This property has been added in version 0.26.2.

Python specific notes:
The object exposes a writable attribute 'mag_library_paths'. This is the setter.

mag_merge=

Signature: void **mag_merge=** (bool merge)

Description: Sets a value indicating whether boxes are merged into polygons

merge: True, if boxes and triangles will be merged into polygons.

See mag_merge? for a description of this property.

This method has been added in version 0.26.2.

Python specific notes:
The object exposes a writable attribute 'mag_merge'. This is the setter.

mag_merge?

Signature: *[const]* bool **mag_merge?**

Description: Gets a value indicating whether boxes are merged into polygons

Returns: True, if boxes are merged.

When set to true, the boxes and triangles of the Magic layout files are merged into polygons where possible.

This method has been added in version 0.26.2.

Python specific notes:
The object exposes a readable attribute 'mag_merge'. This is the getter.

mag_select_all_layers

Signature: void **mag_select_all_layers**

Description: Selects all layers and disables the layer map

This disables any layer map and enables reading of all layers. New layers will be created when required.

This method has been added in version 0.26.2.

mag_set_layer_map

Signature: void **mag_set_layer_map** (const LayerMap map, bool create_other_layers)

Description: Sets the layer map

map:	The layer map to set.
create_other_layers:	The flag indicating whether other layers will be created as well. Set to false to read only the layers in the layer map.

This sets a layer mapping for the reader. The layer map allows selection and translation of the original layers, for example to assign layer/datatype numbers to the named layers.

This method has been added in version 0.26.2.

new

Signature: *[static]* new LoadLayoutOptions ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

properties_enabled=

Signature: void **properties_enabled=** (bool enabled)

Description: Specifies whether properties should be read

enabled:	True, if properties should be read.

Starting with version 0.25 this option only applies to GDS2 and OASIS format. Other formats provide their own configuration.

Python specific notes:
The object exposes a writable attribute 'properties_enabled'. This is the setter.

properties_enabled?

Signature: *[const]* bool **properties_enabled?**

Description: Gets a value indicating whether properties shall be read

Returns:	True, if properties should be read.

Starting with version 0.25 this option only applies to GDS2 and OASIS format. Other formats provide their own configuration.

Python specific notes:
The object exposes a readable attribute 'properties_enabled'. This is the getter.

select_all_layers

Signature: void **select_all_layers**

Description: Selects all layers and disables the layer map

This disables any layer map and enables reading of all layers. New layers will be created when required.

Starting with version 0.25 this method only applies to GDS2 and OASIS format. Other formats provide their own configuration.

set_layer_map

Signature: void **set_layer_map** (const LayerMap map, bool create_other_layers)

Description: Sets the layer map

map:	The layer map to set.@param create_other_layers The flag telling whether other layer should be created as well. Set to false if just the layers in the mapping table should be read.

This sets a layer mapping for the reader. The layer map allows selection and translation of the original layers, for example to add a layer name.

Starting with version 0.25 this option only applies to GDS2 and OASIS format. Other formats provide their own configuration.

text_enabled=

Signature: void **text_enabled=** (bool enabled)

Description: Specifies whether text objects shall be read

enabled: True, if text objects should be read.

Starting with version 0.25 this option only applies to GDS2 and OASIS format. Other formats provide their own configuration.

Python specific notes:
The object exposes a writable attribute 'text_enabled'. This is the setter.

text_enabled?

Signature: *[const]* bool **text_enabled?**

Description: Gets a value indicating whether text objects shall be read

Returns: True, if text objects should be read.

Starting with version 0.25 this option only applies to GDS2 and OASIS format. Other formats provide their own configuration.

Python specific notes:
The object exposes a readable attribute 'text_enabled'. This is the getter.

warn_level

Signature: *[const]* int **warn_level**

Description: Sets the warning level.

See warn_level= for details about this attribute.

This attribute has been added in version 0.28.

Python specific notes:
The object exposes a readable attribute 'warn_level'. This is the getter.

warn_level=

Signature: void **warn_level=** (int level)

Description: Sets the warning level.

The warning level is a reader-specific setting which enables or disables warnings on specific levels. Level 0 is always "warnings off". The default level is 1 which means "reasonable warnings emitted".

This attribute has been added in version 0.28.

Python specific notes:
The object exposes a writable attribute 'warn_level'. This is the setter.

4.80. API reference - Class LoadLayoutOptions::CellConflictResolution

Notation used in Ruby API documentation

Module: db

Description: This enum specifies how cell conflicts are handled if a layout read into another layout and a cell name conflict arises.

This class is equivalent to the class LoadLayoutOptions::CellConflictResolution

Until version 0.26.8 and before, the mode was always 'AddToCell'. On reading, a cell was 'reopened' when encountering a cell name which already existed. This mode is still the default. The other modes are made available to support other ways of merging layouts.

Proxy cells are never modified in the existing layout. Proxy cells are always local to their layout file. So if the existing cell is a proxy cell, the new cell will be renamed.

If the new or existing cell is a ghost cell, both cells are merged always.

This enum was introduced in version 0.27.

Public constructors

new LoadLayoutOptions::CellConflictResolution ptr	**new**	(int i)	Creates an enum from an integer value
new LoadLayoutOptions::CellConflictResolution ptr	**new**	(string s)	Creates an enum from a string value

Public methods

[const]	bool	**!=**	(const LoadLayoutOptions::CellC other)	Compares two enums for inequality
[const]	bool	**!=**	(int other)	Compares an enum with an integer for inequality
[const]	bool	**<**	(const LoadLayoutOptions::CellC other)	Returns true if the first enum is less (in the enum symbol order) than the second
[const]	bool	**<**	(int other)	Returns true if the enum is less (in the enum symbol order) than the integer value
[const]	bool	**==**	(const LoadLayoutOptions::CellC other)	Compares two enums
[const]	bool	**==**	(int other)	Compares an enum with an integer value
[const]	int	**hash**		Gets the hash value from the enum
[const]	string	**inspect**		Converts an enum to a visual string
[const]	int	**to_i**		Gets the integer value from the enum
[const]	string	**to_s**		Gets the symbolic string from an enum

Public static methods and constants

[static,const]	LoadLayoutOptions::CellConflictRes	**AddToCell**	Add content to existing cell
[static,const]	LoadLayoutOptions::CellConflictResolution	**OverwriteCell**	The old cell is overwritten entirely (including child cells which are not used otherwise)
[static,const]	LoadLayoutOptions::CellConflictRes	**RenameCell**	The new cell will be renamed to become unique
[static,const]	LoadLayoutOptions::CellConflictResolution	**SkipNewCell**	The new cell is skipped entirely (including child cells which are not used otherwise)

Detailed description

!=

(1) Signature: *[const]* bool **!=** (const LoadLayoutOptions::CellConflictResolution other)
Description: Compares two enums for inequality

(2) Signature: *[const]* bool **!=** (int other)
Description: Compares an enum with an integer for inequality

<

(1) Signature: *[const]* bool **<** (const LoadLayoutOptions::CellConflictResolution other)
Description: Returns true if the first enum is less (in the enum symbol order) than the second

(2) Signature: *[const]* bool **<** (int other)
Description: Returns true if the enum is less (in the enum symbol order) than the integer value

==

(1) Signature: *[const]* bool **==** (const LoadLayoutOptions::CellConflictResolution other)
Description: Compares two enums

(2) Signature: *[const]* bool **==** (int other)
Description: Compares an enum with an integer value

AddToCell

Signature: *[static,const]* LoadLayoutOptions::CellConflictResolution **AddToCell**
Description: Add content to existing cell
This is the mode use in before version 0.27. Content of new cells is simply added to existing cells with the same name.
Python specific notes:
The object exposes a readable attribute 'AddToCell'. This is the getter.

OverwriteCell

Signature: *[static,const]* LoadLayoutOptions::CellConflictResolution **OverwriteCell**
Description: The old cell is overwritten entirely (including child cells which are not used otherwise)
Python specific notes:
The object exposes a readable attribute 'OverwriteCell'. This is the getter.

RenameCell

Signature: *[static,const]* LoadLayoutOptions::CellConflictResolution **RenameCell**

Description: The new cell will be renamed to become unique

Python specific notes:
The object exposes a readable attribute 'RenameCell'. This is the getter.

SkipNewCell

Signature: *[static,const]* LoadLayoutOptions::CellConflictResolution **SkipNewCell**

Description: The new cell is skipped entirely (including child cells which are not used otherwise)

Python specific notes:
The object exposes a readable attribute 'SkipNewCell'. This is the getter.

hash

Signature: *[const]* int **hash**

Description: Gets the hash value from the enum

Python specific notes:
This method is also available as 'hash(object)'.

inspect

Signature: *[const]* string **inspect**

Description: Converts an enum to a visual string

Python specific notes:
This method is also available as 'repr(object)'.

new

(1) Signature: *[static]* new LoadLayoutOptions::CellConflictResolution ptr **new** (int i)

Description: Creates an enum from an integer value

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new LoadLayoutOptions::CellConflictResolution ptr **new** (string s)

Description: Creates an enum from a string value

Python specific notes:
This method is the default initializer of the object.

to_i

Signature: *[const]* int **to_i**

Description: Gets the integer value from the enum

Python specific notes:
This method is also available as 'int(object)'.

to_s

Signature: *[const]* string **to_s**

Description: Gets the symbolic string from an enum

Python specific notes:
This method is also available as 'str(object)'.

4.81. API reference - Class RecursiveInstanceIterator

Notation used in Ruby API documentation

Module: db

Description: An iterator delivering instances recursively

The iterator can be obtained from a cell and optionally a region. It simplifies retrieval of instances while considering subcells as well. Some options can be specified in addition, i.e. the hierarchy level to which to look into. The search can be confined to instances of certain cells (see targets=) or to certain regions. Subtrees can be selected for traversal or excluded from it (see select_cells).

This is some sample code:

```
# prints the effective instances of cell "A" as seen from the initial cell "cell"
iter = cell.begin_instances_rec
iter.targets = "A"
while !iter.at_end?
  puts "Instance of #{iter.inst_cell.name} in #{cell.name}: " + (iter.dtrans * iter.inst_dtrans).to_s
  iter.next
end

# or shorter:
cell.begin_instances_rec.each do |iter|
  puts "Instance of #{iter.inst_cell.name} in #{cell.name}: " + (iter.dtrans * iter.inst_dtrans).to_s
end
```

Here, a target cell is specified which confines the search to instances of this particular cell. 'iter.dtrans' gives us the accumulated transformation of all parents up to the top cell. 'iter.inst_dtrans' gives us the transformation from the current instance. 'iter.inst_cell' finally gives us the target cell of the current instance (which is always 'A' in our case).

Cell offers three methods to get these iterators: begin_instances_rec, begin_instances_rec_touching and begin_instances_rec_overlapping. Cell#begin_instances_rec will deliver a standard recursive instance iterator which starts from the given cell and iterates over all child cells. Cell#begin_instances_rec_touching creates a RecursiveInstanceIterator which delivers the instances whose bounding boxed touch the given search box. Cell#begin_instances_rec_overlapping gives an iterator which delivers all instances whose bounding box overlaps the search box.

A RecursiveInstanceIterator object can also be created directly, like this:

```
iter = RBA::RecursiveInstanceIterator::new(layout, cell [, options ])
```

"layout" is the layout object, "cell" the Cell object of the initial cell.

The recursive instance iterator can be confined to a maximum hierarchy depth. By using max_depth=, the iterator will restrict the search depth to the given depth in the cell tree. In the same way, the iterator can be configured to start from a certain hierarchy depth using min_depth=. The hierarchy depth always applies to the parent of the instances iterated.

In addition, the recursive instance iterator supports selection and exclusion of subtrees. For that purpose it keeps flags per cell telling it for which cells to turn instance delivery on and off. The select_cells method sets the "start delivery" flag while unselect_cells sets the "stop delivery" flag. In effect, using unselect_cells will exclude that cell plus the subtree from delivery. Parts of that subtree can be turned on again using select_cells. For the cells selected that way, the instances of these cells and their child cells are delivered, even if their parent was unselected.

To get instances from a specific cell, i.e. "MACRO" plus its child cells, unselect the top cell first and the select the desired cell again:

```
# deliver all instances inside "MACRO" and the sub-hierarchy:
iter = RBA::RecursiveInstanceIterator::new(layout, cell)
iter.unselect_cells(cell.cell_index)
iter.select_cells("MACRO")
```

```
...
```

The unselect_all_cells and select_all_cells methods turn on the "stop" and "start" flag for all cells respectively. If you use unselect_all_cells and use select_cells for a specific cell, the iterator will deliver only the instances of the selected cell, not its children. Those are still unselected by unselect_all_cells:

```
# deliver all instance inside "MACRO" but not of child cells:
iter = RBA::RecursiveInstanceIterator::new(layout, cell)
iter.unselect_all_cells
iter.select_cells("MACRO")
...
```

Cell selection is done using cell indexes or glob pattern. Glob pattern are equivalent to the usual file name wildcards used on various command line shells. For example "A*" matches all cells starting with an "A". The curly brace notation and character classes are supported as well. For example "C{125,512}" matches "C125" and "C512" and "[ABC]*" matches all cells starting with an "A", a "B" or "C". "[^ABC]*" matches all cells not starting with one of that letters.

To confine instance iteration to instances of certain cells, use the targets feature:

```
# deliver all instance of "INV1":
iter = RBA::RecursiveInstanceIterator::new(layout, cell)
iter.targets = "INV1"
...
```

Targets can be specified either as lists of cell indexes or through a glob pattern.

Instances are always delivered depth-first with child instances before their parents. A default recursive instance iterator will first deliver leaf cells, followed by the parent of these cells.

When a search region is used, instances whose bounding box touch or overlap (depending on 'overlapping' flag) will be reported. The instance bounding box taken as reference is computed using all layers of the layout.

The iterator will deliver the individual elements of instance arrays, confined to the search region if one is given. Consequently the return value (current_inst_element) is an InstElement object which is basically a combination of an Instance object and information about the current array element. inst_cell, inst_trans and inst_dtrans are methods provided for convenience to access the current array member's transformation and the target cell of the current instance.

The RecursiveInstanceIterator class has been introduced in version 0.27.

Public constructors

new RecursiveInstanceIterator ptr	**new**	(const Layout layout, const Cell cell)	Creates a recursive instance iterator.
new RecursiveInstanceIterator ptr	**new**	(const Layout layout, const Cell cell, const Box box, bool overlapping = false)	Creates a recursive instance iterator with a search region.
new RecursiveInstanceIterator ptr	**new**	(const Layout layout, const Cell cell, const Region region, bool overlapping)	Creates a recursive instance iterator with a search region.

Public methods

[const]	bool	**!=**	(const RecursiveInstar other)	Comparison of iterators - inequality
[const]	bool	**==**	(const RecursiveInstanceIterator other)	Comparison of iterators - equality
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	bool	**all_targets_enabled?**		Gets a value indicating whether instances of all cells are reported
	void	**assign**	(const RecursiveInstanceIterator other)	Assigns another object to self
[const]	bool	**at_end?**		End of iterator predicate
[const]	const Cell ptr	**cell**		Gets the cell the current instance sits in
[const]	unsigned int	**cell_index**		Gets the index of the cell the current instance sits in
[const]	Region	**complex_region**		Gets the complex region that this iterator is using
	void	**confine_region**	(const Box box_region)	Confines the region that this iterator is iterating over
	void	**confine_region**	(const Region complex_region)	Confines the region that this iterator is iterating over
[const]	InstElement	**current_inst_element**		Gets the current instance
[const]	DCplxTrans	**dtrans**		Gets the accumulated transformation of the current instance parent cell to the top cell
[const]	new RecursiveInstanceItera ptr	**dup**		Creates a copy of self

[iter]	RecursiveInstanceIterator	**each**		Native iteration
	void	**enable_all_targets**		Enables 'all targets' mode in which instances of all cells are reported
[const]	Cell ptr	**inst_cell**		Gets the target cell of the current instance
[const]	DCplxTrans	**inst_dtrans**		Gets the micron-unit transformation of the current instance
[const]	ICplxTrans	**inst_trans**		Gets the integer-unit transformation of the current instance
[const]	const Layout ptr	**layout**		Gets the layout this iterator is connected to
[const]	int	**max_depth**		Gets the maximum hierarchy depth
	void	**max_depth=**	(int depth)	Specifies the maximum hierarchy depth to look into
[const]	int	**min_depth**		Gets the minimum hierarchy depth
	void	**min_depth=**	(int depth)	Specifies the minimum hierarchy depth to look into
	void	**next**		Increments the iterator
	void	**overlapping=**	(bool region)	Sets a flag indicating whether overlapping instances are selected when a region is used
[const]	bool	**overlapping?**		Gets a flag indicating whether overlapping instances are selected when a region is used
[const]	InstElement[]	**path**		Gets the instantiation path of the instance addressed currently
[const]	Box	**region**		Gets the basic region that this iterator is using
	void	**region=**	(const Box box_region)	Sets the rectangular region that this iterator is iterating over
	void	**region=**	(const Region complex_region)	Sets the complex region that this iterator is using
	void	**reset**		Resets the iterator to the initial state
	void	**reset_selection**		Resets the selection to the default state
	void	**select_all_cells**		Selects all cells.
	void	**select_cells**	(unsigned int[] cells)	Unselects the given cells.
	void	**select_cells**	(string cells)	Unselects the given cells.
[const]	unsigned int[]	**targets**		Gets the list of target cells

	void	**targets=**	(unsigned int[] cells)	Specifies the target cells.
	void	**targets=**	(string cells)	Specifies the target cells.
[const]	const Cell ptr	**top_cell**		Gets the top cell this iterator is connected to
[const]	ICplxTrans	**trans**		Gets the accumulated transformation of the current instance parent cell to the top cell
	void	**unselect_all_cells**		Unselects all cells.
	void	**unselect_cells**	(unsigned int[] cells)	Unselects the given cells.
	void	**unselect_cells**	(string cells)	Unselects the given cells.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

!=

Signature: *[const]* bool **!=** (const RecursiveInstanceIterator other)

Description: Comparison of iterators - inequality

Two iterators are not equal if they do not point to the same instance.

==

Signature: *[const]* bool **==** (const RecursiveInstanceIterator other)

Description: Comparison of iterators - equality

Two iterators are equal if they point to the same instance.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

all_targets_enabled?

Signature: *[const]* bool **all_targets_enabled?**

Description: Gets a value indicating whether instances of all cells are reported

See targets= for a description of the target cell concept.

assign

Signature: void **assign** (const RecursiveInstanceIterator other)

Description: Assigns another object to self

at_end?

Signature: *[const]* bool **at_end?**

Description: End of iterator predicate

Returns true, if the iterator is at the end of the sequence

cell

Signature: *[const]* const Cell ptr **cell**

Description: Gets the cell the current instance sits in

cell_index

Signature: *[const]* unsigned int **cell_index**

Description: Gets the index of the cell the current instance sits in

This is equivalent to 'cell.cell_index'.

complex_region

Signature: *[const]* Region **complex_region**

Description: Gets the complex region that this iterator is using

The complex region is the effective region (a Region object) that the iterator is selecting from the layout. This region can be a single box or a complex region.

confine_region

(1) Signature: void **confine_region** (const Box box_region)

Description: Confines the region that this iterator is iterating over

This method is similar to setting the region (see region=), but will confine any region (complex or simple) already set. Essentially it does a logical AND operation between the existing and given region. Hence this method can only reduce a region, not extend it.

(2) Signature: void **confine_region** (const Region complex_region)

Description: Confines the region that this iterator is iterating over

This method is similar to setting the region (see region=), but will confine any region (complex or simple) already set. Essentially it does a logical AND operation between the existing and given region. Hence this method can only reduce a region, not extend it.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

current_inst_element

Signature: *[const]* InstElement **current_inst_element**

Description: Gets the current instance

This is the instance/array element the iterator currently refers to. This is a InstElement object representing the current instance and the array element the iterator currently points at.

See inst_trans, inst_dtrans and inst_cell for convenience methods to access the details of the current element.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dtrans

Signature: *[const]* DCplxTrans **dtrans**

Description: Gets the accumulated transformation of the current instance parent cell to the top cell

This transformation represents how the current instance is seen in the top cell. This version returns the micron-unit transformation.

dup

Signature: *[const]* new RecursiveInstanceIterator ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

each

Signature: *[iter]* RecursiveInstanceIterator **each**

Description: Native iteration

This method enables native iteration, e.g.

```
iter = ... # RecursiveInstanceIterator
iter.each do |i|
   ... i is the iterator itself
end
```

This is slightly more convenient than the 'at_end' .. 'next' loop.

This feature has been introduced in version 0.28.

Python specific notes:
This method enables iteration of the object.

enable_all_targets

Signature: void **enable_all_targets**

Description: Enables 'all targets' mode in which instances of all cells are reported

See targets= for a description of the target cell concept.

inst_cell

Signature: *[const]* Cell ptr **inst_cell**

Description: Gets the target cell of the current instance

This is the cell the current instance refers to. It is one of the targets if a target list is given.

inst_dtrans

Signature: *[const]* DCplxTrans **inst_dtrans**

Description: Gets the micron-unit transformation of the current instance

This is the transformation of the current instance inside its parent. 'dtrans * inst_dtrans' gives the full micron-unit transformation how the current cell is seen in the top cell. See also inst_trans and inst_cell.

inst_trans

Signature: *[const]* ICplxTrans **inst_trans**

Description: Gets the integer-unit transformation of the current instance

This is the transformation of the current instance inside its parent. 'trans * inst_trans' gives the full transformation how the current cell is seen in the top cell. See also inst_dtrans and inst_cell.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

layout

Signature: *[const]* const Layout ptr **layout**

Description: Gets the layout this iterator is connected to

max_depth

Signature: *[const]* int **max_depth**

Description: Gets the maximum hierarchy depth

See max_depth= for a description of that attribute.

Python specific notes:
The object exposes a readable attribute 'max_depth'. This is the getter.

max_depth=

Signature: void **max_depth=** (int depth)

Description: Specifies the maximum hierarchy depth to look into

A depth of 0 instructs the iterator to deliver only instances from the initial cell. A higher depth instructs the iterator to look deeper. The depth must be specified before the instances are being retrieved.

Python specific notes:
The object exposes a writable attribute 'max_depth'. This is the setter.

min_depth

Signature: *[const]* int **min_depth**

Description: Gets the minimum hierarchy depth

See min_depth= for a description of that attribute.

Python specific notes:
The object exposes a readable attribute 'min_depth'. This is the getter.

min_depth=

Signature: void **min_depth=** (int depth)

Description: Specifies the minimum hierarchy depth to look into

A depth of 0 instructs the iterator to deliver instances from the top level. 1 instructs to deliver instances from the first child level. The minimum depth must be specified before the instances are being retrieved.

Python specific notes:
The object exposes a writable attribute 'min_depth'. This is the setter.

new

(1) Signature: *[static]* new RecursiveInstanceIterator ptr **new** (const Layout layout, const Cell cell)

Description: Creates a recursive instance iterator.

layout:	The layout which shall be iterated
cell:	The initial cell which shall be iterated (including its children)
layer:	The layer (index) from which the shapes are taken

This constructor creates a new recursive instance iterator which delivers the instances of the given cell plus its children.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new RecursiveInstanceIterator ptr **new** (const Layout layout, const Cell cell, const Box box, bool overlapping = false)

Description: Creates a recursive instance iterator with a search region.

layout:	The layout which shall be iterated

cell:	The initial cell which shall be iterated (including its children)
box:	The search region
overlapping:	If set to true, instances overlapping the search region are reported, otherwise touching is sufficient

This constructor creates a new recursive instance iterator which delivers the instances of the given cell plus its children.

The search is confined to the region given by the "box" parameter. If "overlapping" is true, instances whose bounding box is overlapping the search region are reported. If "overlapping" is false, instances whose bounding box touches the search region are reported. The bounding box of instances is measured taking all layers of the target cell into account.

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new RecursiveInstanceIterator ptr **new** (const Layout layout, const Cell cell, const Region region, bool overlapping)

Description: Creates a recursive instance iterator with a search region.

layout:	The layout which shall be iterated
cell:	The initial cell which shall be iterated (including its children)
region:	The search region
overlapping:	If set to true, instances overlapping the search region are reported, otherwise touching is sufficient

This constructor creates a new recursive instance iterator which delivers the instances of the given cell plus its children.

The search is confined to the region given by the "region" parameter. The region needs to be a rectilinear region. If "overlapping" is true, instances whose bounding box is overlapping the search region are reported. If "overlapping" is false, instances whose bounding box touches the search region are reported. The bounding box of instances is measured taking all layers of the target cell into account.

Python specific notes:
This method is the default initializer of the object.

next

Signature: void **next**

Description: Increments the iterator

This moves the iterator to the next instance inside the search scope.

overlapping=

Signature: void **overlapping=** (bool region)

Description: Sets a flag indicating whether overlapping instances are selected when a region is used

If this flag is false, instances touching the search region are returned.

Python specific notes:
The object exposes a writable attribute 'overlapping'. This is the setter.

overlapping?

Signature: *[const]* bool **overlapping?**

Description: Gets a flag indicating whether overlapping instances are selected when a region is used

Python specific notes:
The object exposes a readable attribute 'overlapping'. This is the getter.

path

Signature: *[const]* InstElement[] **path**

Description: Gets the instantiation path of the instance addressed currently

This attribute is a sequence of InstElement objects describing the cell instance path from the initial cell to the current instance. The path is empty if the current instance is in the top cell.

region

Signature: *[const]* Box **region**

Description: Gets the basic region that this iterator is using

The basic region is the overall box the region iterator iterates over. There may be an additional complex region that confines the region iterator. See complex_region for this attribute.

Python specific notes:
The object exposes a readable attribute 'region'. This is the getter.

region=

(1) Signature: void **region=** (const Box box_region)

Description: Sets the rectangular region that this iterator is iterating over

See region for a description of this attribute. Setting a simple region will reset the complex region to a rectangle and reset the iterator to the beginning of the sequence.

Python specific notes:
The object exposes a writable attribute 'region'. This is the setter.

(2) Signature: void **region=** (const Region complex_region)

Description: Sets the complex region that this iterator is using

See complex_region for a description of this attribute. Setting the complex region will reset the basic region (see region) to the bounding box of the complex region and reset the iterator to the beginning of the sequence.

Python specific notes:
The object exposes a writable attribute 'region'. This is the setter.

reset

Signature: void **reset**

Description: Resets the iterator to the initial state

reset_selection

Signature: void **reset_selection**

Description: Resets the selection to the default state

In the initial state, the top cell and its children are selected. Child cells can be switched on and off together with their sub-hierarchy using select_cells and unselect_cells.

This method will also reset the iterator.

select_all_cells

Signature: void **select_all_cells**

Description: Selects all cells.

This method will set the "selected" mark on all cells. The effect is that subsequent calls of unselect_cells will unselect only the specified cells, not their children, because they are still unselected.

This method will also reset the iterator.

select_cells

(1) Signature: void **select_cells** (unsigned int[] cells)

Description: Unselects the given cells.

This method will sets the "selected" mark on the given cells. That means that these cells or their child cells are visited, unless they are marked as "unselected" again with the unselect_cells method.

The cells are given as a list of cell indexes.

This method will also reset the iterator.

(2) Signature: void **select_cells** (string cells)

Description: Unselects the given cells.

This method will sets the "selected" mark on the given cells. That means that these cells or their child cells are visited, unless they are marked as "unselected" again with the unselect_cells method.

The cells are given as a glob pattern. A glob pattern follows the syntax of file names on the shell (i.e. "A*" are all cells starting with a letter "A").

This method will also reset the iterator.

targets

Signature: *[const]* unsigned int[] **targets**

Description: Gets the list of target cells

See targets= for a description of the target cell concept. This method returns a list of cell indexes of the selected target cells.

Python specific notes:
The object exposes a readable attribute 'targets'. This is the getter.

targets=

(1) Signature: void **targets=** (unsigned int[] cells)

Description: Specifies the target cells.

If target cells are specified, only instances of these cells are delivered. This version takes a list of cell indexes for the targets. By default, no target cell list is present and the instances of all cells are delivered by the iterator. See all_targets_enabled? and enable_all_targets for a description of this mode. Once a target list is specified, the iteration is confined to the cells from this list. The cells are given as a list of cell indexes.

This method will also reset the iterator.

Python specific notes:
The object exposes a writable attribute 'targets'. This is the setter.

(2) Signature: void **targets=** (string cells)

Description: Specifies the target cells.

If target cells are specified, only instances of these cells are delivered. This version takes a cell list as a glob pattern. A glob pattern follows the syntax of file names on the shell (i.e. "A*" are all cells starting with a letter "A"). Use the curly-bracket notation to list different cells, e.g "{A,B,C}" for cells A, B and C.

By default, no target cell list is present and the instances of all cells are delivered by the iterator. See all_targets_enabled? and enable_all_targets for a description of this mode. Once a target list is specified, the iteration is confined to the cells from this list. The cells are given as a list of cell indexes.

This method will also reset the iterator.

Python specific notes:
The object exposes a writable attribute 'targets'. This is the setter.

top_cell

Signature: *[const]* const Cell ptr **top_cell**

Description: Gets the top cell this iterator is connected to

trans

Signature: *[const]* ICplxTrans **trans**

Description: Gets the accumulated transformation of the current instance parent cell to the top cell

This transformation represents how the current instance is seen in the top cell.

unselect_all_cells

Signature: void **unselect_all_cells**

Description: Unselects all cells.

This method will set the "unselected" mark on all cells. The effect is that subsequent calls of select_cells will select only the specified cells, not their children, because they are still unselected.

This method will also reset the iterator.

unselect_cells

(1) Signature: void **unselect_cells** (unsigned int[] cells)

Description: Unselects the given cells.

This method will sets the "unselected" mark on the given cells. That means that these cells or their child cells will not be visited, unless they are marked as "selected" again with the select_cells method.

The cells are given as a list of cell indexes.

This method will also reset the iterator.

(2) Signature: void **unselect_cells** (string cells)

Description: Unselects the given cells.

This method will sets the "unselected" mark on the given cells. That means that these cells or their child cells will not be visited, unless they are marked as "selected" again with the select_cells method.

The cells are given as a glob pattern. A glob pattern follows the syntax of file names on the shell (i.e. "A*" are all cells starting with a letter "A").

This method will also reset the iterator.

4.82. API reference - Class RecursiveShapeIterator

Notation used in Ruby API documentation

Module: db

Description: An iterator delivering shapes recursively

The iterator can be obtained from a cell, a layer and optionally a region. It simplifies retrieval of shapes from a geometrical region while considering subcells as well. Some options can be specified in addition, i.e. the level to which to look into or shape classes and shape properties. The shapes are retrieved by using the shape method, next moves to the next shape and at_end tells, if the iterator has move shapes to deliver.

This is some sample code:

```
# print the polygon-like objects as seen from the initial cell "cell"
iter = cell.begin_shapes_rec(layer)
while !iter.at_end?
  if iter.shape.renders_polygon?
    polygon = iter.shape.polygon.transformed(iter.itrans)
    puts "In cell #{iter.cell.name}: " + polygon.to_s
  end
  iter.next
end

# or shorter:
cell.begin_shapes_rec(layer).each do |iter|
  if iter.shape.renders_polygon?
    polygon = iter.shape.polygon.transformed(iter.itrans)
    puts "In cell #{iter.cell.name}: " + polygon.to_s
  end
end
```

Cell offers three methods to get these iterators: begin_shapes_rec, begin_shapes_rec_touching and begin_shapes_rec_overlapping. Cell#begin_shapes_rec will deliver a standard recursive shape iterator which starts from the given cell and iterates over all child cells. Cell#begin_shapes_rec_touching delivers a RecursiveShapeIterator which delivers the shapes whose bounding boxed touch the given search box. Cell#begin_shapes_rec_overlapping delivers all shapes whose bounding box overlaps the search box.

A RecursiveShapeIterator object can also be created explicitly. This allows some more options, i.e. using multiple layers. A multi-layer recursive shape iterator can be created like this:

```
iter = RBA::RecursiveShapeIterator::new(layout, cell, [ layer_index1, layer_index2 .. ])
```

"layout" is the layout object, "cell" the RBA::Cell object of the initial cell. layer_index1 etc. are the layer indexes of the layers to get the shapes from. While iterating, RecursiveShapeIterator#layer delivers the layer index of the current shape.

The recursive shape iterator can be confined to a maximum hierarchy depth. By using max_depth=, the iterator will restrict the search depth to the given depth in the cell tree.

In addition, the recursive shape iterator supports selection and exclusion of subtrees. For that purpose it keeps flags per cell telling it for which cells to turn shape delivery on and off. The select_cells method sets the "start delivery" flag while unselect_cells sets the "stop delivery" flag. In effect, using unselect_cells will exclude that cell plus the subtree from delivery. Parts of that subtree can be turned on again using select_cells. For the cells selected that way, the shapes of these cells and their child cells are delivered, even if their parent was unselected.

To get shapes from a specific cell, i.e. "MACRO" plus its child cells, unselect the top cell first and the select the desired cell again:

```
# deliver all shapes inside "MACRO" and the sub-hierarchy:
iter = RBA::RecursiveShapeIterator::new(layout, cell, layer)
iter.unselect_cells(cell.cell_index)
```

```
iter.select_cells("MACRO")
```

Note that if "MACRO" uses library cells for example which are used otherwise as well, the iterator will only deliver the shapes for those instances belonging to "MACRO" (directly or indirectly), not those for other instances of these library cells.

The unselect_all_cells and select_all_cells methods turn on the "stop" and "start" flag for all cells respectively. If you use unselect_all_cells and use select_cells for a specific cell, the iterator will deliver only the shapes of the selected cell, not its children. Those are still unselected by unselect_all_cells:

```
# deliver all shapes of "MACRO" but not of child cells:
iter = RBA::RecursiveShapeIterator::new(layout, cell, layer)
iter.unselect_all_cells
iter.select_cells("MACRO")
```

Cell selection is done using cell indexes or glob pattern. Glob pattern are equivalent to the usual file name wildcards used on various command line shells. For example "A*" matches all cells starting with an "A". The curly brace notation and character classes are supported as well. For example "C{125,512}" matches "C125" and "C512" and "[ABC]*" matches all cells starting with an "A", a "B" or "C". "[^ABC]*" matches all cells not starting with one of that letters.

The RecursiveShapeIterator class has been introduced in version 0.18 and has been extended substantially in 0.23.

Public constructors

new RecursiveShapeIterator ptr	**new**	(const Layout layout, const Cell cell, unsigned int layer)	Creates a recursive, single-layer shape iterator.
new RecursiveShapeIterator ptr	**new**	(const Layout layout, const Cell cell, unsigned int[] layers)	Creates a recursive, multi-layer shape iterator.
new RecursiveShapeIterator ptr	**new**	(const Layout layout, const Cell cell, unsigned int layer, const Box box, bool overlapping = false)	Creates a recursive, single-layer shape iterator with a region.
new RecursiveShapeIterator ptr	**new**	(const Layout layout, const Cell cell, unsigned int layer, const Region region, bool overlapping = false)	Creates a recursive, single-layer shape iterator with a region.
new RecursiveShapeIterator ptr	**new**	(const Layout layout, const Cell cell, unsigned int[] layers, const Box box, bool overlapping = false)	Creates a recursive, multi-layer shape iterator with a region.
new RecursiveShapeIterator ptr	**new**	(const Layout layout, const Cell cell, unsigned int[] layers, const Region region, bool overlapping = false)	Creates a recursive, multi-layer shape iterator with a region.

Public methods

[const]	bool	**!=**	(const RecursiveShape other)	Comparison of iterators - inequality
[const]	bool	**==**	(const RecursiveShapeIterator other)	Comparison of iterators - equality
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	DCplxTrans	**always_apply_dtrans**		Gets the global transformation if at top level, unity otherwise (micrometer-unit version)
[const]	ICplxTrans	**always_apply_trans**		Gets the global transformation if at top level, unity otherwise
	void	**assign**	(const RecursiveShape other)	Assigns another object to self
[const]	bool	**at_end?**		End of iterator predicate
[const]	const Cell ptr	**cell**		Gets the current cell's object
[const]	unsigned int	**cell_index**		Gets the current cell's index
[const]	Region	**complex_region**		Gets the complex region that this iterator is using
	void	**confine_region**	(const Box box_region)	Confines the region that this iterator is iterating over
	void	**confine_region**	(const Region complex_region)	Confines the region that this iterator is iterating over
[const]	DCplxTrans	**dtrans**		Gets the transformation into the initial cell applicable for floating point types
[const]	new RecursiveShapeIterator ptr	**dup**		Creates a copy of self
[iter]	RecursiveShapeIterator	**each**		Native iteration

	void	**enable_properties**		Enables properties for the given iterator.
	void	**filter_properties**	(variant[] keys)	Filters properties by certain keys.
	void	**for_merged_input=**	(bool flag)	Sets a flag indicating whether iterator optimizes for merged input
[const]	bool	**for_merged_input?**		Gets a flag indicating whether iterator optimizes for merged input
[const]	DCplxTrans	**global_dtrans**		Gets the global transformation to apply to all shapes delivered (in micrometer units)
	void	**global_dtrans=**	(const DCplxTrans t)	Sets the global transformation to apply to all shapes delivered (transformation in micrometer units)
[const]	ICplxTrans	**global_trans**		Gets the global transformation to apply to all shapes delivered
	void	**global_trans=**	(const ICplxTrans t)	Sets the global transformation to apply to all shapes delivered
[const]	unsigned int	**layer**		Returns the layer index where the current shape is coming from.
[const]	const Layout ptr	**layout**		Gets the layout this iterator is connected to
	void	**map_properties**	(map<variant,va key_map)	Maps properties by name key.
[const]	int	**max_depth**		Gets the maximum hierarchy depth
	void	**max_depth=**	(int depth)	Specifies the maximum hierarchy depth to look into
[const]	int	**min_depth**		Gets the minimum hierarchy depth
	void	**min_depth=**	(int depth)	Specifies the minimum hierarchy depth to look into
	void	**next**		Increments the iterator
	void	**overlapping=**	(bool flag)	Sets a flag indicating whether overlapping shapes are selected when a region is used
[const]	bool	**overlapping?**		Gets a flag indicating whether overlapping shapes are selected when a region is used
[const]	InstElement[]	**path**		Gets the instantiation path of the shape addressed currently
[const]	unsigned long	**prop_id**		Gets the effective properties ID
[const]	Box	**region**		Gets the basic region that this iterator is using

	void	**region=**	(const Box box_region)	Sets the rectangular region that this iterator is iterating over
	void	**region=**	(const Region complex_region)	Sets the complex region that this iterator is using
	void	**remove_properties**		Removes properties for the given container.
	void	**reset**		Resets the iterator to the initial state
	void	**reset_selection**		Resets the selection to the default state
	void	**select_all_cells**		Selects all cells.
	void	**select_cells**	(unsigned int[] cells)	Unselects the given cells.
	void	**select_cells**	(string cells)	Unselects the given cells.
[const]	Shape	**shape**		Gets the current shape
[const]	unsigned int	**shape_flags**		Gets the shape selection flags
	void	**shape_flags=**	(unsigned int flags)	Specifies the shape selection flags
[const]	const Cell ptr	**top_cell**		Gets the top cell this iterator is connected to
[const]	ICplxTrans	**trans**		Gets the current transformation by which the shapes must be transformed into the initial cell
	void	**unselect_all_cells**		Unselects all cells.
	void	**unselect_cells**	(unsigned int[] cells)	Unselects the given cells.
	void	**unselect_cells**	(string cells)	Unselects the given cells.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead
[const]	ICplxTrans	**itrans**	Use of this method is deprecated. Use trans instead

Detailed description

!=

Signature: *[const]* bool **!=** (const RecursiveShapeIterator other)
Description: Comparison of iterators - inequality

	Two iterators are not equal if they do not point to the same shape.
==	**Signature**: *[const]* bool **==** (const RecursiveShapeIterator other) **Description**: Comparison of iterators - equality Two iterators are equal if they point to the same shape.
_create	**Signature**: void **_create** **Description**: Ensures the C++ object is created Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
_destroy	**Signature**: void **_destroy** **Description**: Explicitly destroys the object Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
_destroyed?	**Signature**: *[const]* bool **_destroyed?** **Description**: Returns a value indicating whether the object was already destroyed This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
_is_const_object?	**Signature**: *[const]* bool **_is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference This method returns true, if self is a const reference. In that case, only const methods may be called on self.
_manage	**Signature**: void **_manage** **Description**: Marks the object as managed by the script side. After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required. Usually it's not required to call this method. It has been introduced in version 0.24.
_unmanage	**Signature**: void **_unmanage** **Description**: Marks the object as no longer owned by the script side. Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.

always_apply_dtrans

Signature: *[const]* DCplxTrans **always_apply_dtrans**

Description: Gets the global transformation if at top level, unity otherwise (micrometer-unit version)

As the global transformation is only applicable on top level, use this method to transform shapes and instances into their local (cell-level) version while considering the global transformation properly.

This method has been introduced in version 0.27.

always_apply_trans

Signature: *[const]* ICplxTrans **always_apply_trans**

Description: Gets the global transformation if at top level, unity otherwise

As the global transformation is only applicable on top level, use this method to transform shapes and instances into their local (cell-level) version while considering the global transformation properly.

This method has been introduced in version 0.27.

assign

Signature: void **assign** (const RecursiveShapeIterator other)

Description: Assigns another object to self

at_end?

Signature: *[const]* bool **at_end?**

Description: End of iterator predicate

Returns true, if the iterator is at the end of the sequence

cell

Signature: *[const]* const Cell ptr **cell**

Description: Gets the current cell's object

This method has been introduced in version 0.23.

cell_index

Signature: *[const]* unsigned int **cell_index**

Description: Gets the current cell's index

complex_region

Signature: *[const]* Region **complex_region**

Description: Gets the complex region that this iterator is using

The complex region is the effective region (a Region object) that the iterator is selecting from the layout layers. This region can be a single box or a complex region.

This method has been introduced in version 0.25.

confine_region

(1) Signature: void **confine_region** (const Box box_region)

Description: Confines the region that this iterator is iterating over

This method is similar to setting the region (see region=), but will confine any region (complex or simple) already set. Essentially it does a logical AND operation between the existing and given region. Hence this method can only reduce a region, not extend it.

This method has been introduced in version 0.25.

(2) Signature: void **confine_region** (const Region complex_region)

Description: Confines the region that this iterator is iterating over

This method is similar to setting the region (see region=), but will confine any region (complex or simple) already set. Essentially it does a logical AND operation between the existing and given region. Hence this method can only reduce a region, not extend it.

This method has been introduced in version 0.25.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dtrans

Signature: *[const]* DCplxTrans **dtrans**

Description: Gets the transformation into the initial cell applicable for floating point types

This transformation corresponds to the one delivered by trans, but is applicable for the floating-point shape types in micron unit space.

This method has been introduced in version 0.25.3.

dup

Signature: *[const]* new RecursiveShapeIterator ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

each

Signature: *[iter]* RecursiveShapeIterator **each**

Description: Native iteration

This method enables native iteration, e.g.

```
iter = ... # RecursiveShapeIterator
iter.each do |i|
   ... i is the iterator itself
end
```

This is slightly more convenient than the 'at_end' .. 'next' loop.

This feature has been introduced in version 0.28.

Python specific notes:
This method enables iteration of the object.

enable_properties

Signature: void **enable_properties**

Description: Enables properties for the given iterator.

Afer enabling properties, prop_id will deliver the effective properties ID for the current shape.
By default, properties are not enabled and prop_id will always return 0 (no properties attached).
Alternatively you can apply filter_properties or map_properties to enable properties with a specific name key.

Note that property filters/mappers are additive and act in addition (after) the currently installed filter.

This feature has been introduced in version 0.28.4.

filter_properties

Signature: void **filter_properties** (variant[] keys)

Description: Filters properties by certain keys.

Calling this method will reduce the properties to values with name keys from the 'keys' list. As a side effect, this method enables properties. As with enable_properties or remove_properties, this filter has an effect on the value returned by prop_id, not on the properties ID attached to the shape directly.

Note that property filters/mappers are additive and act in addition (after) the currently installed filter.

This feature has been introduced in version 0.28.4.

for_merged_input=

Signature: void **for_merged_input=** (bool flag)

Description: Sets a flag indicating whether iterator optimizes for merged input

If this flag is set to true, the iterator is allowed to skip shapes it deems irrelevant because they are covered entirely by other shapes. This allows shortcutting hierarchy traversal in some cases.

This method has been introduced in version 0.29.

Python specific notes:
The object exposes a writable attribute 'for_merged_input'. This is the setter.

for_merged_input?

Signature: *[const]* bool **for_merged_input?**

Description: Gets a flag indicating whether iterator optimizes for merged input

see for_merged_input= for details of this attribute.

This method has been introduced in version 0.29.

Python specific notes:
The object exposes a readable attribute 'for_merged_input'. This is the getter.

global_dtrans

Signature: *[const]* DCplxTrans **global_dtrans**

Description: Gets the global transformation to apply to all shapes delivered (in micrometer units)

See also global_dtrans=.

This method has been introduced in version 0.27.

Python specific notes:
The object exposes a readable attribute 'global_dtrans'. This is the getter.

global_dtrans=

Signature: void **global_dtrans=** (const DCplxTrans t)

Description: Sets the global transformation to apply to all shapes delivered (transformation in micrometer units)

The global transformation will be applied to all shapes delivered by biasing the "trans" attribute. The search regions apply to the coordinate space after global transformation.

This method has been introduced in version 0.27.

Python specific notes:

The object exposes a writable attribute 'global_dtrans'. This is the setter.

global_trans

Signature: *[const]* ICplxTrans **global_trans**

Description: Gets the global transformation to apply to all shapes delivered

See also global_trans=.

This method has been introduced in version 0.27.

Python specific notes:
The object exposes a readable attribute 'global_trans'. This is the getter.

global_trans=

Signature: void **global_trans=** (const ICplxTrans t)

Description: Sets the global transformation to apply to all shapes delivered

The global transformation will be applied to all shapes delivered by biasing the "trans" attribute. The search regions apply to the coordinate space after global transformation.

This method has been introduced in version 0.27.

Python specific notes:
The object exposes a writable attribute 'global_trans'. This is the setter.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

itrans

Signature: *[const]* ICplxTrans **itrans**

Description: Gets the current transformation by which the shapes must be transformed into the initial cell

Use of this method is deprecated. Use trans instead

The shapes delivered are not transformed. Instead, this transformation must be applied to get the shape in the coordinate system of the top cell.

Starting with version 0.25, this transformation is a int-to-int transformation the 'itrans' method which was providing this transformation before is deprecated.

layer

Signature: *[const]* unsigned int **layer**

Description: Returns the layer index where the current shape is coming from.

This method has been introduced in version 0.23.

layout

Signature: *[const]* const Layout ptr **layout**

Description: Gets the layout this iterator is connected to

This method has been introduced in version 0.23.

map_properties

Signature: void **map_properties** (map<variant,variant> key_map)

Description: Maps properties by name key.

Calling this method will reduce the properties to values with name keys from the 'keys' hash and renames the properties. Property values with keys not listed in the key map will be removed. As a side effect, this method enables properties. As with enable_properties or remove_properties, this

filter has an effect on the value returned by prop_id, not on the properties ID attached to the shape directly.

Note that property filters/mappers are additive and act in addition (after) the currently installed filter.

This feature has been introduced in version 0.28.4.

max_depth

Signature: *[const]* int **max_depth**

Description: Gets the maximum hierarchy depth

See max_depth= for a description of that attribute.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a readable attribute 'max_depth'. This is the getter.

max_depth=

Signature: void **max_depth=** (int depth)

Description: Specifies the maximum hierarchy depth to look into

A depth of 0 instructs the iterator to deliver only shapes from the initial cell. The depth must be specified before the shapes are being retrieved. Setting the depth resets the iterator.

Python specific notes:
The object exposes a writable attribute 'max_depth'. This is the setter.

min_depth

Signature: *[const]* int **min_depth**

Description: Gets the minimum hierarchy depth

See min_depth= for a description of that attribute.

This method has been introduced in version 0.27.

Python specific notes:
The object exposes a readable attribute 'min_depth'. This is the getter.

min_depth=

Signature: void **min_depth=** (int depth)

Description: Specifies the minimum hierarchy depth to look into

A depth of 0 instructs the iterator to deliver shapes from the top level. 1 instructs to deliver shapes from the first child level. The minimum depth must be specified before the shapes are being retrieved.

This method has been introduced in version 0.27.

Python specific notes:
The object exposes a writable attribute 'min_depth'. This is the setter.

new

(1) Signature: *[static]* new RecursiveShapeIterator ptr **new** (const Layout layout, const Cell cell, unsigned int layer)

Description: Creates a recursive, single-layer shape iterator.

layout:	The layout which shall be iterated
cell:	The initial cell which shall be iterated (including its children)
layer:	The layer (index) from which the shapes are taken

This constructor creates a new recursive shape iterator which delivers the shapes of the given cell plus its children from the layer given by the layer index in the "layer" parameter.

This constructor has been introduced in version 0.23.

Python specific notes:

This method is the default initializer of the object.

(2) Signature: *[static]* new RecursiveShapeIterator ptr **new** (const Layout layout, const Cell cell, unsigned int[] layers)

Description: Creates a recursive, multi-layer shape iterator.

layout:	The layout which shall be iterated
cell:	The initial cell which shall be iterated (including its children)
layers:	The layer indexes from which the shapes are taken

This constructor creates a new recursive shape iterator which delivers the shapes of the given cell plus its children from the layers given by the layer indexes in the "layers" parameter. While iterating use the layer method to retrieve the layer of the current shape.

This constructor has been introduced in version 0.23.

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new RecursiveShapeIterator ptr **new** (const Layout layout, const Cell cell, unsigned int layer, const Box box, bool overlapping = false)

Description: Creates a recursive, single-layer shape iterator with a region.

layout:	The layout which shall be iterated
cell:	The initial cell which shall be iterated (including its children)
layer:	The layer (index) from which the shapes are taken
box:	The search region
overlapping:	If set to true, shapes overlapping the search region are reported, otherwise touching is sufficient

This constructor creates a new recursive shape iterator which delivers the shapes of the given cell plus its children from the layer given by the layer index in the "layer" parameter.

The search is confined to the region given by the "box" parameter. If "overlapping" is true, shapes whose bounding box is overlapping the search region are reported. If "overlapping" is false, shapes whose bounding box touches the search region are reported.

This constructor has been introduced in version 0.23. The 'overlapping' parameter has been made optional in version 0.27.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new RecursiveShapeIterator ptr **new** (const Layout layout, const Cell cell, unsigned int layer, const Region region, bool overlapping = false)

Description: Creates a recursive, single-layer shape iterator with a region.

layout:	The layout which shall be iterated
cell:	The initial cell which shall be iterated (including its children)
layer:	The layer (index) from which the shapes are taken
region:	The search region
overlapping:	If set to true, shapes overlapping the search region are reported, otherwise touching is sufficient

This constructor creates a new recursive shape iterator which delivers the shapes of the given cell plus its children from the layer given by the layer index in the "layer" parameter.

The search is confined to the region given by the "region" parameter. The region needs to be a rectilinear region. If "overlapping" is true, shapes whose bounding box is overlapping the search

region are reported. If "overlapping" is false, shapes whose bounding box touches the search region are reported.

This constructor has been introduced in version 0.25. The 'overlapping' parameter has been made optional in version 0.27.

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new RecursiveShapeIterator ptr **new** (const Layout layout, const Cell cell, unsigned int[] layers, const Box box, bool overlapping = false)

Description: Creates a recursive, multi-layer shape iterator with a region.

layout:	The layout which shall be iterated
cell:	The initial cell which shall be iterated (including its children)
layers:	The layer indexes from which the shapes are taken
box:	The search region
overlapping:	If set to true, shapes overlapping the search region are reported, otherwise touching is sufficient

This constructor creates a new recursive shape iterator which delivers the shapes of the given cell plus its children from the layers given by the layer indexes in the "layers" parameter. While iterating use the layer method to retrieve the layer of the current shape.

The search is confined to the region given by the "box" parameter. If "overlapping" is true, shapes whose bounding box is overlapping the search region are reported. If "overlapping" is false, shapes whose bounding box touches the search region are reported.

This constructor has been introduced in version 0.23. The 'overlapping' parameter has been made optional in version 0.27.

Python specific notes:
This method is the default initializer of the object.

(6) Signature: *[static]* new RecursiveShapeIterator ptr **new** (const Layout layout, const Cell cell, unsigned int[] layers, const Region region, bool overlapping = false)

Description: Creates a recursive, multi-layer shape iterator with a region.

layout:	The layout which shall be iterated
cell:	The initial cell which shall be iterated (including its children)
layers:	The layer indexes from which the shapes are taken
region:	The search region
overlapping:	If set to true, shapes overlapping the search region are reported, otherwise touching is sufficient

This constructor creates a new recursive shape iterator which delivers the shapes of the given cell plus its children from the layers given by the layer indexes in the "layers" parameter. While iterating use the layer method to retrieve the layer of the current shape.

The search is confined to the region given by the "region" parameter. The region needs to be a rectilinear region. If "overlapping" is true, shapes whose bounding box is overlapping the search region are reported. If "overlapping" is false, shapes whose bounding box touches the search region are reported.

This constructor has been introduced in version 0.23. The 'overlapping' parameter has been made optional in version 0.27.

Python specific notes:
This method is the default initializer of the object.

next

Signature: void **next**

Description: Increments the iterator

This moves the iterator to the next shape inside the search scope.

overlapping=

Signature: void **overlapping=** (bool flag)

Description: Sets a flag indicating whether overlapping shapes are selected when a region is used

If this flag is false, shapes touching the search region are returned.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'overlapping'. This is the setter.

overlapping?

Signature: *[const]* bool **overlapping?**

Description: Gets a flag indicating whether overlapping shapes are selected when a region is used

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a readable attribute 'overlapping'. This is the getter.

path

Signature: *[const]* InstElement[] **path**

Description: Gets the instantiation path of the shape addressed currently

This attribute is a sequence of InstElement objects describing the cell instance path from the initial cell to the current cell containing the current shape.

This method has been introduced in version 0.25.

prop_id

Signature: *[const]* unsigned long **prop_id**

Description: Gets the effective properties ID

The shape iterator supports property filtering and translation. This method will deliver the effective property ID after translation. The original property ID can be obtained from 'shape.prop_id' and is not changed by installing filters or mappers.

prop_id is evaluated by Region objects for example, when they are created from a shape iterator.

See enable_properties, filter_properties, remove_properties and map_properties for details on this feature.

This attribute has been introduced in version 0.28.4.

region

Signature: *[const]* Box **region**

Description: Gets the basic region that this iterator is using

The basic region is the overall box the region iterator iterates over. There may be an additional complex region that confines the region iterator. See complex_region for this attribute.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a readable attribute 'region'. This is the getter.

region=

(1) Signature: void **region=** (const Box box_region)

Description: Sets the rectangular region that this iterator is iterating over

See region for a description of this attribute. Setting a simple region will reset the complex region to a rectangle and reset the iterator to the beginning of the sequence. This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'region'. This is the setter.

(2) Signature: void **region=** (const Region complex_region)

Description: Sets the complex region that this iterator is using

See complex_region for a description of this attribute. Setting the complex region will reset the basic region (see region) to the bounding box of the complex region and reset the iterator to the beginning of the sequence.

This method overload has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'region'. This is the setter.

remove_properties

Signature: void **remove_properties**

Description: Removes properties for the given container.

This will remove all properties and prop_id will deliver 0 always (no properties attached). Alternatively you can apply filter_properties or map_properties to enable properties with a specific name key.

Note that property filters/mappers are additive and act in addition (after) the currently installed filter. So effectively after 'remove_properties' you cannot get them back.

This feature has been introduced in version 0.28.4.

reset

Signature: void **reset**

Description: Resets the iterator to the initial state

This method has been introduced in version 0.23.

reset_selection

Signature: void **reset_selection**

Description: Resets the selection to the default state

In the initial state, the top cell and its children are selected. Child cells can be switched on and off together with their sub-hierarchy using select_cells and unselect_cells.

This method will also reset the iterator.

This method has been introduced in version 0.23.

select_all_cells

Signature: void **select_all_cells**

Description: Selects all cells.

This method will set the "selected" mark on all cells. The effect is that subsequent calls of unselect_cells will unselect only the specified cells, not their children, because they are still unselected.

This method will also reset the iterator.

This method has been introduced in version 0.23.

select_cells

(1) Signature: void **select_cells** (unsigned int[] cells)

Description: Unselects the given cells.

This method will sets the "selected" mark on the given cells. That means that these cells or their child cells are visited, unless they are marked as "unselected" again with the unselect_cells method.

The cells are given as a list of cell indexes.

This method will also reset the iterator.

This method has been introduced in version 0.23.

(2) Signature: void **select_cells** (string cells)

Description: Unselects the given cells.

This method will sets the "selected" mark on the given cells. That means that these cells or their child cells are visited, unless they are marked as "unselected" again with the unselect_cells method.

The cells are given as a glob pattern. A glob pattern follows the syntax of file names on the shell (i.e. "A*" are all cells starting with a letter "A").

This method will also reset the iterator.

This method has been introduced in version 0.23.

shape

Signature: *[const]* Shape **shape**

Description: Gets the current shape

Returns the shape currently referred to by the recursive iterator. This shape is not transformed yet and is located in the current cell.

shape_flags

Signature: *[const]* unsigned int **shape_flags**

Description: Gets the shape selection flags

See shape_flags= for a description of that property.

This getter has been introduced in version 0.28.

Python specific notes:
The object exposes a readable attribute 'shape_flags'. This is the getter.

shape_flags=

Signature: void **shape_flags=** (unsigned int flags)

Description: Specifies the shape selection flags

The flags are the same then being defined in Shapes (the default is RBA::Shapes::SAll). The flags must be specified before the shapes are being retrieved. Settings the shapes flags will reset the iterator.

Python specific notes:
The object exposes a writable attribute 'shape_flags'. This is the setter.

top_cell

Signature: *[const]* const Cell ptr **top_cell**

Description: Gets the top cell this iterator is connected to

This method has been introduced in version 0.23.

trans

Signature: *[const]* ICplxTrans **trans**

Description: Gets the current transformation by which the shapes must be transformed into the initial cell

The shapes delivered are not transformed. Instead, this transformation must be applied to get the shape in the coordinate system of the top cell.

Starting with version 0.25, this transformation is a int-to-int transformation the 'itrans' method which was providing this transformation before is deprecated.

unselect_all_cells

Signature: void **unselect_all_cells**

Description: Unselects all cells.

This method will set the "unselected" mark on all cells. The effect is that subsequent calls of select_cells will select only the specified cells, not their children, because they are still unselected.

This method will also reset the iterator.

This method has been introduced in version 0.23.

unselect_cells

(1) Signature: void **unselect_cells** (unsigned int[] cells)

Description: Unselects the given cells.

This method will sets the "unselected" mark on the given cells. That means that these cells or their child cells will not be visited, unless they are marked as "selected" again with the select_cells method.

The cells are given as a list of cell indexes.

This method will also reset the iterator.

This method has been introduced in version 0.23.

(2) Signature: void **unselect_cells** (string cells)

Description: Unselects the given cells.

This method will sets the "unselected" mark on the given cells. That means that these cells or their child cells will not be visited, unless they are marked as "selected" again with the select_cells method.

The cells are given as a glob pattern. A glob pattern follows the syntax of file names on the shell (i.e. "A*" are all cells starting with a letter "A").

This method will also reset the iterator.

This method has been introduced in version 0.23.

4.83. API reference - Class PolygonFilter

Notation used in Ruby API documentation

Module: db

Description: A generic polygon filter adaptor

Polygon filters are an efficient way to filter polygons from a Region. To apply a filter, derive your own filter class and pass an instance to the Region#filter or Region#filtered method.

Conceptually, these methods take each polygon from the region and present it to the filter's 'selected' method. Based on the result of this evaluation, the polygon is kept or discarded.

The magic happens when deep mode regions are involved. In that case, the filter will use as few calls as possible and exploit the hierarchical compression if possible. It needs to know however, how the filter behaves. You need to configure the filter by calling is_isotropic, is_scale_invariant or is_isotropic_and_scale_invariant before using the filter.

You can skip this step, but the filter algorithm will assume the worst case then. This usually leads to cell variant formation which is not always desired and blows up the hierarchy.

Here is some example that filters triangles:

```
class TriangleFilter < RBA::PolygonFilter

  # Constructor
  def initialize
    self.is_isotropic_and_scale_invariant   # the triangle nature is not dependent on the scale or
 orientation
  end

  # Select only triangles
  def selected(polygon)
    return polygon.holes == 0 && polygon.num_points == 3
  end

end

region = ... # some Region
triangles_only = region.filtered(TriangleFilter::new)
```

This class has been introduced in version 0.29.

Public constructors

new PolygonFilter ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference
	void	**_manage**	Marks the object as managed by the script side.

	void	_unmanage		Marks the object as no longer owned by the script side.
	void	is_isotropic		Indicates that the filter has isotropic properties
	void	is_isotropic_and_scale_invariant		Indicates that the filter is isotropic and scale invariant
	void	is_scale_invariant		Indicates that the filter is scale invariant
	void	requires_raw_input=	(bool flag)	Sets a value indicating whether the filter needs raw (unmerged) input
[const]	bool	requires_raw_input?		Gets a value indicating whether the filter needs raw (unmerged) input
[virtual,const]	bool	selected	(const Polygon polygon)	Selects a polygon
	void	wants_variants=	(bool flag)	Sets a value indicating whether the filter prefers cell variants
[const]	bool	wants_variants?		Gets a value indicating whether the filter prefers cell variants

Deprecated methods (protected, public, static, non-static and constructors)

	void	create	Use of this method is deprecated. Use _create instead
	void	destroy	Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	is_const_object?	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_isotropic

Signature: void **is_isotropic**

Description: Indicates that the filter has isotropic properties

Call this method before using the filter to indicate that the selection is independent of the orientation of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

Examples for isotropic (polygon) filters are area or perimeter filters. The area or perimeter of a polygon depends on the scale, but not on the orientation of the polygon.

is_isotropic_and_scale_invariant

Signature: void **is_isotropic_and_scale_invariant**

Description: Indicates that the filter is isotropic and scale invariant

Call this method before using the filter to indicate that the selection is independent of the scale and orientation of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

An example for such a (polygon) filter is the square selector. Whether a polygon is a square or not does not depend on the polygon's orientation nor scale.

is_scale_invariant

Signature: void **is_scale_invariant**

Description: Indicates that the filter is scale invariant

Call this method before using the filter to indicate that the selection is independent of the scale of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

An example for a scale invariant (polygon) filter is the bounding box aspect ratio (height/width) filter. The definition of heigh and width depends on the orientation, but the ratio is independent on scale.

new

Signature: *[static]* new PolygonFilter ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

requires_raw_input=

Signature: void **requires_raw_input=** (bool flag)

Description: Sets a value indicating whether the filter needs raw (unmerged) input

This flag must be set before using this filter. It tells the filter implementation whether the filter wants to have raw input (unmerged). The default value is 'false', meaning that the filter will receive merged polygons ('merged semantics').

Setting this value to false potentially saves some CPU time needed for merging the polygons. Also, raw input means that strange shapes such as dot-like edges, self-overlapping polygons, empty or degenerated polygons are preserved.

Python specific notes:
The object exposes a writable attribute 'requires_raw_input'. This is the setter.

requires_raw_input?

Signature: *[const]* bool **requires_raw_input?**

Description: Gets a value indicating whether the filter needs raw (unmerged) input

See requires_raw_input= for details.

Python specific notes:
The object exposes a readable attribute 'requires_raw_input'. This is the getter.

selected

Signature: *[virtual,const]* bool **selected** (const Polygon polygon)

Description: Selects a polygon

This method is the actual payload. It needs to be reimplemented in a derived class. It needs to analyze the polygon and return 'true' if it should be kept and 'false' if it should be discarded.

wants_variants=

Signature: void **wants_variants=** (bool flag)

Description: Sets a value indicating whether the filter prefers cell variants

This flag must be set before using this filter for hierarchical applications (deep mode). It tells the filter implementation whether cell variants should be created (true, the default) or shape propagation will be applied (false).

This decision needs to be made, if the filter indicates that it will deliver different results for scaled or rotated versions of the shape (see is_isotropic and the other hints). If a cell is present with different qualities - as seen from the top cell - the respective instances need to be differentiated. Cell variant formation is one way, shape propagation the other way. Typically, cell variant formation is less expensive, but the hierarchy will be modified.

Python specific notes:
The object exposes a writable attribute 'wants_variants'. This is the setter.

wants_variants?

Signature: *[const]* bool **wants_variants?**

Description: Gets a value indicating whether the filter prefers cell variants

See wants_variants= for details.

Python specific notes:
The object exposes a readable attribute 'wants_variants'. This is the getter.

4.84. API reference - Class PolygonOperator

Notation used in Ruby API documentation

Module: db

Description: A generic polygon operator

Polygon processors are an efficient way to process polygons from a Region. To apply a processor, derive your own operator class and pass an instance to the Region#process or Region#processed method.

Conceptually, these methods take each polygon from the region and present it to the operators' 'process' method. The result of this call is a list of zero to many output polygons derived from the input polygon. The output region is the sum over all these individual results.

The magic happens when deep mode regions are involved. In that case, the processor will use as few calls as possible and exploit the hierarchical compression if possible. It needs to know however, how the operator behaves. You need to configure the operator by calling is_isotropic, is_scale_invariant or is_isotropic_and_scale_invariant before using it.

You can skip this step, but the processor algorithm will assume the worst case then. This usually leads to cell variant formation which is not always desired and blows up the hierarchy.

Here is some example that shrinks every polygon to half of the size but does not change the position. In this example the 'position' is defined by the center of the bounding box:

```
class ShrinkToHalf < RBA::PolygonOperator

  # Constructor
  def initialize
    self.is_isotropic_and_scale_invariant   # scale or orientation do not matter
  end

  # Shrink to half size
  def process(polygon)
    shift = polygon.bbox.center - RBA::Point::new   # shift vector
    return [ (polygon.moved(-shift) * 0.5).moved(shift) ]
  end

end

region = ... # some Region
shrinked_to_half = region.processed(ShrinkToHalf::new)
```

This class has been introduced in version 0.29.

Public constructors

new PolygonOperator ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference
	void	**_manage**	Marks the object as managed by the script side.

	void	_unmanage		Marks the object as no longer owned by the script side.
	void	is_isotropic		Indicates that the filter has isotropic properties
	void	is_isotropic_and_scale_invariant		Indicates that the filter is isotropic and scale invariant
	void	is_scale_invariant		Indicates that the filter is scale invariant
[virtual,const]	Polygon[]	process	(const Polygon shape)	Processes a shape
	void	requires_raw_input=	(bool flag)	Sets a value indicating whether the processor needs raw (unmerged) input
[const]	bool	requires_raw_input?		Gets a value indicating whether the processor needs raw (unmerged) input
	void	result_is_merged=	(bool flag)	Sets a value indicating whether the processor delivers merged output
[const]	bool	result_is_merged?		Gets a value indicating whether the processor delivers merged output
	void	result_must_not_be_merge	(bool flag)	Sets a value indicating whether the processor's output must not be merged
[const]	bool	result_must_not_be_merged?		Gets a value indicating whether the processor's output must not be merged
	void	wants_variants=	(bool flag)	Sets a value indicating whether the filter prefers cell variants
[const]	bool	wants_variants?		Gets a value indicating whether the filter prefers cell variants

Deprecated methods (protected, public, static, non-static and constructors)

	void	create	Use of this method is deprecated. Use _create instead
	void	destroy	Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	is_const_object?	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void _**create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_isotropic

Signature: void **is_isotropic**

Description: Indicates that the filter has isotropic properties

Call this method before using the filter to indicate that the selection is independent of the orientation of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

Examples for isotropic (polygon) processors are size or shrink operators. Size or shrink is not dependent on orientation unless size or shrink needs to be different in x and y direction.

is_isotropic_and_scale_invariant

Signature: void **is_isotropic_and_scale_invariant**

Description: Indicates that the filter is isotropic and scale invariant

Call this method before using the filter to indicate that the selection is independent of the scale and orientation of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

An example for such a (polygon) processor is the convex decomposition operator. The decomposition of a polygon into convex parts is an operation that is not depending on scale nor orientation.

is_scale_invariant

Signature: void **is_scale_invariant**

Description: Indicates that the filter is scale invariant

Call this method before using the filter to indicate that the selection is independent of the scale of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

An example for a scale invariant (polygon) processor is the rotation operator. Rotation is not depending on scale, but on the original orientation as mirrored versions need to be rotated differently.

new

Signature: *[static]* new PolygonOperator ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

process

Signature: *[virtual,const]* Polygon[] **process** (const Polygon shape)

Description: Processes a shape

	This method is the actual payload. It needs to be reimplemented in a derived class. If needs to process the input shape and deliver a list of output shapes. The output list may be empty to entirely discard the input shape. It may also contain more than a single shape. In that case, the number of total shapes may grow during application of the processor.
requires_raw_input=	**Signature**: void **requires_raw_input=** (bool flag) **Description**: Sets a value indicating whether the processor needs raw (unmerged) input This flag must be set before using this processor. It tells the processor implementation whether the processor wants to have raw input (unmerged). The default value is 'false', meaning that the processor will receive merged polygons ('merged semantics'). Setting this value to false potentially saves some CPU time needed for merging the polygons. Also, raw input means that strange shapes such as dot-like edges, self-overlapping polygons, empty or degenerated polygons are preserved. **Python specific notes:** The object exposes a writable attribute 'requires_raw_input'. This is the setter.
requires_raw_input?	**Signature**: *[const]* bool **requires_raw_input?** **Description**: Gets a value indicating whether the processor needs raw (unmerged) input See requires_raw_input= for details. **Python specific notes:** The object exposes a readable attribute 'requires_raw_input'. This is the getter.
result_is_merged=	**Signature**: void **result_is_merged=** (bool flag) **Description**: Sets a value indicating whether the processor delivers merged output This flag must be set before using this processor. If the processor maintains the merged condition by design (output is merged if input is), it is a good idea to set this predicate to 'true'. This will avoid additional merge steps when the resulting collection is used in further operations that need merged input . **Python specific notes:** The object exposes a writable attribute 'result_is_merged'. This is the setter.
result_is_merged?	**Signature**: *[const]* bool **result_is_merged?** **Description**: Gets a value indicating whether the processor delivers merged output See result_is_merged= for details. **Python specific notes:** The object exposes a readable attribute 'result_is_merged'. This is the getter.
result_must_not_be_merged=	**Signature**: void **result_must_not_be_merged=** (bool flag) **Description**: Sets a value indicating whether the processor's output must not be merged This flag must be set before using this processor. The processor can set this flag if it wants to deliver shapes that must not be merged - e.g. point-like edges or strange or degenerated polygons. . **Python specific notes:** The object exposes a writable attribute 'result_must_not_be_merged'. This is the setter.
result_must_not_be_merged	**Signature**: *[const]* bool **result_must_not_be_merged?** **Description**: Gets a value indicating whether the processor's output must not be merged See result_must_not_be_merged= for details. **Python specific notes:**

	The object exposes a readable attribute 'result_must_not_be_merged'. This is the getter.
wants_variants=	**Signature**: void **wants_variants=** (bool flag) **Description**: Sets a value indicating whether the filter prefers cell variants This flag must be set before using this filter for hierarchical applications (deep mode). It tells the filter implementation whether cell variants should be created (true, the default) or shape propagation will be applied (false). This decision needs to be made, if the filter indicates that it will deliver different results for scaled or rotated versions of the shape (see is_isotropic and the other hints). If a cell is present with different qualities - as seen from the top cell - the respective instances need to be differentiated. Cell variant formation is one way, shape propagation the other way. Typically, cell variant formation is less expensive, but the hierarchy will be modified. **Python specific notes:** The object exposes a writable attribute 'wants_variants'. This is the setter.
wants_variants?	**Signature**: *[const]* bool **wants_variants?** **Description**: Gets a value indicating whether the filter prefers cell variants See wants_variants= for details. **Python specific notes:** The object exposes a readable attribute 'wants_variants'. This is the getter.

4.85. API reference - Class PolygonToEdgeOperator

Notation used in Ruby API documentation

Module: db

Description: A generic polygon-to-edge operator

Polygon processors are an efficient way to process polygons from a Region. To apply a processor, derive your own operator class and pass an instance to the Region#processed method.

Conceptually, these methods take each polygon from the region and present it to the operator's 'process' method. The result of this call is a list of zero to many output edges derived from the input polygon. The output edge collection is the sum over all these individual results.

The magic happens when deep mode regions are involved. In that case, the processor will use as few calls as possible and exploit the hierarchical compression if possible. It needs to know however, how the operator behaves. You need to configure the operator by calling is_isotropic, is_scale_invariant or is_isotropic_and_scale_invariant before using it.

You can skip this step, but the processor algorithm will assume the worst case then. This usually leads to cell variant formation which is not always desired and blows up the hierarchy.

For a basic example see the PolygonOperator class, with the exception that this incarnation has to deliver edges.

This class has been introduced in version 0.29.

Public constructors

new PolygonToEdgeOperator ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**is_isotropic**		Indicates that the filter has isotropic properties
	void	**is_isotropic_and_scale_invariant**		Indicates that the filter is isotropic and scale invariant
	void	**is_scale_invariant**		Indicates that the filter is scale invariant
[virtual,const]	Edge[]	**process**	(const Polygon shape)	Processes a shape
	void	**requires_raw_input=**	(bool flag)	Sets a value indicating whether the processor needs raw (unmerged) input

[const]	bool	**requires_raw_input?**		Gets a value indicating whether the processor needs raw (unmerged) input
	void	**result_is_merged=**	(bool flag)	Sets a value indicating whether the processor delivers merged output
[const]	bool	**result_is_merged?**		Gets a value indicating whether the processor delivers merged output
	void	**result_must_not_be_merge**	(bool flag)	Sets a value indicating whether the processor's output must not be merged
[const]	bool	**result_must_not_be_merged?**		Gets a value indicating whether the processor's output must not be merged
	void	**wants_variants=**	(bool flag)	Sets a value indicating whether the filter prefers cell variants
[const]	bool	**wants_variants?**		Gets a value indicating whether the filter prefers cell variants

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_isotropic

Signature: void **is_isotropic**

Description: Indicates that the filter has isotropic properties

Call this method before using the filter to indicate that the selection is independent of the orientation of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

Examples for isotropic (polygon) processors are size or shrink operators. Size or shrink is not dependent on orientation unless size or shrink needs to be different in x and y direction.

is_isotropic_and_scale_invariant

Signature: void **is_isotropic_and_scale_invariant**

Description: Indicates that the filter is isotropic and scale invariant

Call this method before using the filter to indicate that the selection is independent of the scale and orientation of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

An example for such a (polygon) processor is the convex decomposition operator. The decomposition of a polygon into convex parts is an operation that is not depending on scale nor orientation.

is_scale_invariant

Signature: void **is_scale_invariant**

Description: Indicates that the filter is scale invariant

Call this method before using the filter to indicate that the selection is independent of the scale of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

An example for a scale invariant (polygon) processor is the rotation operator. Rotation is not depending on scale, but on the original orientation as mirrored versions need to be rotated differently.

new

Signature: *[static]* new PolygonToEdgeOperator ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

process

Signature: *[virtual,const]* Edge[] **process** (const Polygon shape)

Description: Processes a shape

This method is the actual payload. It needs to be reimplemented in a derived class. If needs to process the input shape and deliver a list of output shapes. The output list may be empty to entirely discard the input shape. It may also contain more than a single shape. In that case, the number of total shapes may grow during application of the processor.

requires_raw_input=

Signature: void **requires_raw_input=** (bool flag)

Description: Sets a value indicating whether the processor needs raw (unmerged) input

This flag must be set before using this processor. It tells the processor implementation whether the processor wants to have raw input (unmerged). The default value is 'false', meaning that the processor will receive merged polygons ('merged semantics').

Setting this value to false potentially saves some CPU time needed for merging the polygons. Also, raw input means that strange shapes such as dot-like edges, self-overlapping polygons, empty or degenerated polygons are preserved.

Python specific notes:
The object exposes a writable attribute 'requires_raw_input'. This is the setter.

requires_raw_input?

Signature: *[const]* bool **requires_raw_input?**

Description: Gets a value indicating whether the processor needs raw (unmerged) input

See requires_raw_input= for details.

Python specific notes:
The object exposes a readable attribute 'requires_raw_input'. This is the getter.

result_is_merged=

Signature: void **result_is_merged=** (bool flag)

Description: Sets a value indicating whether the processor delivers merged output

This flag must be set before using this processor. If the processor maintains the merged condition by design (output is merged if input is), it is a good idea to set this predicate to 'true'. This will avoid additional merge steps when the resulting collection is used in further operations that need merged input .

Python specific notes:
The object exposes a writable attribute 'result_is_merged'. This is the setter.

result_is_merged?

Signature: *[const]* bool **result_is_merged?**

Description: Gets a value indicating whether the processor delivers merged output

See result_is_merged= for details.

Python specific notes:
The object exposes a readable attribute 'result_is_merged'. This is the getter.

result_must_not_be_merged=

Signature: void **result_must_not_be_merged=** (bool flag)

Description: Sets a value indicating whether the processor's output must not be merged

This flag must be set before using this processor. The processor can set this flag if it wants to deliver shapes that must not be merged - e.g. point-like edges or strange or degenerated polygons. .

Python specific notes:
The object exposes a writable attribute 'result_must_not_be_merged'. This is the setter.

result_must_not_be_merged

Signature: *[const]* bool **result_must_not_be_merged?**

Description: Gets a value indicating whether the processor's output must not be merged

See result_must_not_be_merged= for details.

Python specific notes:
The object exposes a readable attribute 'result_must_not_be_merged'. This is the getter.

wants_variants=

Signature: void **wants_variants=** (bool flag)

Description: Sets a value indicating whether the filter prefers cell variants

This flag must be set before using this filter for hierarchical applications (deep mode). It tells the filter implementation whether cell variants should be created (true, the default) or shape propagation will be applied (false).

This decision needs to be made, if the filter indicates that it will deliver different results for scaled or rotated versions of the shape (see is_isotropic and the other hints). If a cell is present with different qualities - as seen from the top cell - the respective instances need to be differentiated. Cell variant formation is one way, shape propagation the other way. Typically, cell variant formation is less expensive, but the hierarchy will be modified.

Python specific notes:
The object exposes a writable attribute 'wants_variants'. This is the setter.

wants_variants?

Signature: *[const]* bool **wants_variants?**

Description: Gets a value indicating whether the filter prefers cell variants

See wants_variants= for details.

Python specific notes:
The object exposes a readable attribute 'wants_variants'. This is the getter.

4.86. API reference - Class PolygonToEdgePairOperator

Notation used in Ruby API documentation

Module: db

Description: A generic polygon-to-edge-pair operator

Polygon processors are an efficient way to process polygons from a Region. To apply a processor, derive your own operator class and pass an instance to the Region#processed method.

Conceptually, these methods take each polygon from the region and present it to the operator's 'process' method. The result of this call is a list of zero to many output edge pairs derived from the input polygon. The output edge pair collection is the sum over all these individual results.

The magic happens when deep mode regions are involved. In that case, the processor will use as few calls as possible and exploit the hierarchical compression if possible. It needs to know however, how the operator behaves. You need to configure the operator by calling is_isotropic, is_scale_invariant or is_isotropic_and_scale_invariant before using it.

You can skip this step, but the processor algorithm will assume the worst case then. This usually leads to cell variant formation which is not always desired and blows up the hierarchy.

For a basic example see the PolygonOperator class, with the exception that this incarnation has to deliver edge pairs.

This class has been introduced in version 0.29.

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_isotropic

Signature: void **is_isotropic**

Description: Indicates that the filter has isotropic properties

Call this method before using the filter to indicate that the selection is independent of the orientation of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

Examples for isotropic (polygon) processors are size or shrink operators. Size or shrink is not dependent on orientation unless size or shrink needs to be different in x and y direction.

is_isotropic_and_scale_invariant

Signature: void **is_isotropic_and_scale_invariant**

Description: Indicates that the filter is isotropic and scale invariant

Call this method before using the filter to indicate that the selection is independent of the scale and orientation of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

An example for such a (polygon) processor is the convex decomposition operator. The decomposition of a polygon into convex parts is an operation that is not depending on scale nor orientation.

is_scale_invariant

Signature: void **is_scale_invariant**

Description: Indicates that the filter is scale invariant

Call this method before using the filter to indicate that the selection is independent of the scale of the shape. This helps the filter algorithm optimizing the filter run, specifically in hierarchical mode.

An example for a scale invariant (polygon) processor is the rotation operator. Rotation is not depending on scale, but on the original orientation as mirrored versions need to be rotated differently.

new

Signature: *[static]* new PolygonToEdgePairOperator ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

process

Signature: *[virtual,const]* EdgePair[] **process** (const Polygon shape)

Description: Processes a shape

This method is the actual payload. It needs to be reimplemented in a derived class. If needs to process the input shape and deliver a list of output shapes. The output list may be empty to entirely discard the input shape. It may also contain more than a single shape. In that case, the number of total shapes may grow during application of the processor.

requires_raw_input=

Signature: void **requires_raw_input=** (bool flag)

Description: Sets a value indicating whether the processor needs raw (unmerged) input

This flag must be set before using this processor. It tells the processor implementation whether the processor wants to have raw input (unmerged). The default value is 'false', meaning that the processor will receive merged polygons ('merged semantics').

Setting this value to false potentially saves some CPU time needed for merging the polygons. Also, raw input means that strange shapes such as dot-like edges, self-overlapping polygons, empty or degenerated polygons are preserved.

Python specific notes:
The object exposes a writable attribute 'requires_raw_input'. This is the setter.

requires_raw_input?

Signature: *[const]* bool **requires_raw_input?**

Description: Gets a value indicating whether the processor needs raw (unmerged) input

See requires_raw_input= for details.

Python specific notes:
The object exposes a readable attribute 'requires_raw_input'. This is the getter.

result_is_merged=

Signature: void **result_is_merged=** (bool flag)

Description: Sets a value indicating whether the processor delivers merged output

This flag must be set before using this processor. If the processor maintains the merged condition by design (output is merged if input is), it is a good idea to set this predicate to 'true'. This will avoid additional merge steps when the resulting collection is used in further operations that need merged input .

Python specific notes:
The object exposes a writable attribute 'result_is_merged'. This is the setter.

result_is_merged?

Signature: *[const]* bool **result_is_merged?**

Description: Gets a value indicating whether the processor delivers merged output

See result_is_merged= for details.

Python specific notes:
The object exposes a readable attribute 'result_is_merged'. This is the getter.

result_must_not_be_merged=

Signature: void **result_must_not_be_merged=** (bool flag)

Description: Sets a value indicating whether the processor's output must not be merged

This flag must be set before using this processor. The processor can set this flag if it wants to deliver shapes that must not be merged - e.g. point-like edges or strange or degenerated polygons. .

Python specific notes:
The object exposes a writable attribute 'result_must_not_be_merged'. This is the setter.

result_must_not_be_merged

Signature: *[const]* bool **result_must_not_be_merged?**

Description: Gets a value indicating whether the processor's output must not be merged

See result_must_not_be_merged= for details.

Python specific notes:
The object exposes a readable attribute 'result_must_not_be_merged'. This is the getter.

wants_variants=

Signature: void **wants_variants=** (bool flag)

Description: Sets a value indicating whether the filter prefers cell variants

This flag must be set before using this filter for hierarchical applications (deep mode). It tells the filter implementation whether cell variants should be created (true, the default) or shape propagation will be applied (false).

This decision needs to be made, if the filter indicates that it will deliver different results for scaled or rotated versions of the shape (see is_isotropic and the other hints). If a cell is present with different qualities - as seen from the top cell - the respective instances need to be differentiated. Cell variant formation is one way, shape propagation the other way. Typically, cell variant formation is less expensive, but the hierarchy will be modified.

Python specific notes:
The object exposes a writable attribute 'wants_variants'. This is the setter.

wants_variants?

Signature: *[const]* bool **wants_variants?**

Description: Gets a value indicating whether the filter prefers cell variants

See wants_variants= for details.

Python specific notes:
The object exposes a readable attribute 'wants_variants'. This is the getter.

4.87. API reference - Class Region

Notation used in Ruby API documentation

Module: db

Description: A region (a potentially complex area consisting of multiple polygons)

Class hierarchy: Region » ShapeCollection

Sub-classes: RectFilter, OppositeFilter

This class was introduced to simplify operations on polygon sets like boolean or sizing operations. Regions consist of many polygons and thus are a generalization of single polygons which describes a single coherence set of points. Regions support a variety of operations and have several states.

The region's state can be empty (does not contain anything) or box-like, i.e. the region consists of a single box. In that case, some operations can be simplified. Regions can have merged state. In merged state, regions consist of merged (non-touching, non-self overlapping) polygons. Each polygon describes one coherent area in merged state.

The preferred representation of polygons inside the region are polygons with holes.

Regions are always expressed in database units. If you want to use regions from different database unit domains, scale the regions accordingly, i.e. by using the transformed method.

Regions provide convenient operators for the boolean operations. Hence it is often no longer required to work with the EdgeProcessor class. For example:

```
r1 = RBA::Region::new(RBA::Box::new(0, 0, 100, 100))
r2 = RBA::Region::new(RBA::Box::new(20, 20, 80, 80))
# compute the XOR:
r1_xor_r2 = r1 ^ r2
```

Regions can be used in two different flavors: in raw mode or merged semantics. With merged semantics (the default), connected polygons are considered to belong together and are effectively merged. Overlapping areas are counted once in that mode. Internal edges (i.e. arising from cut lines) are not considered. In raw mode (without merged semantics), each polygon is considered as it is. Overlaps between polygons may exists and merging has to be done explicitly using the merge method. The semantics can be selected using merged_semantics=.

This class has been introduced in version 0.23.

Public constructors

new Region ptr	**new**		Default constructor
new Region ptr	**new**	(Polygon[] array)	Constructor from a polygon array
new Region ptr	**new**	(const Box box)	Box constructor
new Region ptr	**new**	(const Polygon polygon)	Polygon constructor
new Region ptr	**new**	(const SimplePolygon polygon)	Simple polygon constructor
new Region ptr	**new**	(const Path path)	Path constructor
new Region ptr	**new**	(const RecursiveShapeIterator shape_iterator)	Constructor from a hierarchical shape set
new Region ptr	**new**	(const RecursiveShapeIterator shape_iterator, const ICplxTrans trans)	Constructor from a hierarchical shape set with a transformation

new Region ptr	new	(const Shapes shapes)	Constructor from a shapes container
new Region ptr	new	(const Shapes shapes, const ICplxTrans trans)	Constructor from a shapes container with a transformation
new Region ptr	new	(const RecursiveShapeIterator shape_iterator, DeepShapeStore deep_shape_store, double area_ratio = 0, unsigned long max_vertex_count = 0)	Constructor for a deep region from a hierarchical shape set
new Region ptr	new	(const RecursiveShapeIterator shape_iterator, DeepShapeStore deep_shape_store, const ICplxTrans trans, double area_ratio = 0, unsigned long max_vertex_count = 0)	Constructor for a deep region from a hierarchical shape set
new Region ptr	new	(const RecursiveShapeIterator shape_iterator, string expr, bool as_pattern = true, int enl = 1)	Constructor from a text set
new Region ptr	new	(const RecursiveShapeIterator shape_iterator, DeepShapeStore dss, string expr, bool as_pattern = true, int enl = 1)	Constructor from a text set

Public methods

[const]	Region	&	(const Region other)	Returns the boolean AND between self and the other region
	Region	&=	(const Region other)	Performs the boolean AND between self and the other region in-place (modifying self)
[const]	Region	+	(const Region other)	Returns the combined region of self and the other region
	Region	+=	(const Region other)	Adds the polygons of the other region to self
[const]	Region	-	(const Region other)	Returns the boolean NOT between self and the other region
	Region	-=	(const Region other)	Performs the boolean NOT between self and the other region in-place (modifying self)
[const]	const Polygon ptr	[]	(unsigned long n)	Returns the nth polygon of the region
[const]	Region	^	(const Region other)	Returns the boolean XOR between self and the other region

	Region	**^=**	(const Region other)	Performs the boolean XOR between self and the other region in-place (modifying self)
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	Region	**and**	(const Region other, PropertyConstraint property_constraint = IgnoreProperties)	Returns the boolean AND between self and the other region
	Region	**and_with**	(const Region other, PropertyConstraint property_constraint = IgnoreProperties)	Performs the boolean AND between self and the other region in-place (modifying self)
[const]	Region[]	**andnot**	(const Region other, PropertyConstraint property_constraint = IgnoreProperties)	Returns the boolean AND and NOT between self and the other region
[const]	long	**area**		The area of the region
[const]	long	**area**	(const Box rect)	The area of the region (restricted to a rectangle)
	void	**assign**	(const Region other)	Assigns another object to self
[const]	unsigned int	**base_verbosity**		Gets the minimum verbosity for timing reports
	void	**base_verbosity=**	(int verbosity)	Sets the minimum verbosity for timing reports
[const]	Box	**bbox**		Return the bounding box of the region
	void	**break**	(unsigned long max_vertex_count, double max_area_ratio = 0)	Breaks the polygons of the region into smaller ones
	void	**clear**		Clears the region
	variant	**complex_op**	(CompoundRegionOperationNode ptr node,	Executes a complex operation (see CompoundRegionOperationNode for details)

			PropertyConstraint property_constraint = IgnoreProperties)	
[const]	Region	**corners**	(double angle_min = -180, double angle_max = 180, int dim = 1, bool include_min_angle = true, bool include_max_angle = true)	This method will select all corners whose attached edges satisfy the angle condition.
[const]	Edges	**corners_dots**	(double angle_start = -180, double angle_end = 180, bool include_min_angle = true, bool include_max_angle = true)	This method will select all corners whose attached edges satisfy the angle condition.
[const]	EdgePairs	**corners_edge_pairs**	(double angle_start = -180, double angle_end = 180, bool include_min_angle = true, bool include_max_angle = true)	This method will select all corners whose attached edges satisfy the angle condition.
[const]	unsigned long	**count**		Returns the (flat) number of polygons in the region
[const]	Region	**covering**	(const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Returns the polygons of this region which are completely covering polygons from the other region
[const]	unsigned long	**data_id**		Returns the data ID (a unique identifier for the underlying data storage)
[const]	new Shapes ptr	**decompose_convex**	(int preferred_orientation = Polygon#PO_any)	Decomposes the region into convex pieces.
[const]	new Region ptr	**decompose_conve**	(int preferred_orientation = Polygon#PO_any)	Decomposes the region into convex pieces into a region.
[const]	new Shapes ptr	**decompose_trapezoids**	(int mode = Polygon#TD_simple)	Decomposes the region into trapezoids.
[const]	new Region ptr	**decompose_trapez**	(int mode = Polygon#TD_simple)	Decomposes the region into trapezoids.
[const]	Region	**delaunay**		Computes a constrained Delaunay triangulation from the given region
[const]	Region	**delaunay**	(double max_area, double min_b = 1)	Computes a refined, constrained Delaunay triangulation from the given region
	void	**disable_progress**		Disable progress reporting
[const]	new Region ptr	**dup**		Creates a copy of self
[const,iter]	Polygon	**each**		Returns each polygon of the region

[const,iter]	Polygon	**each_merged**		Returns each merged polygon of the region
[const]	Edges	**edges**	(EdgeMode mode = All)	Returns an edge collection representing all edges of the polygons in this region
	void	**enable_progress**	(string label)	Enable progress reporting
	void	**enable_properties**		Enables properties for the given container.
[const]	EdgePairs	**enclosed_check**	(const Region other, unsigned int d, bool whole_edges = false, Metrics metrics = Euclidian, variant ignore_angle = default, variant min_projection = 0, variant max_projection = max, bool shielded = true, Region::OppositeFilter opposite_filter = NoOppositeFilter, Region::RectFilter rect_filter = NoRectFilter, bool negative = false, PropertyConstraint property_constraint = IgnoreProperties, ZeroDistanceMode zero_distance_mode = IncludeZeroDistanceWhenTouchi	Performs an inside check with options
[const]	EdgePairs	**enclosing_check**	(const Region other, unsigned int d, bool whole_edges = false, Metrics metrics = Euclidian, variant ignore_angle = default, variant min_projection = 0, variant max_projection = max, bool shielded = true, Region::OppositeFilter opposite_filter = NoOppositeFilter, Region::RectFilter rect_filter = NoRectFilter, bool negative = false, PropertyConstraint property_constraint = IgnoreProperties, ZeroDistanceMode zero_distance_mode = IncludeZeroDistanceWhenTouching)	Performs an enclosing check with options
[const]	Region	**extents**		Returns a region with the bounding boxes of the polygons
[const]	Region	**extents**	(int d)	Returns a region with the enlarged bounding boxes of the polygons

[const]	Region	**extents**	(int dx, int dy)	Returns a region with the enlarged bounding boxes of the polygons
[const]	void	**fill**	(Cell ptr in_cell, unsigned int fill_cell_index, const Box fc_box, const Point ptr origin = (0, 0), Region ptr remaining_parts = nil, const Vector fill_margin = 0,0, Region ptr remaining_polygons = nil, const Box glue_box = ())	A mapping of Cell#fill_region to the Region class
[const]	void	**fill**	(Cell ptr in_cell, unsigned int fill_cell_index, const Box fc_origin, const Vector row_step, const Vector column_step, const Point ptr origin = (0, 0), Region ptr remaining_parts = nil, const Vector fill_margin = 0,0, Region ptr remaining_polygons = nil, const Box glue_box = ())	A mapping of Cell#fill_region to the Region class
[const]	void	**fill_multi**	(Cell ptr in_cell, unsigned int fill_cell_index, const Box fc_origin, const Vector row_step, const Vector column_step, const Vector fill_margin = 0,0, Region ptr remaining_polygons = nil, const Box glue_box = ())	A mapping of Cell#fill_region to the Region class
	void	**filter**	(const PolygonFilter ptr filter)	Applies a generic filter in place (replacing the polygons from the Region)
	void	**filter_properties**	(variant[] keys)	Filters properties by certain keys.
[const]	Region	**filtered**	(const PolygonFilter ptr filtered)	Applies a generic filter and returns a filtered copy
	Region	**flatten**		Explicitly flattens a region
[const]	EdgePairs	**grid_check**	(int gx, int gy)	Returns a marker for all vertices not being on the given grid
[const]	bool	**has_valid_polygons?**		Returns true if the region is flat and individual polygons can be accessed randomly
[const]	unsigned long	**hier_count**		Returns the (hierarchical) number of polygons in the region
[const]	Region	**holes**		Returns the holes of the region

[const]	Region	**hulls**		Returns the hulls of the region
[const]	Region	**in**	(const Region other)	Returns all polygons which are members of the other region
[const]	Region[]	**in_and_out**	(const Region other)	Returns all polygons which are members and not members of the other region
	void	**insert**	(const Box box)	Inserts a box
	void	**insert**	(const Polygon polygon)	Inserts a polygon
	void	**insert**	(const SimplePolygon polygon)	Inserts a simple polygon
	void	**insert**	(const Path path)	Inserts a path
	void	**insert**	(RecursiveShapeIterator shape_iterator)	Inserts all shapes delivered by the recursive shape iterator into this region
	void	**insert**	(RecursiveShapeIterator shape_iterator, ICplxTrans trans)	Inserts all shapes delivered by the recursive shape iterator into this region with a transformation
	void	**insert**	(Polygon[] array)	Inserts all polygons from the array into this region
	void	**insert**	(const Region region)	Inserts all polygons from the other region into this region
	void	**insert**	(const Shapes shapes)	Inserts all polygons from the shape collection into this region
	void	**insert**	(const Shapes shapes, const Trans trans)	Inserts all polygons from the shape collection into this region with transformation
	void	**insert**	(const Shapes shapes, const ICplxTrans trans)	Inserts all polygons from the shape collection into this region with complex transformation
[const]	void	**insert_into**	(Layout ptr layout, unsigned int cell_index, unsigned int layer)	Inserts this region into the given layout, below the given cell and into the given layer.
[const]	Region	**inside**	(const Region other)	Returns the polygons of this region which are completely inside polygons from the other region
[const]	EdgePairs	**inside_check**	(const Region other, unsigned int d, bool whole_edges = false, Metrics metrics = Euclidian, variant ignore_angle = default, variant min_projection = 0, variant max_projection = max, bool shielded = true, Region::OppositeFilter opposite_filter = NoOppositeFilter,	Performs an inside check with options

			Region::RectFilter rect_filter = NoRectFilter, bool negative = false, PropertyConstraint property_constraint = IgnoreProperties, ZeroDistanceMode zero_distance_mode = IncludeZeroDistanceWhenTouchi	
[const]	Region	**interacting**	(const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Returns the polygons of this region which overlap or touch polygons from the other region
[const]	Region	**interacting**	(const Edges other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Returns the polygons of this region which overlap or touch edges from the edge collection
[const]	Region	**interacting**	(const Texts other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Returns the polygons of this region which overlap or touch texts
[const]	bool	**is_box?**		Returns true, if the region is a simple box
[const]	bool	**is_deep?**		Returns true if the region is a deep (hierarchical) one
[const]	bool	**is_empty?**		Returns true if the region is empty
[const]	bool	**is_merged?**		Returns true if the region is merged
[const]	EdgePairs	**isolated_check**	(unsigned int d, bool whole_edges = false, Metrics metrics = Euclidian, variant ignore_angle = default, variant min_projection = 0, variant max_projection = max, bool shielded = true, Region::OppositeFilter opposite_filter = NoOppositeFilter, Region::RectFilter rect_filter = NoRectFilter, bool negative = false, PropertyConstraint property_constraint = IgnoreProperties, ZeroDistanceMode zero_distance_mode = IncludeZeroDistanceWhenTouchi	Performs a space check between edges of different polygons with options
[const]	Region	**join**	(const Region other)	Returns the combined region of self and the other region
	Region	**join_with**	(const Region other)	Adds the polygons of the other region to self

	void	**map_properties**	(map<variant,variant> key_map)	Maps properties by name key.
[const]	Region	**members_of**	(const Region other)	Returns all polygons which are members of the other region
	Region	**merge**		Merge the region
	Region	**merge**	(int min_wc)	Merge the region with options
	Region	**merge**	(bool min_coherence, int min_wc)	Merge the region with options
[const]	Region	**merged**		Returns the merged region
	Region	**merged**	(int min_wc)	Returns the merged region (with options)
	Region	**merged**	(bool min_coherence, int min_wc)	Returns the merged region (with options)
	void	**merged_semantics=**	(bool f)	Enables or disables merged semantics
[const]	bool	**merged_semantics**		Gets a flag indicating whether merged semantics is enabled
	void	**min_coherence=**	(bool f)	Enable or disable minimum coherence
[const]	bool	**min_coherence?**		Gets a flag indicating whether minimum coherence is selected
[const]	Region	**minkowski_sum**	(const Edge e)	Compute the Minkowski sum of the region and an edge
[const]	Region	**minkowski_sum**	(const Polygon p)	Compute the Minkowski sum of the region and a polygon
[const]	Region	**minkowski_sum**	(const Box b)	Compute the Minkowski sum of the region and a box
[const]	Region	**minkowski_sum**	(Point[] b)	Compute the Minkowski sum of the region and a contour of points (a trace)
	Region	**move**	(const Vector v)	Moves the region
	Region	**move**	(int x, int y)	Moves the region
[const]	Region	**moved**	(const Vector v)	Returns the moved region (does not modify self)
[const]	Region	**moved**	(int x, int y)	Returns the moved region (does not modify self)
[const]	Region	**nets**	(LayoutToNetlist extracted, variant net_prop_name = nil, const Net ptr[] ptr net_filter = nil)	Pulls the net shapes from a LayoutToNetlist database

[const]	Region	**non_rectangles**		Returns all polygons which are not rectangles
[const]	Region	**non_rectilinear**		Returns all polygons which are not rectilinear
[const]	Region	**non_squares**		Returns all polygons which are not squares
[const]	Region	**not**	(const Region other, PropertyConstraint property_constraint = IgnoreProperties)	Returns the boolean NOT between self and the other region
[const]	Region	**not_covering**	(const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Returns the polygons of this region which are not completely covering polygons from the other region
[const]	Region	**not_in**	(const Region other)	Returns all polygons which are not members of the other region
[const]	Region	**not_inside**	(const Region other)	Returns the polygons of this region which are not completely inside polygons from the other region
[const]	Region	**not_interacting**	(const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Returns the polygons of this region which do not overlap or touch polygons from the other region
[const]	Region	**not_interacting**	(const Edges other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Returns the polygons of this region which do not overlap or touch edges from the edge collection
[const]	Region	**not_interacting**	(const Texts other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Returns the polygons of this region which do not overlap or touch texts
[const]	Region	**not_members_of**	(const Region other)	Returns all polygons which are not members of the other region
[const]	Region	**not_outside**	(const Region other)	Returns the polygons of this region which are not completely outside polygons from the other region
[const]	Region	**not_overlapping**	(const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Returns the polygons of this region which do not overlap polygons from the other region
	Region	**not_with**	(const Region other, PropertyConstraint property_constraint = IgnoreProperties)	Performs the boolean NOT between self and the other region in-place (modifying self)

[const]	EdgePairs	**notch_check**	(unsigned int d, bool whole_edges = false, Metrics metrics = Euclidian, variant ignore_angle = default, variant min_projection = 0, variant max_projection = max, bool shielded = true, bool negative = false, PropertyConstraint property_constraint = IgnoreProperties, ZeroDistanceMode zero_distance_mode = IncludeZeroDistanceWhenTouchi	Performs a space check between edges of the same polygon with options
[const]	Region	**or**	(const Region other)	Returns the boolean OR between self and the other region
	Region	**or_with**	(const Region other)	Performs the boolean OR between self and the other region in-place (modifying self)
[const]	Region	**outside**	(const Region other)	Returns the polygons of this region which are completely outside polygons from the other region
[const]	EdgePairs	**overlap_check**	(const Region other, unsigned int d, bool whole_edges = false, Metrics metrics = Euclidian, variant ignore_angle = default, variant min_projection = 0, variant max_projection = max, bool shielded = true, Region::OppositeFilter opposite_filter = NoOppositeFilter, Region::RectFilter rect_filter = NoRectFilter, bool negative = false, PropertyConstraint property_constraint = IgnoreProperties, ZeroDistanceMode zero_distance_mode = IncludeZeroDistanceWhenTouchi	Performs an overlap check with options
[const]	Region	**overlapping**	(const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Returns the polygons of this region which overlap polygons from the other region
[const]	unsigned long	**perimeter**		The total perimeter of the polygons
[const]	unsigned long	**perimeter**	(const Box rect)	The total perimeter of the polygons (restricted to a rectangle)
	void	**process**	(const PolygonOperator ptr process)	Applies a generic polygon processor in place (replacing the polygons from the Region)

[const]	Region	**processed**	(const PolygonOperator ptr processed)	Applies a generic polygon processor and returns a processed copy
[const]	EdgePairs	**processed**	(const PolygonToEdgePairOperator ptr processed)	Applies a generic polygon-to-edge-pair processor and returns an edge pair collection with the results
[const]	Edges	**processed**	(const PolygonToEdgeOperator ptr processed)	Applies a generic polygon-to-edge processor and returns an edge collection with the results
[const]	Region	**pull_inside**	(const Region other)	Returns all polygons of "other" which are inside polygons of this region
[const]	Region	**pull_interacting**	(const Region other)	Returns all polygons of "other" which are interacting with (overlapping, touching) polygons of this region
[const]	Edges	**pull_interacting**	(const Edges other)	Returns all edges of "other" which are interacting with polygons of this region
[const]	Texts	**pull_interacting**	(const Texts other)	Returns all texts of "other" which are interacting with polygons of this region
[const]	Region	**pull_overlapping**	(const Region other)	Returns all polygons of "other" which are overlapping polygons of this region
[const]	double[][]	**rasterize**	(const Point origin, const Vector pixel_size, unsigned int nx, unsigned int ny)	A grayscale rasterizer delivering the area covered per pixel
[const]	double[][]	**rasterize**	(const Point origin, const Vector pixel_distance, const Vector pixel_size, unsigned int nx, unsigned int ny)	A version of 'rasterize' that allows a pixel step distance which is larger than the pixel size
[const]	Region	**rectangles**		Returns all polygons which are rectangles
[const]	Region	**rectilinear**		Returns all polygons which are rectilinear
	void	**remove_properties**		Removes properties for the given container.
	void	**round_corners**	(double r_inner, double r_outer, unsigned int n)	Corner rounding
[const]	Region	**rounded_corners**	(double r_inner, double r_outer, unsigned int n)	Corner rounding
	void	**scale_and_snap**	(int gx, int mx, int dx, int gy, int my,	Scales and snaps the region to the given grid

			int dy)	
[const]	Region	**scaled_and_snapped**	(int gx, int mx, int dx, int gy, int my, int dy)	Returns the scaled and snapped region
	Region	**select_covering**	(const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Selects the polygons of this region which are completely covering polygons from the other region
	Region	**select_inside**	(const Region other)	Selects the polygons of this region which are completely inside polygons from the other region
	Region	**select_interacting**	(const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Selects the polygons from this region which overlap or touch polygons from the other region
	Region	**select_interacting**	(const Edges other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Selects the polygons from this region which overlap or touch edges from the edge collection
	Region	**select_interacting**	(const Texts other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Selects the polygons of this region which overlap or touch texts
	Region	**select_not_covering**	(const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Selects the polygons of this region which are not completely covering polygons from the other region
	Region	**select_not_inside**	(const Region other)	Selects the polygons of this region which are not completely inside polygons from the other region
	Region	**select_not_interacting**	(const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Selects the polygons from this region which do not overlap or touch polygons from the other region
	Region	**select_not_interact**	(const Edges other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Selects the polygons from this region which do not overlap or touch edges from the edge collection
	Region	**select_not_interacting**	(const Texts other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Selects the polygons of this region which do not overlap or touch texts
	Region	**select_not_outside**	(const Region other)	Selects the polygons of this region which are not completely outside polygons from the other region

	Region	**select_not_overlapping**	(const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Selects the polygons from this region which do not overlap polygons from the other region
	Region	**select_outside**	(const Region other)	Selects the polygons of this region which are completely outside polygons from the other region
	Region	**select_overlapping**	(const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Selects the polygons from this region which overlap polygons from the other region
[const]	EdgePairs	**separation_check**	(const Region other, unsigned int d, bool whole_edges = false, Metrics metrics = Euclidian, variant ignore_angle = default, variant min_projection = 0, variant max_projection = max, bool shielded = true, Region::OppositeFilter opposite_filter = NoOppositeFilter, Region::RectFilter rect_filter = NoRectFilter, bool negative = false, PropertyConstraint property_constraint = IgnoreProperties, ZeroDistanceMode zero_distance_mode = IncludeZeroDistanceWhenTouchi	Performs a separation check with options
	Region	**size**	(int dx, int dy, unsigned int mode)	Anisotropic sizing (biasing)
	Region	**size**	(const Vector dv, unsigned int mode = 2)	Anisotropic sizing (biasing)
	Region	**size**	(int d, unsigned int mode = 2)	Isotropic sizing (biasing)
[const]	Region	**sized**	(int dx, int dy, unsigned int mode)	Returns the anisotropically sized region
[const]	Region	**sized**	(const Vector dv, unsigned int mode = 2)	Returns the (an)isotropically sized region
[const]	Region	**sized**	(int d, unsigned int mode = 2)	Returns the isotropically sized region
	void	**smooth**	(int d, bool keep_hv = false)	Smoothing
[const]	Region	**smoothed**	(int d,	Smoothing

			bool keep_hv = false)	
	void	**snap**	(int gx, int gy)	Snaps the region to the given grid
[const]	Region	**snapped**	(int gx, int gy)	Returns the snapped region
[const]	EdgePairs	**space_check**	(unsigned int d, bool whole_edges = false, Metrics metrics = Euclidian, variant ignore_angle = default, variant min_projection = 0, variant max_projection = max, bool shielded = true, Region::OppositeFilter opposite_filter = NoOppositeFilter, Region::RectFilter rect_filter = NoRectFilter, bool negative = false, PropertyConstraint property_constraint = IgnoreProperties, ZeroDistanceMode zero_distance_mode = IncludeZeroDistanceWhenTouching)	Performs a space check with options
[const]	Region[]	**split_covering**	(const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Returns the polygons of this region which are completely covering polygons from the other region and the ones which are not at the same time
[const]	Region[]	**split_inside**	(const Region other)	Returns the polygons of this region which are completely inside polygons from the other region and the ones which are not at the same time
[const]	Region[]	**split_interacting**	(const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Returns the polygons of this region which are interacting with polygons from the other region and the ones which are not at the same time
[const]	Region[]	**split_interacting**	(const Edges other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Returns the polygons of this region which are interacting with edges from the other edge collection and the ones which are not at the same time
[const]	Region[]	**split_interacting**	(const Texts other, unsigned long min_count = 1, unsigned long max_count = unlimited)	Returns the polygons of this region which are interacting with texts from the other text collection and the ones which are not at the same time
[const]	Region[]	**split_outside**	(const Region other)	Returns the polygons of this region which are completely outside polygons from the other region and the ones which are not at the same time
[const]	Region[]	**split_overlapping**	(const Region other, unsigned long min_count = 1,	Returns the polygons of this region which are overlapping with polygons

			unsigned long max_count = unlimited)	from the other region and the ones which are not at the same time
[const]	Region	**squares**		Returns all polygons which are squares
[const]	Region	**strange_polygon_c**		Returns a region containing those parts of polygons which are "strange"
	void	**strict_handling=**	(bool f)	Enables or disables strict handling
[const]	bool	**strict_handling?**		Gets a flag indicating whether merged semantics is enabled
	void	**swap**	(Region other)	Swap the contents of this region with the contents of another region
[const]	string	**to_s**		Converts the region to a string
[const]	string	**to_s**	(unsigned long max_count)	Converts the region to a string
	Region	**transform**	(const Trans t)	Transform the region (modifies self)
	Region	**transform**	(const ICplxTrans t)	Transform the region with a complex transformation (modifies self)
	Region	**transform**	(const IMatrix2d t)	Transform the region (modifies self)
	Region	**transform**	(const IMatrix3d t)	Transform the region (modifies self)
[const]	Region	**transformed**	(const Trans t)	Transforms the region
[const]	Region	**transformed**	(const ICplxTrans t)	Transforms the region with a complex transformation
[const]	Region	**transformed**	(const IMatrix2d t)	Transforms the region
[const]	Region	**transformed**	(const IMatrix3d t)	Transforms the region
[const]	EdgePairs	**width_check**	(unsigned int d, bool whole_edges = false, Metrics metrics = Euclidian, variant ignore_angle = default, variant min_projection = 0, variant max_projection = max, bool shielded = true, bool negative = false, PropertyConstraint property_constraint = IgnoreProperties, ZeroDistanceMode zero_distance_mode = IncludeZeroDistanceWhenTouchi	Performs a width check with options
[const]	EdgePairs	**with_angle**	(double angle, bool inverse)	Returns markers on every corner with the given angle (or not with the given angle)

[const]	EdgePairs	**with_angle**	(double amin, double amax, bool inverse)	Returns markers on every corner with an angle of more than amin and less than amax (or the opposite)
[const]	Region	**with_area**	(long area, bool inverse)	Filter the polygons by area
[const]	Region	**with_area**	(variant min_area, variant max_area, bool inverse)	Filter the polygons by area
[const]	Region	**with_area_ratio**	(double ratio, bool inverse)	Filters the polygons by the bounding box area to polygon area ratio
[const]	Region	**with_area_ratio**	(variant min_ratio, variant max_ratio, bool inverse, bool min_included = true, bool max_included = true)	Filters the polygons by the aspect ratio of their bounding boxes
[const]	Region	**with_bbox_aspect_ratio**	(double ratio, bool inverse)	Filters the polygons by the aspect ratio of their bounding boxes
[const]	Region	**with_bbox_aspect_**	(variant min_ratio, variant max_ratio, bool inverse, bool min_included = true, bool max_included = true)	Filters the polygons by the aspect ratio of their bounding boxes
[const]	Region	**with_bbox_height**	(unsigned int height, bool inverse)	Filter the polygons by bounding box height
[const]	Region	**with_bbox_height**	(variant min_height, variant max_height, bool inverse)	Filter the polygons by bounding box height
[const]	Region	**with_bbox_max**	(unsigned int dim, bool inverse)	Filter the polygons by bounding box width or height, whichever is larger
[const]	Region	**with_bbox_max**	(variant min_dim, variant max_dim, bool inverse)	Filter the polygons by bounding box width or height, whichever is larger
[const]	Region	**with_bbox_min**	(unsigned int dim, bool inverse)	Filter the polygons by bounding box width or height, whichever is smaller
[const]	Region	**with_bbox_min**	(variant min_dim, variant max_dim, bool inverse)	Filter the polygons by bounding box width or height, whichever is smaller
[const]	Region	**with_bbox_width**	(unsigned int width, bool inverse)	Filter the polygons by bounding box width
[const]	Region	**with_bbox_width**	(variant min_width, variant max_width, bool inverse)	Filter the polygons by bounding box width
[const]	Region	**with_holes**	(unsigned long nholes, bool inverse)	Filters the polygons by their number of holes

[const]	Region	**with_holes**	(variant min_bholes, variant max_nholes, bool inverse)	Filter the polygons by their number of holes
[const]	Region	**with_perimeter**	(unsigned long perimeter, bool inverse)	Filter the polygons by perimeter
[const]	Region	**with_perimeter**	(variant min_perimeter, variant max_perimeter, bool inverse)	Filter the polygons by perimeter
[const]	Region	**with_relative_height**	(double ratio, bool inverse)	Filters the polygons by the ratio of height to width
[const]	Region	**with_relative_heigh**	(variant min_ratio, variant max_ratio, bool inverse, bool min_included = true, bool max_included = true)	Filters the polygons by the bounding box height to width ratio
[const]	void	**write**	(string filename)	Writes the region to a file
[const]	Region	**xor**	(const Region other)	Returns the boolean XOR between self and the other region
	Region	**xor_with**	(const Region other)	Performs the boolean XOR between self and the other region in-place (modifying self)
[const]	Region	**|**	(const Region other)	Returns the boolean OR between self and the other region
	Region	**|=**	(const Region other)	Performs the boolean OR between self and the other region in-place (modifying self)

Public static methods and constants

[static,const]	EdgeMode	**All**	Selects all edges
[static,const]	EdgeMode	**Concave**	Selects only concave edges
[static,const]	EdgeMode	**Convex**	Selects only convex edges
[static,const]	PropertyConstraint	**DifferentPropertiesConstraint**	Specifies to consider shapes only if their user properties are different
[static,const]	PropertyConstraint	**DifferentPropertiesConst**	Specifies to consider shapes only if their user properties are different
[static,const]	Metrics	**Euclidian**	Specifies Euclidian metrics for the check functions
[static,const]	Region::RectFilter	**FourSidesAllowed**	Allow errors when on all sides
[static,const]	PropertyConstraint	**IgnoreProperties**	Specifies to ignore properties

[static,const]	ZeroDistanceMode	**IncludeZeroDistanceWhe**	Specifies that check functions should include edges when they are collinear and touch
[static,const]	ZeroDistanceMode	**IncludeZeroDistanceWhenOverlapping**	Specifies that check functions should include edges when they overlap
[static,const]	ZeroDistanceMode	**IncludeZeroDistanceWhe**	Specifies that check functions should include edges when they touch
[static,const]	ZeroDistanceMode	**NeverIncludeZeroDistance**	Specifies that check functions should never include edges with zero distance.
[static,const]	Region::OppositeFilter	**NoOppositeFilter**	No opposite filtering
[static,const]	PropertyConstraint	**NoPropertyConstraint**	Specifies not to apply any property constraint
[static,const]	Region::RectFilter	**NoRectFilter**	Specifies no filtering
[static,const]	EdgeMode	**NotConcave**	Selects only edges which are not concave
[static,const]	EdgeMode	**NotConvex**	Selects only edges which are not convex
[static,const]	Region::OppositeFilter	**NotOpposite**	Only errors NOT appearing on opposite sides of a figure will be reported
[static,const]	EdgeMode	**NotStep**	Selects only edges which are not steps
[static,const]	EdgeMode	**NotStepIn**	Selects only edges which are not steps leading inside
[static,const]	EdgeMode	**NotStepOut**	Selects only edges which are not steps leading outside
[static,const]	Region::RectFilter	**OneSideAllowed**	Allow errors on one side
[static,const]	Region::OppositeFilter	**OnlyOpposite**	Only errors appearing on opposite sides of a figure will be reported
[static,const]	Metrics	**Projection**	Specifies projected distance metrics for the check functions
[static,const]	PropertyConstraint	**SamePropertiesConstrai**	Specifies to consider shapes only if their user properties are the same
[static,const]	PropertyConstraint	**SamePropertiesConstraintDrop**	Specifies to consider shapes only if their user properties are the same
[static,const]	Metrics	**Square**	Specifies square metrics for the check functions
[static,const]	EdgeMode	**Step**	Selects only step edges leading inside or outside
[static,const]	EdgeMode	**StepIn**	Selects only step edges leading inside
[static,const]	EdgeMode	**StepOut**	Selects only step edges leading outside

Detailed description

&

Signature: *[const]* Region **&** (const Region other)

Description: Returns the boolean AND between self and the other region

Returns: The result of the boolean AND operation

This method will compute the boolean AND (intersection) between two regions. The result is often but not necessarily always merged.

&=

Signature: Region **&=** (const Region other)

Description: Performs the boolean AND between self and the other region in-place (modifying self)

Returns: The region after modification (self)

This method will compute the boolean AND (intersection) between two regions. The result is often but not necessarily always merged.

Note that in Ruby, the '&=' operator actually does not exist, but is emulated by '&' followed by an assignment. This is less efficient than the in-place operation, so it is recommended to use 'and_with' instead.

+

Signature: *[const]* Region **+** (const Region other)

Description: Returns the combined region of self and the other region

Returns: The resulting region

This operator adds the polygons of the other region to self and returns a new combined region. This usually creates unmerged regions and polygons may overlap. Use merge if you want to ensure the result region is merged.

The 'join' alias has been introduced in version 0.28.12.

+=

Signature: Region **+=** (const Region other)

Description: Adds the polygons of the other region to self

Returns: The region after modification (self)

This operator adds the polygons of the other region to self. This usually creates unmerged regions and polygons may overlap. Use merge if you want to ensure the result region is merged.

Note that in Ruby, the '+=' operator actually does not exist, but is emulated by '+' followed by an assignment. This is less efficient than the in-place operation, so it is recommended to use 'join_with' instead.

The 'join_with' alias has been introduced in version 0.28.12.

-

Signature: *[const]* Region **-** (const Region other)

Description: Returns the boolean NOT between self and the other region

Returns: The result of the boolean NOT operation

This method will compute the boolean NOT (intersection) between two regions. The result is often but not necessarily always merged.

-=

Signature: Region **-=** (const Region other)

Description: Performs the boolean NOT between self and the other region in-place (modifying self)

Returns: The region after modification (self)

This method will compute the boolean NOT (intersection) between two regions. The result is often but not necessarily always merged.

Note that in Ruby, the '-=' operator actually does not exist, but is emulated by '-' followed by an assignment. This is less efficient than the in-place operation, so it is recommended to use 'not_with' instead.

All

Signature: *[static,const]* EdgeMode **All**

Description: Selects all edges

Python specific notes:

The object exposes a readable attribute 'All'. This is the getter.

Concave

Signature: *[static,const]* EdgeMode **Concave**

Description: Selects only concave edges

Python specific notes:
The object exposes a readable attribute 'Concave'. This is the getter.

Convex

Signature: *[static,const]* EdgeMode **Convex**

Description: Selects only convex edges

Python specific notes:
The object exposes a readable attribute 'Convex'. This is the getter.

DifferentPropertiesConstraint

Signature: *[static,const]* PropertyConstraint **DifferentPropertiesConstraint**

Description: Specifies to consider shapes only if their user properties are different

When using this constraint - for example on a boolean operation - shapes are considered only if their user properties are different. Properties are generated on the output shapes where applicable.

Python specific notes:
The object exposes a readable attribute 'DifferentPropertiesConstraint'. This is the getter.

DifferentPropertiesConstr

Signature: *[static,const]* PropertyConstraint **DifferentPropertiesConstraintDrop**

Description: Specifies to consider shapes only if their user properties are different

When using this constraint - for example on a boolean operation - shapes are considered only if their user properties are the same. No properties are generated on the output shapes.

Python specific notes:
The object exposes a readable attribute 'DifferentPropertiesConstraintDrop'. This is the getter.

Euclidian

Signature: *[static,const]* Metrics **Euclidian**

Description: Specifies Euclidian metrics for the check functions

This value can be used for the metrics parameter in the check functions, i.e. width_check. This value specifies Euclidian metrics, i.e. the distance between two points is measured by:

```
d = sqrt(dx^2 + dy^2)
```

All points within a circle with radius d around one point are considered to have a smaller distance than d.

Python specific notes:
The object exposes a readable attribute 'Euclidian'. This is the getter.

FourSidesAllowed

Signature: *[static,const]* Region::RectFilter **FourSidesAllowed**

Description: Allow errors when on all sides

Python specific notes:
The object exposes a readable attribute 'FourSidesAllowed'. This is the getter.

IgnoreProperties

Signature: *[static,const]* PropertyConstraint **IgnoreProperties**

Description: Specifies to ignore properties

When using this constraint - for example on a boolean operation - properties are ignored and are not generated in the output.

Python specific notes:
The object exposes a readable attribute 'IgnoreProperties'. This is the getter.

IncludeZeroDistanceWhe

Signature: *[static,const]* ZeroDistanceMode **IncludeZeroDistanceWhenCollinearAndTouching**

Description: Specifies that check functions should include edges when they are collinear and touch

With this specification, the check functions will also check edges if they share at least one common point and are collinear. This is the mode that includes checking the 'kissing corner' cases when the kissing edges are collinear. This mode was default up to version 0.28.

Python specific notes:
The object exposes a readable attribute 'IncludeZeroDistanceWhenCollinearAndTouching'. This is the getter.

IncludeZeroDistanceWhenOverlapping

Signature: *[static,const]* ZeroDistanceMode **IncludeZeroDistanceWhenOverlapping**

Description: Specifies that check functions should include edges when they overlap

With this specification, the check functions will also check edges which are collinear and share more than a single point. This is the mode that excludes the 'kissing corner' cases.

Python specific notes:
The object exposes a readable attribute 'IncludeZeroDistanceWhenOverlapping'. This is the getter.

IncludeZeroDistanceWhe

Signature: *[static,const]* ZeroDistanceMode **IncludeZeroDistanceWhenTouching**

Description: Specifies that check functions should include edges when they touch

With this specification, the check functions will also check edges if they share at least one common point. This is the mode that includes checking the 'kissing corner' cases. This mode is default for version 0.28.16 and later.

Python specific notes:
The object exposes a readable attribute 'IncludeZeroDistanceWhenTouching'. This is the getter.

NeverIncludeZeroDistance

Signature: *[static,const]* ZeroDistanceMode **NeverIncludeZeroDistance**

Description: Specifies that check functions should never include edges with zero distance.

With this specification, the check functions will ignore edges which are collinear or touch.

Python specific notes:
The object exposes a readable attribute 'NeverIncludeZeroDistance'. This is the getter.

NoOppositeFilter

Signature: *[static,const]* Region::OppositeFilter **NoOppositeFilter**

Description: No opposite filtering

Python specific notes:
The object exposes a readable attribute 'NoOppositeFilter'. This is the getter.

NoPropertyConstraint

Signature: *[static,const]* PropertyConstraint **NoPropertyConstraint**

Description: Specifies not to apply any property constraint

When using this constraint - for example on a boolean operation - shapes are considered regardless of their user properties. Properties are generated on the output shapes where applicable.

Python specific notes:
The object exposes a readable attribute 'NoPropertyConstraint'. This is the getter.

NoRectFilter

Signature: *[static,const]* Region::RectFilter **NoRectFilter**

Description: Specifies no filtering

Python specific notes:
The object exposes a readable attribute 'NoRectFilter'. This is the getter.

NotConcave

Signature: *[static,const]* EdgeMode **NotConcave**

Description: Selects only edges which are not concave

Python specific notes:
The object exposes a readable attribute 'NotConcave'. This is the getter.

NotConvex

Signature: *[static,const]* EdgeMode **NotConvex**

Description: Selects only edges which are not convex

Python specific notes:
The object exposes a readable attribute 'NotConvex'. This is the getter.

NotOpposite

Signature: *[static,const]* Region::OppositeFilter **NotOpposite**

Description: Only errors NOT appearing on opposite sides of a figure will be reported

Python specific notes:
The object exposes a readable attribute 'NotOpposite'. This is the getter.

NotStep

Signature: *[static,const]* EdgeMode **NotStep**

Description: Selects only edges which are not steps

Python specific notes:
The object exposes a readable attribute 'NotStep'. This is the getter.

NotStepIn

Signature: *[static,const]* EdgeMode **NotStepIn**

Description: Selects only edges which are not steps leading inside

Python specific notes:
The object exposes a readable attribute 'NotStepIn'. This is the getter.

NotStepOut

Signature: *[static,const]* EdgeMode **NotStepOut**

Description: Selects only edges which are not steps leading outside

Python specific notes:
The object exposes a readable attribute 'NotStepOut'. This is the getter.

OneSideAllowed

Signature: *[static,const]* Region::RectFilter **OneSideAllowed**

Description: Allow errors on one side

Python specific notes:
The object exposes a readable attribute 'OneSideAllowed'. This is the getter.

OnlyOpposite

Signature: *[static,const]* Region::OppositeFilter **OnlyOpposite**

Description: Only errors appearing on opposite sides of a figure will be reported

Python specific notes:
The object exposes a readable attribute 'OnlyOpposite'. This is the getter.

Projection

Signature: *[static,const]* Metrics **Projection**

Description: Specifies projected distance metrics for the check functions

This value can be used for the metrics parameter in the check functions, i.e. width_check. This value specifies projected metrics, i.e. the distance is defined as the minimum distance measured perpendicular to one edge. That implies that the distance is defined only where two edges have a non-vanishing projection onto each other.

Python specific notes:
The object exposes a readable attribute 'Projection'. This is the getter.

SamePropertiesConstrain

Signature: *[static,const]* PropertyConstraint **SamePropertiesConstraint**

Description: Specifies to consider shapes only if their user properties are the same

When using this constraint - for example on a boolean operation - shapes are considered only if their user properties are the same. Properties are generated on the output shapes where applicable.

Python specific notes:
The object exposes a readable attribute 'SamePropertiesConstraint'. This is the getter.

SamePropertiesConstraintDrop

Signature: *[static,const]* PropertyConstraint **SamePropertiesConstraintDrop**

Description: Specifies to consider shapes only if their user properties are the same

When using this constraint - for example on a boolean operation - shapes are considered only if their user properties are the same. No properties are generated on the output shapes.

Python specific notes:
The object exposes a readable attribute 'SamePropertiesConstraintDrop'. This is the getter.

Square

Signature: *[static,const]* Metrics **Square**

Description: Specifies square metrics for the check functions

This value can be used for the metrics parameter in the check functions, i.e. width_check. This value specifies square metrics, i.e. the distance between two points is measured by:

```
d = max(abs(dx), abs(dy))
```

All points within a square with length 2*d around one point are considered to have a smaller distance than d in this metrics.

Python specific notes:
The object exposes a readable attribute 'Square'. This is the getter.

Step

Signature: *[static,const]* EdgeMode **Step**

Description: Selects only step edges leading inside or outside

Python specific notes:
The object exposes a readable attribute 'Step'. This is the getter.

StepIn

Signature: *[static,const]* EdgeMode **StepIn**

Description: Selects only step edges leading inside

Python specific notes:
The object exposes a readable attribute 'StepIn'. This is the getter.

StepOut

Signature: *[static,const]* EdgeMode **StepOut**

Description: Selects only step edges leading outside

Python specific notes:
The object exposes a readable attribute 'StepOut'. This is the getter.

ThreeSidesAllowed

Signature: *[static,const]* Region::RectFilter **ThreeSidesAllowed**

Description: Allow errors when on three sides

Python specific notes:
The object exposes a readable attribute 'ThreeSidesAllowed'. This is the getter.

TwoConnectedSidesAllowed

Signature: *[static,const]* Region::RectFilter **TwoConnectedSidesAllowed**

Description: Allow errors on two sides ("L" configuration)

Python specific notes:
The object exposes a readable attribute 'TwoConnectedSidesAllowed'. This is the getter.

TwoOppositeSidesAllowed

Signature: *[static,const]* Region::RectFilter **TwoOppositeSidesAllowed**

Description: Allow errors on two opposite sides

Python specific notes:
The object exposes a readable attribute 'TwoOppositeSidesAllowed'. This is the getter.

TwoSidesAllowed

Signature: *[static,const]* Region::RectFilter **TwoSidesAllowed**

Description: Allow errors on two sides (not specified which)

Python specific notes:
The object exposes a readable attribute 'TwoSidesAllowed'. This is the getter.

[]

Signature: *[const]* const Polygon ptr **[]** (unsigned long n)

Description: Returns the nth polygon of the region

This method returns nil if the index is out of range. It is available for flat regions only - i.e. those for which has_valid_polygons? is true. Use flatten to explicitly flatten a region. This method returns the raw polygon (not merged polygons, even if merged semantics is enabled).

The each iterator is the more general approach to access the polygons.

^

Signature: *[const]* Region **^** (const Region other)

Description: Returns the boolean XOR between self and the other region

Returns: The result of the boolean XOR operation

This method will compute the boolean XOR (intersection) between two regions. The result is often but not necessarily always merged.

The 'xor' alias has been introduced in version 0.28.12.

^=

Signature: Region **^=** (const Region other)

Description: Performs the boolean XOR between self and the other region in-place (modifying self)

Returns: The region after modification (self)

This method will compute the boolean XOR (intersection) between two regions. The result is often but not necessarily always merged.

Note that in Ruby, the '^=' operator actually does not exist, but is emulated by '^' followed by an assignment. This is less efficient than the in-place operation, so it is recommended to use 'xor_with' instead.

The 'xor_with' alias has been introduced in version 0.28.12.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

and

Signature: *[const]* Region **and** (const Region other, PropertyConstraint property_constraint = IgnoreProperties)

Description: Returns the boolean AND between self and the other region

Returns: The result of the boolean AND operation

This method will compute the boolean AND (intersection) between two regions. The result is often but not necessarily always merged. It allows specification of a property constaint - e.g. only performing the boolean operation between shapes with the same user properties.

This variant has been introduced in version 0.28.4.

Python specific notes:
This attribute is available as 'and_' in Python.

and_with

Signature: Region **and_with** (const Region other, PropertyConstraint property_constraint = IgnoreProperties)

Description: Performs the boolean AND between self and the other region in-place (modifying self)

Returns: The region after modification (self)

This method will compute the boolean AND (intersection) between two regions. The result is often but not necessarily always merged. It allows specification of a property constaint - e.g. only performing the boolean operation between shapes with the same user properties.

This variant has been introduced in version 0.28.4.

andnot

Signature: *[const]* Region[] **andnot** (const Region other, PropertyConstraint property_constraint = IgnoreProperties)

Description: Returns the boolean AND and NOT between self and the other region

Returns: A two-element array of regions with the first one being the AND result and the second one being the NOT result

This method will compute the boolean AND and NOT between two regions simultaneously. Because this requires a single sweep only, using this method is faster than doing AND and NOT separately.

This method has been added in version 0.27.

area

(1) Signature: *[const]* long **area**

Description: The area of the region

Merged semantics applies for this method (see merged_semantics= for a description of this concept)
If merged semantics is not enabled, overlapping areas are counted twice.

(2) Signature: *[const]* long **area** (const Box rect)

Description: The area of the region (restricted to a rectangle)

This version will compute the area of the shapes, restricting the computation to the given rectangle.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)
If merged semantics is not enabled, overlapping areas are counted twice.

assign

Signature: void **assign** (const Region other)

Description: Assigns another object to self

base_verbosity

Signature: *[const]* unsigned int **base_verbosity**

Description: Gets the minimum verbosity for timing reports

See base_verbosity= for details.

This method has been introduced in version 0.26.

Python specific notes:
The object exposes a readable attribute 'base_verbosity'. This is the getter.

base_verbosity=

Signature: void **base_verbosity=** (int verbosity)

Description: Sets the minimum verbosity for timing reports

Timing reports will be given only if the verbosity is larger than this value. Detailed reports will be given when the verbosity is more than this value plus 10. In binary operations, the base verbosity of the first argument is considered.

This method has been introduced in version 0.26.

Python specific notes:
The object exposes a writable attribute 'base_verbosity'. This is the setter.

bbox

Signature: *[const]* Box **bbox**

Description: Return the bounding box of the region

The bounding box is the box enclosing all points of all polygons.

break

Signature: void **break** (unsigned long max_vertex_count, double max_area_ratio = 0)

Description: Breaks the polygons of the region into smaller ones

There are two criteria for splitting a polygon: a polygon is split into parts with less then 'max_vertex_count' points and an bounding box-to-polygon area ratio less than 'max_area_ratio'. The area ratio is supposed to render polygons whose bounding box is a better approximation. This applies for example to 'L' shape polygons.

Using a value of 0 for either limit means that the respective limit isn't checked. Breaking happens by cutting the polygons into parts at 'good' locations. The algorithm does not have a specific goal to minimize the number of parts for example. The only goal is to achieve parts within the given limits.

This method has been introduced in version 0.26.

Python specific notes:
This attribute is available as 'break_' in Python.

clear

Signature: void **clear**

Description: Clears the region

complex_op

Signature: variant **complex_op** (CompoundRegionOperationNode ptr node, PropertyConstraint property_constraint = IgnoreProperties)

Description: Executes a complex operation (see CompoundRegionOperationNode for details)

This method has been introduced in version 0.27. The 'property_constraint' parameter controls whether properties are considered: with 'SamePropertiesConstraint' the operation is only applied between shapes with identical properties. With 'DifferentPropertiesConstraint' only between shapes with different properties. This option has been introduced in version 0.28.4.

corners

Signature: *[const]* Region **corners** (double angle_min = -180, double angle_max = 180, int dim = 1, bool include_min_angle = true, bool include_max_angle = true)

Description: This method will select all corners whose attached edges satisfy the angle condition.

The angle values specify a range of angles: all corners whose attached edges form an angle between angle_min and angle_max will be reported boxes with 2*dim x 2*dim dimension. The default dimension is 2x2 DBU.

If 'include_angle_min' is true, the angle condition is >= min. angle, otherwise it is > min. angle. Same for 'include_angle_,ax' and the max. angle.

The angle is measured between the incoming and the outcoming edge in mathematical sense: a positive value is a turn left while a negative value is a turn right. Since polygon contours are oriented clockwise, positive angles will report concave corners while negative ones report convex ones.

A similar function that reports corners as point-like edges is corners_dots.

This method has been introduced in version 0.25. 'include_min_angle' and 'include_max_angle' have been added in version 0.27.

corners_dots

Signature: *[const]* Edges **corners_dots** (double angle_start = -180, double angle_end = 180, bool include_min_angle = true, bool include_max_angle = true)

Description: This method will select all corners whose attached edges satisfy the angle condition.

This method is similar to corners, but delivers an Edges collection with dot-like edges for each corner.

This method has been introduced in version 0.25. 'include_min_angle' and 'include_max_angle' have been added in version 0.27.

corners_edge_pairs

Signature: *[const]* EdgePairs **corners_edge_pairs** (double angle_start = -180, double angle_end = 180, bool include_min_angle = true, bool include_max_angle = true)

Description: This method will select all corners whose attached edges satisfy the angle condition.

This method is similar to corners, but delivers an EdgePairs collection with an edge pairs for each corner. The first edge is the incoming edge of the corner, the second one the outgoing edge.

This method has been introduced in version 0.27.1.

count

Signature: *[const]* unsigned long **count**

Description: Returns the (flat) number of polygons in the region

This returns the number of raw polygons (not merged polygons if merged semantics is enabled). The count is computed 'as if flat', i.e. polygons inside a cell are multiplied by the number of times a cell is instantiated.

The 'count' alias has been provided in version 0.26 to avoid ambiguity with the 'size' method which applies a geometrical bias.

Python specific notes:
This method is also available as 'len(object)'.

covering

Signature: *[const]* Region **covering** (const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Returns the polygons of this region which are completely covering polygons from the other region

Returns: A new region containing the polygons which are covering polygons from the other region

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This attribute is sometimes called 'enclosing' instead of 'covering', but this term is reserved for the respective DRC function.

This method has been introduced in version 0.27.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

data_id

Signature: *[const]* unsigned long **data_id**

Description: Returns the data ID (a unique identifier for the underlying data storage)

This method has been added in version 0.26.

decompose_convex

Signature: *[const]* new Shapes ptr **decompose_convex** (int preferred_orientation = Polygon#PO_any)

Description: Decomposes the region into convex pieces.

This method will return a Shapes container that holds a decomposition of the region into convex, simple polygons. See Polygon#decompose_convex for details. If you want Region output, you should use decompose_convex_to_region.

This method has been introduced in version 0.25.

decompose_convex_to_reg

Signature: *[const]* new Region ptr **decompose_convex_to_region** (int preferred_orientation = Polygon#PO_any)

Description: Decomposes the region into convex pieces into a region.

This method is identical to decompose_convex, but delivers a Region object.

This method has been introduced in version 0.25.

decompose_trapezoids

Signature: *[const]* new Shapes ptr **decompose_trapezoids** (int mode = Polygon#TD_simple)

Description: Decomposes the region into trapezoids.

This method will return a Shapes container that holds a decomposition of the region into trapezoids. See Polygon#decompose_trapezoids for details. If you want Region output, you should use decompose_trapezoids_to_region.

This method has been introduced in version 0.25.

decompose_trapezoids_to_

Signature: *[const]* new Region ptr **decompose_trapezoids_to_region** (int mode = Polygon#TD_simple)

Description: Decomposes the region into trapezoids.

This method is identical to decompose_trapezoids, but delivers a Region object.

This method has been introduced in version 0.25.

delaunay

(1) Signature: *[const]* Region **delaunay**

Description: Computes a constrained Delaunay triangulation from the given region

Returns: A new region holding the triangles of the constrained Delaunay triangulation.

Note that the result is a region in raw mode as otherwise the triangles are likely to get merged later on.

This method has been introduced in version 0.29.

(2) Signature: *[const]* Region **delaunay** (double max_area, double min_b = 1)

Description: Computes a refined, constrained Delaunay triangulation from the given region

Returns: A new region holding the triangles of the refined, constrained Delaunay triangulation.

Refinement is implemented by Chew's second algorithm. A maximum area can be given. Triangles larger than this area will be split. In addition 'skinny' triangles will be resolved where possible. 'skinny'

is defined in terms of shortest edge to circumcircle radius ratio (b). A minimum number for b can be given. The default of 1.0 corresponds to a minimum angle of 30 degree and is usually a good choice. The algorithm is stable up to roughly 1.2 which corresponds to a minimum angle of abouth 37 degree.

The area value is given in terms of DBU units. Picking a value of 0.0 for area and min b will make the implementation skip the refinement step. In that case, the results are identical to the standard constrained Delaunay triangulation.

Note that the result is a region in raw mode as otherwise the triangles are likely to get merged later on.

This method has been introduced in version 0.29.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

disable_progress

Signature: void **disable_progress**

Description: Disable progress reporting

Calling this method will disable progress reporting. See enable_progress.

dup

Signature: *[const]* new Region ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

each

Signature: *[const,iter]* Polygon **each**

Description: Returns each polygon of the region

This returns the raw polygons (not merged polygons if merged semantics is enabled).

Python specific notes:
This method enables iteration of the object.

each_merged

Signature: *[const,iter]* Polygon **each_merged**

Description: Returns each merged polygon of the region

This returns the raw polygons if merged semantics is disabled or the merged ones if merged semantics is enabled.

edges

Signature: *[const]* Edges **edges** (EdgeMode mode = All)

Description: Returns an edge collection representing all edges of the polygons in this region

This method will decompose the polygons into the individual edges. Edges making up the hulls of the polygons are oriented clockwise while edges making up the holes are oriented counterclockwise.

The 'mode' parameter allows selecting specific edges, such as convex or concave ones. By default, all edges are selected.

The edge collection returned can be manipulated in various ways. See Edges for a description of the features of the edge collection.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

The mode argument has been added in version 0.29.

enable_progress

Signature: void **enable_progress** (string label)

Description: Enable progress reporting

After calling this method, the region will report the progress through a progress bar while expensive operations are running. The label is a text which is put in front of the progress bar. Using a progress bar will imply a performance penalty of a few percent typically.

enable_properties

Signature: void **enable_properties**

Description: Enables properties for the given container.

This method has an effect mainly on original layers and will import properties from such layers. By default, properties are not enabled on original layers. Alternatively you can apply filter_properties or map_properties to enable properties with a specific name key.

This method has been introduced in version 0.28.4.

enclosed_check

Signature: *[const]* EdgePairs **enclosed_check** (const Region other, unsigned int d, bool whole_edges = false, Metrics metrics = Euclidian, variant ignore_angle = default, variant min_projection = 0, variant max_projection = max, bool shielded = true, Region::OppositeFilter opposite_filter = NoOppositeFilter, Region::RectFilter rect_filter = NoRectFilter, bool negative = false, PropertyConstraint property_constraint = IgnoreProperties, ZeroDistanceMode zero_distance_mode = IncludeZeroDistanceWhenTouching)

Description: Performs an inside check with options

d:	The minimum distance for which the polygons are checked
other:	The other region against which to check
whole_edges:	If true, deliver the whole edges
metrics:	Specify the metrics type
ignore_angle:	The angle above which no check is performed
min_projection:	The lower threshold of the projected length of one edge onto another
max_projection:	The upper limit of the projected length of one edge onto another
opposite_filter:	Specifies a filter mode for errors happening on opposite sides of inputs shapes
rect_filter:	Specifies an error filter for rectangular input shapes
negative:	Negative output from the first input
property_constraint:	Specifies whether to consider only shapes with a certain property relation
zero_distance_mode:	Specifies how to handle edges with zero distance

If "whole_edges" is true, the resulting EdgePairs collection will receive the whole edges which contribute in the width check.

"metrics" can be one of the constants Euclidian, Square or Projection. See there for a description of these constants.

"ignore_angle" specifies the angle limit of two edges. If two edges form an angle equal or above the given value, they will not contribute in the check. Setting this value to 90 (the default) will exclude edges with an angle of 90 degree or more from the check. Use nil for this value to select the default.

"min_projection" and "max_projection" allow selecting edges by their projected value upon each other. It is sufficient if the projection of one edge on the other matches the specified condition. The projected length must be larger or equal to "min_projection" and less than "max_projection". If you don't want to specify one limit, pass nil to the respective value.

"shielded" controls whether shielding is applied. Shielding means that rule violations are not detected 'through' other features. Measurements are only made where the opposite edge is unobstructed. Shielding often is not optional as a rule violation in shielded case automatically comes with rule violations between the original and the shielding features. If not necessary, shielding can be disabled by setting this flag to false. In general, this will improve performance somewhat.

"opposite_filter" specifies whether to require or reject errors happening on opposite sides of a figure. "rect_filter" allows suppressing specific error configurations on rectangular input figures.

If "negative" is true, only edges from the first input are output as pseudo edge-pairs where the distance is larger or equal to the limit. This is a way to flag the parts of the first input where the distance to the second input is bigger. Note that only the first input's edges are output. The output is still edge pairs, but each edge pair contains one edge from the original input and the reverse version of the edge as the second edge.

Merged semantics applies for the input of this method (see merged_semantics= for a description of this concept)

The 'shielded', 'negative', 'not_opposite' and 'rect_sides' options have been introduced in version 0.27. The interpretation of the 'negative' flag has been restriced to first-layout only output in 0.27.1. The 'enclosed_check' alias was introduced in version 0.27.5. 'property_constraint' has been added in version 0.28.4. 'zero_distance_mode' has been added in version 0.29.

enclosing_check

Signature: *[const]* EdgePairs **enclosing_check** (const Region other, unsigned int d, bool whole_edges = false, Metrics metrics = Euclidian, variant ignore_angle = default, variant min_projection = 0, variant max_projection = max, bool shielded = true, Region::OppositeFilter opposite_filter = NoOppositeFilter, Region::RectFilter rect_filter = NoRectFilter, bool negative = false, PropertyConstraint property_constraint = IgnoreProperties, ZeroDistanceMode zero_distance_mode = IncludeZeroDistanceWhenTouching)

Description: Performs an enclosing check with options

d:	The minimum enclosing distance for which the polygons are checked
other:	The other region against which to check
whole_edges:	If true, deliver the whole edges
metrics:	Specify the metrics type
ignore_angle:	The angle above which no check is performed
min_projection:	The lower threshold of the projected length of one edge onto another
max_projection:	The upper limit of the projected length of one edge onto another
opposite_filter:	Specifies a filter mode for errors happening on opposite sides of inputs shapes
rect_filter:	Specifies an error filter for rectangular input shapes
negative:	Negative output from the first input
property_constraint:	Specifies whether to consider only shapes with a certain property relation
zero_distance_mode:	Specifies how to handle edges with zero distance

If "whole_edges" is true, the resulting EdgePairs collection will receive the whole edges which contribute in the width check.

"metrics" can be one of the constants Euclidian, Square or Projection. See there for a description of these constants.

"ignore_angle" specifies the angle limit of two edges. If two edges form an angle equal or above the given value, they will not contribute in the check. Setting this value to 90 (the default) will exclude edges with an angle of 90 degree or more from the check. Use nil for this value to select the default.

"min_projection" and "max_projection" allow selecting edges by their projected value upon each other. It is sufficient if the projection of one edge on the other matches the specified condition. The projected length must be larger or equal to "min_projection" and less than "max_projection". If you don't want to specify one limit, pass nil to the respective value.

"shielded" controls whether shielding is applied. Shielding means that rule violations are not detected 'through' other features. Measurements are only made where the opposite edge is unobstructed. Shielding often is not optional as a rule violation in shielded case automatically comes with rule violations between the original and the shielding features. If not necessary, shielding can be disabled by setting this flag to false. In general, this will improve performance somewhat.

"opposite_filter" specifies whether to require or reject errors happening on opposite sides of a figure. "rect_filter" allows suppressing specific error configurations on rectangular input figures.

If "negative" is true, only edges from the first input are output as pseudo edge-pairs where the enclosure is larger or equal to the limit. This is a way to flag the parts of the first input where the enclosure vs. the second input is bigger. Note that only the first input's edges are output. The output is still edge pairs, but each edge pair contains one edge from the original input and the reverse version of the edge as the second edge.

Merged semantics applies for the input of this method (see merged_semantics= for a description of this concept)

The 'shielded', 'negative', 'not_opposite' and 'rect_sides' options have been introduced in version 0.27. The interpretation of the 'negative' flag has been restriced to first-layout only output in 0.27.1. 'property_constraint' has been added in version 0.28.4. 'zero_distance_mode' has been added in version 0.29.

extents

(1) Signature: *[const]* Region **extents**

Description: Returns a region with the bounding boxes of the polygons

This method will return a region consisting of the bounding boxes of the polygons. The boxes will not be merged, so it is possible to determine overlaps of these boxes for example.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

(2) Signature: *[const]* Region **extents** (int d)

Description: Returns a region with the enlarged bounding boxes of the polygons

This method will return a region consisting of the bounding boxes of the polygons enlarged by the given distance d. The enlargement is specified per edge, i.e the width and height will be increased by 2*d. The boxes will not be merged, so it is possible to determine overlaps of these boxes for example.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

(3) Signature: *[const]* Region **extents** (int dx, int dy)

Description: Returns a region with the enlarged bounding boxes of the polygons

This method will return a region consisting of the bounding boxes of the polygons enlarged by the given distance dx in x direction and dy in y direction. The enlargement is specified per edge, i.e the width will be increased by 2*dx. The boxes will not be merged, so it is possible to determine overlaps of these boxes for example.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

fill

(1) Signature: *[const]* void **fill** (Cell ptr in_cell, unsigned int fill_cell_index, const Box fc_box, const Point ptr origin = (0, 0), Region ptr remaining_parts = nil, const Vector fill_margin = 0,0, Region ptr remaining_polygons = nil, const Box glue_box = ())

Description: A mapping of Cell#fill_region to the Region class

This method is equivalent to Cell#fill_region, but is based on Region (with the cell being the first parameter).

This method has been introduced in version 0.27.

(2) Signature: *[const]* void **fill** (Cell ptr in_cell, unsigned int fill_cell_index, const Box fc_origin, const Vector row_step, const Vector column_step, const Point ptr origin = (0, 0), Region ptr remaining_parts = nil, const Vector fill_margin = 0,0, Region ptr remaining_polygons = nil, const Box glue_box = ())

Description: A mapping of Cell#fill_region to the Region class

This method is equivalent to Cell#fill_region, but is based on Region (with the cell being the first parameter).

This method has been introduced in version 0.27.

fill_multi

Signature: *[const]* void **fill_multi** (Cell ptr in_cell, unsigned int fill_cell_index, const Box fc_origin, const Vector row_step, const Vector column_step, const Vector fill_margin = 0,0, Region ptr remaining_polygons = nil, const Box glue_box = ())

Description: A mapping of Cell#fill_region to the Region class

This method is equivalent to Cell#fill_region, but is based on Region (with the cell being the first parameter).

This method has been introduced in version 0.27.

filter

Signature: void **filter** (const PolygonFilter ptr filter)

Description: Applies a generic filter in place (replacing the polygons from the Region)

See PolygonFilter for a description of this feature.

This method has been introduced in version 0.29.

filter_properties

Signature: void **filter_properties** (variant[] keys)

Description: Filters properties by certain keys.

Calling this method on a container will reduce the properties to values with name keys from the 'keys' list. As a side effect, this method enables properties on original layers.

This method has been introduced in version 0.28.4.

filtered

Signature: *[const]* Region **filtered** (const PolygonFilter ptr filtered)

Description: Applies a generic filter and returns a filtered copy

See PolygonFilter for a description of this feature.

This method has been introduced in version 0.29.

flatten

Signature: Region **flatten**

Description: Explicitly flattens a region

If the region is already flat (i.e. has_valid_polygons? returns true), this method will not change it.

Returns 'self', so this method can be used in a dot concatenation.

This method has been introduced in version 0.26.

grid_check

Signature: *[const]* EdgePairs **grid_check** (int gx, int gy)

Description: Returns a marker for all vertices not being on the given grid

This method will return an edge pair object for every vertex whose x coordinate is not a multiple of gx or whose y coordinate is not a multiple of gy. The edge pair objects contain two edges consisting of the same single point - the original vertex.

If gx or gy is 0 or less, the grid is not checked in that direction.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

has_valid_polygons?

Signature: *[const]* bool **has_valid_polygons?**

Description: Returns true if the region is flat and individual polygons can be accessed randomly

This method has been introduced in version 0.26.

hier_count

Signature: *[const]* unsigned long **hier_count**

Description: Returns the (hierarchical) number of polygons in the region

This returns the number of raw polygons (not merged polygons if merged semantics is enabled). The count is computed 'hierarchical', i.e. polygons inside a cell are counted once even if the cell is instantiated multiple times.

This method has been introduced in version 0.27.

holes

Signature: *[const]* Region **holes**

Description: Returns the holes of the region

This method returns all holes as filled polygons.

Merged semantics applies for this method (see merged_semantics= for a description of this concept) If merge semantics is not enabled, the holes may not be detected if the polygons are taken from a hole-less representation (i.e. GDS2 file). Use explicit merge (merge method) in order to merge the polygons and detect holes.

hulls

Signature: *[const]* Region **hulls**

Description: Returns the hulls of the region

This method returns all hulls as polygons. The holes will be removed (filled). Merged semantics applies for this method (see merged_semantics= for a description of this concept) If merge semantics is not enabled, the hull may also enclose holes if the polygons are taken from a hole-less representation (i.e. GDS2 file). Use explicit merge (merge method) in order to merge the polygons and detect holes.

in

Signature: *[const]* Region **in** (const Region other)

Description: Returns all polygons which are members of the other region

This method returns all polygons in self which can be found in the other region as well with exactly the same geometry.

Python specific notes:
This attribute is available as 'in_' in Python.

in_and_out

Signature: *[const]* Region[] **in_and_out** (const Region other)

Description: Returns all polygons which are members and not members of the other region

This method is equivalent to calling members_of and not_members_of, but delivers both results at the same time and is more efficient than two separate calls. The first element returned is the members_of part, the second is the not_members_of part.

This method has been introduced in version 0.28.

insert

(1) Signature: void **insert** (const Box box)

Description: Inserts a box

Inserts a box into the region.

(2) Signature: void **insert** (const Polygon polygon)

Description: Inserts a polygon

Inserts a polygon into the region.

(3) Signature: void **insert** (const SimplePolygon polygon)

Description: Inserts a simple polygon

Inserts a simple polygon into the region.

(4) Signature: void **insert** (const Path path)

Description: Inserts a path

Inserts a path into the region.

(5) Signature: void **insert** (RecursiveShapeIterator shape_iterator)

Description: Inserts all shapes delivered by the recursive shape iterator into this region

This method will insert all shapes delivered by the shape iterator and insert them into the region. Text objects and edges are not inserted, because they cannot be converted to polygons.

(6) Signature: void **insert** (RecursiveShapeIterator shape_iterator, ICplxTrans trans)

Description: Inserts all shapes delivered by the recursive shape iterator into this region with a transformation

This method will insert all shapes delivered by the shape iterator and insert them into the region. Text objects and edges are not inserted, because they cannot be converted to polygons. This variant will apply the given transformation to the shapes. This is useful to scale the shapes to a specific database unit for example.

(7) Signature: void **insert** (Polygon[] array)

Description: Inserts all polygons from the array into this region

(8) Signature: void **insert** (const Region region)

Description: Inserts all polygons from the other region into this region

This method has been introduced in version 0.25.

(9) Signature: void **insert** (const Shapes shapes)

Description: Inserts all polygons from the shape collection into this region

This method takes each "polygon-like" shape from the shape collection and inserts this shape into the region. Paths and boxes are converted to polygons during this process. Edges and text objects are ignored.

This method has been introduced in version 0.25.

(10) Signature: void **insert** (const Shapes shapes, const Trans trans)

Description: Inserts all polygons from the shape collection into this region with transformation

This method takes each "polygon-like" shape from the shape collection and inserts this shape into the region after applying the given transformation. Paths and boxes are converted to polygons during this process. Edges and text objects are ignored.

This method has been introduced in version 0.25.

(11) Signature: void **insert** (const Shapes shapes, const ICplxTrans trans)

Description: Inserts all polygons from the shape collection into this region with complex transformation

This method takes each "polygon-like" shape from the shape collection and inserts this shape into the region after applying the given complex transformation. Paths and boxes are converted to polygons during this process. Edges and text objects are ignored.

This method has been introduced in version 0.25.

insert_into

Signature: *[const]* void **insert_into** (Layout ptr layout, unsigned int cell_index, unsigned int layer)

Description: Inserts this region into the given layout, below the given cell and into the given layer.

If the region is a hierarchical one, a suitable hierarchy will be built below the top cell or and existing hierarchy will be reused.

This method has been introduced in version 0.26.

inside

Signature: *[const]* Region **inside** (const Region other)

Description: Returns the polygons of this region which are completely inside polygons from the other region

Returns:	A new region containing the polygons which are inside polygons from the other region

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

inside_check

Signature: *[const]* EdgePairs **inside_check** (const Region other, unsigned int d, bool whole_edges = false, Metrics metrics = Euclidian, variant ignore_angle = default, variant min_projection = 0, variant max_projection = max, bool shielded = true, Region::OppositeFilter opposite_filter = NoOppositeFilter, Region::RectFilter rect_filter = NoRectFilter, bool negative = false, PropertyConstraint property_constraint = IgnoreProperties, ZeroDistanceMode zero_distance_mode = IncludeZeroDistanceWhenTouching)

Description: Performs an inside check with options

d:	The minimum distance for which the polygons are checked
other:	The other region against which to check
whole_edges:	If true, deliver the whole edges
metrics:	Specify the metrics type
ignore_angle:	The angle above which no check is performed
min_projection:	The lower threshold of the projected length of one edge onto another

max_projection:	The upper limit of the projected length of one edge onto another
opposite_filter:	Specifies a filter mode for errors happening on opposite sides of inputs shapes
rect_filter:	Specifies an error filter for rectangular input shapes
negative:	Negative output from the first input
property_constraint:	Specifies whether to consider only shapes with a certain property relation
zero_distance_mode:	Specifies how to handle edges with zero distance

If "whole_edges" is true, the resulting EdgePairs collection will receive the whole edges which contribute in the width check.

"metrics" can be one of the constants Euclidian, Square or Projection. See there for a description of these constants.

"ignore_angle" specifies the angle limit of two edges. If two edges form an angle equal or above the given value, they will not contribute in the check. Setting this value to 90 (the default) will exclude edges with an angle of 90 degree or more from the check. Use nil for this value to select the default.

"min_projection" and "max_projection" allow selecting edges by their projected value upon each other. It is sufficient if the projection of one edge on the other matches the specified condition. The projected length must be larger or equal to "min_projection" and less than "max_projection". If you don't want to specify one limit, pass nil to the respective value.

"shielded" controls whether shielding is applied. Shielding means that rule violations are not detected 'through' other features. Measurements are only made where the opposite edge is unobstructed. Shielding often is not optional as a rule violation in shielded case automatically comes with rule violations between the original and the shielding features. If not necessary, shielding can be disabled by setting this flag to false. In general, this will improve performance somewhat.

"opposite_filter" specifies whether to require or reject errors happening on opposite sides of a figure. "rect_filter" allows suppressing specific error configurations on rectangular input figures.

If "negative" is true, only edges from the first input are output as pseudo edge-pairs where the distance is larger or equal to the limit. This is a way to flag the parts of the first input where the distance to the second input is bigger. Note that only the first input's edges are output. The output is still edge pairs, but each edge pair contains one edge from the original input and the reverse version of the edge as the second edge.

Merged semantics applies for the input of this method (see merged_semantics= for a description of this concept)

The 'shielded', 'negative', 'not_opposite' and 'rect_sides' options have been introduced in version 0.27. The interpretation of the 'negative' flag has been restriced to first-layout only output in 0.27.1. The 'enclosed_check' alias was introduced in version 0.27.5. 'property_constraint' has been added in version 0.28.4. 'zero_distance_mode' has been added in version 0.29.

interacting

(1) Signature: *[const]* Region **interacting** (const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Returns the polygons of this region which overlap or touch polygons from the other region

Returns:	A new region containing the polygons overlapping or touching polygons from the other region

'min_count' and 'max_count' impose a constraint on the number of times a polygon of this region has to interact with (different) polygons of the other region to make the polygon selected. A polygon is selected by this method if the number of polygons interacting with a polygon of this region is between min_count and max_count (including max_count).

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

The min_count and max_count arguments have been added in version 0.27.

(2) Signature: *[const]* Region **interacting** (const Edges other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Returns the polygons of this region which overlap or touch edges from the edge collection

Returns: A new region containing the polygons overlapping or touching edges from the edge collection

'min_count' and 'max_count' impose a constraint on the number of times a polygon of this region has to interact with edges of the edge collection to make the polygon selected. A polygon is selected by this method if the number of edges interacting with the polygon is between min_count and max_count (including max_count).

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.25. The min_count and max_count arguments have been added in version 0.27.

(3) Signature: *[const]* Region **interacting** (const Texts other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Returns the polygons of this region which overlap or touch texts

Returns: A new region containing the polygons overlapping or touching texts

'min_count' and 'max_count' impose a constraint on the number of times a polygon of this region has to interact with texts of the text collection to make the polygon selected. A polygon is selected by this method if the number of texts interacting with the polygon is between min_count and max_count (including max_count).

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.27

is_box?

Signature: *[const]* bool **is_box?**

Description: Returns true, if the region is a simple box

Returns: True if the region is a box.

This method does not apply implicit merging if merge semantics is enabled. If the region is not merged, this method may return false even if the merged region would be a box.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_deep?

Signature: *[const]* bool **is_deep?**

Description: Returns true if the region is a deep (hierarchical) one

This method has been added in version 0.26.

is_empty?

Signature: *[const]* bool **is_empty?**

Description: Returns true if the region is empty

is_merged?

Signature: *[const]* bool **is_merged?**

Description: Returns true if the region is merged

If the region is merged, polygons will not touch or overlap. You can ensure merged state by calling merge.

isolated_check

Signature: *[const]* EdgePairs **isolated_check** (unsigned int d, bool whole_edges = false, Metrics metrics = Euclidian, variant ignore_angle = default, variant min_projection = 0, variant max_projection = max, bool shielded = true, Region::OppositeFilter opposite_filter = NoOppositeFilter, Region::RectFilter rect_filter = NoRectFilter, bool negative = false, PropertyConstraint property_constraint = IgnoreProperties, ZeroDistanceMode zero_distance_mode = IncludeZeroDistanceWhenTouching)

Description: Performs a space check between edges of different polygons with options

d:	The minimum space for which the polygons are checked
whole_edges:	If true, deliver the whole edges
metrics:	Specify the metrics type
ignore_angle:	The angle above which no check is performed
min_projection:	The lower threshold of the projected length of one edge onto another
max_projection:	The upper limit of the projected length of one edge onto another
opposite_filter:	Specifies a filter mode for errors happening on opposite sides of inputs shapes
rect_filter:	Specifies an error filter for rectangular input shapes
negative:	If true, edges not violation the condition will be output as pseudo-edge pairs
property_constraint:	Specifies whether to consider only shapes with a certain property relation
zero_distance_mode:	Specifies how to handle edges with zero distance

If "whole_edges" is true, the resulting EdgePairs collection will receive the whole edges which contribute in the width check.

"metrics" can be one of the constants Euclidian, Square or Projection. See there for a description of these constants.

"ignore_angle" specifies the angle limit of two edges. If two edges form an angle equal or above the given value, they will not contribute in the check. Setting this value to 90 (the default) will exclude edges with an angle of 90 degree or more from the check. Use nil for this value to select the default.

"min_projection" and "max_projection" allow selecting edges by their projected value upon each other. It is sufficient if the projection of one edge on the other matches the specified condition. The projected length must be larger or equal to "min_projection" and less than "max_projection". If you don't want to specify one limit, pass nil to the respective value.

"shielded" controls whether shielding is applied. Shielding means that rule violations are not detected 'through' other features. Measurements are only made where the opposite edge is unobstructed. Shielding often is not optional as a rule violation in shielded case automatically comes with rule violations between the original and the shielding features. If not necessary, shielding can be disabled by setting this flag to false. In general, this will improve performance somewhat.

"opposite_filter" specifies whether to require or reject errors happening on opposite sides of a figure. "rect_filter" allows suppressing specific error configurations on rectangular input figures.

Merged semantics applies for the input of this method (see merged_semantics= for a description of this concept)

The 'shielded', 'negative', 'not_opposite' and 'rect_sides' options have been introduced in version 0.27. 'property_constraint' has been added in version 0.28.4. 'zero_distance_mode' has been added in version 0.29.

join

Signature: *[const]* Region **join** (const Region other)

Description: Returns the combined region of self and the other region

Returns: The resulting region

This operator adds the polygons of the other region to self and returns a new combined region. This usually creates unmerged regions and polygons may overlap. Use merge if you want to ensure the result region is merged.

The 'join' alias has been introduced in version 0.28.12.

join_with

Signature: Region **join_with** (const Region other)

Description: Adds the polygons of the other region to self

Returns: The region after modification (self)

This operator adds the polygons of the other region to self. This usually creates unmerged regions and polygons may overlap. Use merge if you want to ensure the result region is merged.

Note that in Ruby, the '+=' operator actually does not exist, but is emulated by '+' followed by an assignment. This is less efficient than the in-place operation, so it is recommended to use 'join_with' instead.

The 'join_with' alias has been introduced in version 0.28.12.

map_properties

Signature: void **map_properties** (map<variant,variant> key_map)

Description: Maps properties by name key.

Calling this method on a container will reduce the properties to values with name keys from the 'keys' hash and renames the properties. Properties not listed in the key map will be removed. As a side effect, this method enables properties on original layers.

This method has been introduced in version 0.28.4.

members_of

Signature: *[const]* Region **members_of** (const Region other)

Description: Returns all polygons which are members of the other region

This method returns all polygons in self which can be found in the other region as well with exactly the same geometry.

Python specific notes:
This attribute is available as 'in_' in Python.

merge

(1) Signature: Region **merge**

Description: Merge the region

Returns: The region after is has been merged (self).

Merging removes overlaps and joins touching polygons. If the region is already merged, this method does nothing

(2) Signature: Region **merge** (int min_wc)

Description: Merge the region with options

min_wc: Overlap selection

Returns: The region after is has been merged (self).

Merging removes overlaps and joins touching polygons. This version provides one additional option: "min_wc" controls whether output is only produced if multiple polygons overlap. The value specifies the number of polygons that need to overlap. A value of 2 means that output is only produced if two or more polygons overlap.

This method is equivalent to "merge(false, min_wc).

(3) Signature: Region **merge** (bool min_coherence, int min_wc)

Description: Merge the region with options

min_coherence:	A flag indicating whether the resulting polygons shall have minimum coherence
min_wc:	Overlap selection
Returns:	The region after is has been merged (self).

Merging removes overlaps and joins touching polygons. This version provides two additional options: if "min_coherence" is set to true, "kissing corners" are resolved by producing separate polygons. "min_wc" controls whether output is only produced if multiple polygons overlap. The value specifies the number of polygons that need to overlap. A value of 2 means that output is only produced if two or more polygons overlap.

merged

(1) Signature: *[const]* Region **merged**

Description: Returns the merged region

Returns:	The region after is has been merged.

Merging removes overlaps and joins touching polygons. If the region is already merged, this method does nothing. In contrast to merge, this method does not modify the region but returns a merged copy.

(2) Signature: Region **merged** (int min_wc)

Description: Returns the merged region (with options)

Returns:	The region after is has been merged.

This version provides one additional options: "min_wc" controls whether output is only produced if multiple polygons overlap. The value specifies the number of polygons that need to overlap. A value of 2 means that output is only produced if two or more polygons overlap.

This method is equivalent to "merged(false, min_wc)".

In contrast to merge, this method does not modify the region but returns a merged copy.

(3) Signature: Region **merged** (bool min_coherence, int min_wc)

Description: Returns the merged region (with options)

min_coherence:	A flag indicating whether the resulting polygons shall have minimum coherence
min_wc:	Overlap selection
Returns:	The region after is has been merged (self).

Merging removes overlaps and joins touching polygons. This version provides two additional options: if "min_coherence" is set to true, "kissing corners" are resolved by producing separate polygons. "min_wc" controls whether output is only produced if multiple polygons overlap. The value specifies the number of polygons that need to overlap. A value of 2 means that output is only produced if two or more polygons overlap.

In contrast to merge, this method does not modify the region but returns a merged copy.

merged_semantics=

Signature: void **merged_semantics=** (bool f)

Description: Enables or disables merged semantics

If merged semantics is enabled (the default), coherent polygons will be considered as single regions and artificial edges such as cut-lines will not be considered. Merged semantics thus is equivalent to considering coherent areas rather than single polygons

Python specific notes:
The object exposes a writable attribute 'merged_semantics'. This is the setter.

merged_semantics?

Signature: *[const]* bool **merged_semantics?**

Description: Gets a flag indicating whether merged semantics is enabled

See merged_semantics= for a description of this attribute.

Python specific notes:
The object exposes a readable attribute 'merged_semantics'. This is the getter.

min_coherence=

Signature: void **min_coherence=** (bool f)

Description: Enable or disable minimum coherence

If minimum coherence is set, the merge operations (explicit merge with merge or implicit merge through merged_semantics) are performed using minimum coherence mode. The coherence mode determines how kissing-corner situations are resolved. If minimum coherence is selected, they are resolved such that multiple polygons are created which touch at a corner).

The default setting is maximum coherence (min_coherence = false).

Python specific notes:
The object exposes a writable attribute 'min_coherence'. This is the setter.

min_coherence?

Signature: *[const]* bool **min_coherence?**

Description: Gets a flag indicating whether minimum coherence is selected

See min_coherence= for a description of this attribute.

Python specific notes:
The object exposes a readable attribute 'min_coherence'. This is the getter.

minkowski_sum

(1) Signature: *[const]* Region **minkowski_sum** (const Edge e)

Description: Compute the Minkowski sum of the region and an edge

e:	The edge.
Returns:	The new polygons representing the Minkowski sum with the edge e.

The Minkowski sum of a region and an edge basically results in the area covered when "dragging" the region along the line given by the edge. The effect is similar to drawing the line with a pencil that has the shape of the given region.

The resulting polygons are not merged. In order to remove overlaps, use the merge or merged method.Merged semantics applies for the input of this method (see merged_semantics= for a description of this concept)

(2) Signature: *[const]* Region **minkowski_sum** (const Polygon p)

Description: Compute the Minkowski sum of the region and a polygon

p:	The first argument.
Returns:	The new polygons representing the Minkowski sum of self and p.

The Minkowski sum of a region and a polygon is basically the result of "painting" the region with a pen that has the shape of the second polygon.

The resulting polygons are not merged. In order to remove overlaps, use the merge or merged method.Merged semantics applies for the input of this method (see merged_semantics= for a description of this concept)

(3) Signature: *[const]* Region **minkowski_sum** (const Box b)

Description: Compute the Minkowski sum of the region and a box

b:	The box.
Returns:	The new polygons representing the Minkowski sum of self and the box.

The result is equivalent to the region-with-polygon Minkowski sum with the box used as the second polygon.

The resulting polygons are not merged. In order to remove overlaps, use the merge or merged method.Merged semantics applies for the input of this method (see merged_semantics= for a description of this concept)

(4) Signature: *[const]* Region **minkowski_sum** (Point[] b)

Description: Compute the Minkowski sum of the region and a contour of points (a trace)

b:	The contour (a series of points forming the trace).
Returns:	The new polygons representing the Minkowski sum of self and the contour.

The Minkowski sum of a region and a contour basically results in the area covered when "dragging" the region along the contour. The effect is similar to drawing the contour with a pencil that has the shape of the given region.

The resulting polygons are not merged. In order to remove overlaps, use the merge or merged method.Merged semantics applies for the input of this method (see merged_semantics= for a description of this concept)

minkowsky_sum

(1) Signature: *[const]* Region **minkowsky_sum** (const Edge e)

Description: Compute the Minkowski sum of the region and an edge

e:	The edge.
Returns:	The new polygons representing the Minkowski sum with the edge e.

Use of this method is deprecated. Use minkowski_sum instead

The Minkowski sum of a region and an edge basically results in the area covered when "dragging" the region along the line given by the edge. The effect is similar to drawing the line with a pencil that has the shape of the given region.

The resulting polygons are not merged. In order to remove overlaps, use the merge or merged method.Merged semantics applies for the input of this method (see merged_semantics= for a description of this concept)

(2) Signature: *[const]* Region **minkowsky_sum** (const Polygon p)

Description: Compute the Minkowski sum of the region and a polygon

p:	The first argument.
Returns:	The new polygons representing the Minkowski sum of self and p.

Use of this method is deprecated. Use minkowski_sum instead

The Minkowski sum of a region and a polygon is basically the result of "painting" the region with a pen that has the shape of the second polygon.

The resulting polygons are not merged. In order to remove overlaps, use the merge or merged method.Merged semantics applies for the input of this method (see merged_semantics= for a description of this concept)

(3) Signature: *[const]* Region **minkowsky_sum** (const Box b)

Description: Compute the Minkowski sum of the region and a box

b:	The box.
Returns:	The new polygons representing the Minkowski sum of self and the box.

Use of this method is deprecated. Use minkowski_sum instead

The result is equivalent to the region-with-polygon Minkowski sum with the box used as the second polygon.

The resulting polygons are not merged. In order to remove overlaps, use the merge or merged method.Merged semantics applies for the input of this method (see merged_semantics= for a description of this concept)

(4) Signature: *[const]* Region **minkowsky_sum** (Point[] b)

Description: Compute the Minkowski sum of the region and a contour of points (a trace)

b:	The contour (a series of points forming the trace).
Returns:	The new polygons representing the Minkowski sum of self and the contour.

Use of this method is deprecated. Use minkowski_sum instead

The Minkowski sum of a region and a contour basically results in the area covered when "dragging" the region along the contour. The effect is similar to drawing the contour with a pencil that has the shape of the given region.

The resulting polygons are not merged. In order to remove overlaps, use the merge or merged method.Merged semantics applies for the input of this method (see merged_semantics= for a description of this concept)

move

(1) Signature: Region **move** (const Vector v)

Description: Moves the region

v:	The distance to move the region.
Returns:	The moved region (self).

Moves the polygon by the given offset and returns the moved region. The region is overwritten.

Starting with version 0.25 this method accepts a vector argument.

(2) Signature: Region **move** (int x, int y)

Description: Moves the region

x:	The x distance to move the region.
y:	The y distance to move the region.
Returns:	The moved region (self).

Moves the region by the given offset and returns the moved region. The region is overwritten.

moved

(1) Signature: *[const]* Region **moved** (const Vector v)

Description: Returns the moved region (does not modify self)

p:	The distance to move the region.
Returns:	The moved region.

Moves the region by the given offset and returns the moved region. The region is not modified.

Starting with version 0.25 this method accepts a vector argument.

(2) Signature: *[const]* Region **moved** (int x, int y)

Description: Returns the moved region (does not modify self)

x:	The x distance to move the region.
y:	The y distance to move the region.
Returns:	The moved region.

Moves the region by the given offset and returns the moved region. The region is not modified.

nets

Signature: *[const]* Region **nets** (LayoutToNetlist extracted, variant net_prop_name = nil, const Net ptr[] ptr net_filter = nil)

Description: Pulls the net shapes from a LayoutToNetlist database

This method will create a new layer with the net shapes from the LayoutToNetlist database, provided that this region was an input to the netlist extraction on this database.

A (circuit name, net name) tuple will be attached as properties to the shapes if 'net_prop_name' is given and not nil. This allows generating unique properties per shape, flagging the net the shape is on. This feature is good for performing net-dependent booleans and DRC checks.

A net filter can be provided with the 'net_filter' argument. If given, only nets from this set are produced. Example:

```
connect(metal1, via1)
connect(via1, metal2)

metal1_all_nets = metal1.nets
```

This method was introduced in version 0.28.4

new

(1) Signature: *[static]* new Region ptr **new**

Description: Default constructor

This constructor creates an empty region.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new Region ptr **new** (Polygon[] array)

Description: Constructor from a polygon array

This constructor creates a region from an array of polygons.

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new Region ptr **new** (const Box box)

Description: Box constructor

This constructor creates a region from a box.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new Region ptr **new** (const Polygon polygon)

Description: Polygon constructor

This constructor creates a region from a polygon.

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new Region ptr **new** (const SimplePolygon polygon)

Description: Simple polygon constructor

This constructor creates a region from a simple polygon.

Python specific notes:
This method is the default initializer of the object.

(6) Signature: *[static]* new Region ptr **new** (const Path path)

Description: Path constructor

This constructor creates a region from a path.

Python specific notes:
This method is the default initializer of the object.

(7) Signature: *[static]* new Region ptr **new** (const RecursiveShapeIterator shape_iterator)

Description: Constructor from a hierarchical shape set

This constructor creates a region from the shapes delivered by the given recursive shape iterator. Text objects and edges are not inserted, because they cannot be converted to polygons. This method allows feeding the shapes from a hierarchy of cells into the region.

```
layout = ... # a layout
cell   = ... # the index of the initial cell
layer  = ... # the index of the layer from where to take the shapes from
r = RBA::Region::new(layout.begin_shapes(cell, layer))
```

Python specific notes:
This method is the default initializer of the object.

(8) Signature: *[static]* new Region ptr **new** (const RecursiveShapeIterator shape_iterator, const ICplxTrans trans)

Description: Constructor from a hierarchical shape set with a transformation

This constructor creates a region from the shapes delivered by the given recursive shape iterator. Text objects and edges are not inserted, because they cannot be converted to polygons. On the delivered shapes it applies the given transformation. This method allows feeding the shapes from a hierarchy of cells into the region. The transformation is useful to scale to a specific database unit for example.

```
layout = ... # a layout
cell   = ... # the index of the initial cell
layer  = ... # the index of the layer from where to take the shapes from
dbu    = 0.1 # the target database unit
r = RBA::Region::new(layout.begin_shapes(cell, layer),
 RBA::ICplxTrans::new(layout.dbu / dbu))
```

Python specific notes:
This method is the default initializer of the object.

(9) Signature: *[static]* new Region ptr **new** (const Shapes shapes)

Description: Constructor from a shapes container

This constructor creates a region from the shapes container. Text objects and edges are not inserted, because they cannot be converted to polygons. This method allows feeding the shapes from a hierarchy of cells into the region.

This constructor has been introduced in version 0.25 and extended in version 0.29.

Python specific notes:
This method is the default initializer of the object.

(10) Signature: *[static]* new Region ptr **new** (const Shapes shapes, const ICplxTrans trans)

Description: Constructor from a shapes container with a transformation

This constructor creates a region from the shapes container after applying the transformation. Text objects and edges are not inserted, because they cannot be converted to polygons. This method allows feeding the shapes from a hierarchy of cells into the region.

This constructor variant has been introduced in version 0.29.

Python specific notes:
This method is the default initializer of the object.

(11) Signature: *[static]* new Region ptr **new** (const RecursiveShapeIterator shape_iterator, DeepShapeStore deep_shape_store, double area_ratio = 0, unsigned long max_vertex_count = 0)

Description: Constructor for a deep region from a hierarchical shape set

shape_iterator:	The recursive shape iterator which delivers the hierarchy to take
deep_shape_store:	The hierarchical heap (see there)
area_ratio:	The maximum ratio of bounding box to polygon area before polygons are split

This constructor creates a hierarchical region. Use a DeepShapeStore object to supply the hierarchical heap. See DeepShapeStore for more details.

'area_ratio' and 'max_vertex' supply two optimization parameters which control how big polygons are split to reduce the region's polygon complexity.

This method has been introduced in version 0.26.

Python specific notes:
This method is the default initializer of the object.

(12) Signature: *[static]* new Region ptr **new** (const RecursiveShapeIterator shape_iterator, DeepShapeStore deep_shape_store, const ICplxTrans trans, double area_ratio = 0, unsigned long max_vertex_count = 0)

Description: Constructor for a deep region from a hierarchical shape set

shape_iterator:	The recursive shape iterator which delivers the hierarchy to take
deep_shape_store:	The hierarchical heap (see there)
area_ratio:	The maximum ratio of bounding box to polygon area before polygons are split
trans:	The transformation to apply when storing the layout data

This constructor creates a hierarchical region. Use a DeepShapeStore object to supply the hierarchical heap. See DeepShapeStore for more details.

'area_ratio' and 'max_vertex' supply two optimization parameters which control how big polygons are split to reduce the region's polygon complexity.

The transformation is useful to scale to a specific database unit for example.

This method has been introduced in version 0.26.

Python specific notes:
This method is the default initializer of the object.

(13) Signature: *[static]* new Region ptr **new** (const RecursiveShapeIterator shape_iterator, string expr, bool as_pattern = true, int enl = 1)

Description: Constructor from a text set

shape_iterator:	The iterator from which to derive the texts
expr:	The selection string
as_pattern:	If true, the selection string is treated as a glob pattern. Otherwise the match is exact.
enl:	The per-side enlargement of the box to mark the text (1 gives a 2x2 DBU box)

This special constructor will create a region from the text objects delivered by the shape iterator. Each text object will give a small (non-empty) box that represents the text origin. Texts can be selected by their strings - either through a glob pattern or by exact comparison with the given string. The following options are available:

```
region = RBA::Region::new(iter, "*")           # all texts
region = RBA::Region::new(iter, "A*")          # all texts starting with an 'A'
region = RBA::Region::new(iter, "A*", false)   # all texts exactly matching
 'A*'
```

This method has been introduced in version 0.25. The enlargement parameter has been added in version 0.26.

Python specific notes:
This method is the default initializer of the object.

(14) Signature: *[static]* new Region ptr **new** (const RecursiveShapeIterator shape_iterator, DeepShapeStore dss, string expr, bool as_pattern = true, int enl = 1)

Description: Constructor from a text set

shape_iterator:	The iterator from which to derive the texts
dss:	The DeepShapeStore object that acts as a heap for hierarchical operations.
expr:	The selection string
as_pattern:	If true, the selection string is treated as a glob pattern. Otherwise the match is exact.
enl:	The per-side enlargement of the box to mark the text (1 gives a 2x2 DBU box)

This special constructor will create a deep region from the text objects delivered by the shape iterator. Each text object will give a small (non-empty) box that represents the text origin. Texts can be selected by their strings - either through a glob pattern or by exact comparison with the given string. The following options are available:

```
region = RBA::Region::new(iter, dss, "*")          # all texts
region = RBA::Region::new(iter, dss, "A*")         # all texts starting with
 an 'A'
region = RBA::Region::new(iter, dss, "A*", false)  # all texts exactly
 matching 'A*'
```

This variant has been introduced in version 0.26.

Python specific notes:
This method is the default initializer of the object.

non_rectangles

Signature: *[const]* Region **non_rectangles**

Description: Returns all polygons which are not rectangles

This method returns all polygons in self which are not rectangles.Merged semantics applies for this method (see merged_semantics= for a description of this concept)

non_rectilinear

Signature: *[const]* Region **non_rectilinear**

Description: Returns all polygons which are not rectilinear

This method returns all polygons in self which are not rectilinear.Merged semantics applies for this method (see merged_semantics= for a description of this concept)

non_squares

Signature: *[const]* Region **non_squares**

Description: Returns all polygons which are not squares

This method returns all polygons in self which are not squares.Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.27.

not

Signature: *[const]* Region **not** (const Region other, PropertyConstraint property_constraint = IgnoreProperties)

Description: Returns the boolean NOT between self and the other region

Returns: The result of the boolean NOT operation

This method will compute the boolean NOT (intersection) between two regions. The result is often but not necessarily always merged. It allows specification of a property constaint - e.g. only performing the boolean operation between shapes with the same user properties.

This variant has been introduced in version 0.28.4.

Python specific notes:
This attribute is available as 'not_' in Python.

not_covering

Signature: *[const]* Region **not_covering** (const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Returns the polygons of this region which are not completely covering polygons from the other region

Returns: A new region containing the polygons which are not covering polygons from the other region

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This attribute is sometimes called 'enclosing' instead of 'covering', but this term is reserved for the respective DRC function.

This method has been introduced in version 0.27.

not_in

Signature: *[const]* Region **not_in** (const Region other)

Description: Returns all polygons which are not members of the other region

This method returns all polygons in self which can not be found in the other region with exactly the same geometry.

not_inside

Signature: *[const]* Region **not_inside** (const Region other)

Description: Returns the polygons of this region which are not completely inside polygons from the other region

Returns: A new region containing the polygons which are not inside polygons from the other region

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

not_interacting

(1) Signature: *[const]* Region **not_interacting** (const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Returns the polygons of this region which do not overlap or touch polygons from the other region

Returns: A new region containing the polygons not overlapping or touching polygons from the other region

'min_count' and 'max_count' impose a constraint on the number of times a polygon of this region has to interact with (different) polygons of the other region to make the polygon not selected. A polygon is not selected by this method if the number of polygons interacting with a polygon of this region is between min_count and max_count (including max_count).

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

The min_count and max_count arguments have been added in version 0.27.

(2) Signature: *[const]* Region **not_interacting** (const Edges other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Returns the polygons of this region which do not overlap or touch edges from the edge collection

Returns: A new region containing the polygons not overlapping or touching edges from the edge collection

'min_count' and 'max_count' impose a constraint on the number of times a polygon of this region has to interact with edges of the edge collection to make the polygon not selected. A polygon is not selected by this method if the number of edges interacting with the polygon is between min_count and max_count (including max_count).

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.25 The min_count and max_count arguments have been added in version 0.27.

(3) Signature: *[const]* Region **not_interacting** (const Texts other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Returns the polygons of this region which do not overlap or touch texts

Returns: A new region containing the polygons not overlapping or touching texts

'min_count' and 'max_count' impose a constraint on the number of times a polygon of this region has to interact with texts of the text collection to make the polygon not selected. A polygon is not selected by this method if the number of texts interacting with the polygon is between min_count and max_count (including max_count).

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.27

not_members_of

Signature: *[const]* Region **not_members_of** (const Region other)

Description: Returns all polygons which are not members of the other region

This method returns all polygons in self which can not be found in the other region with exactly the same geometry.

not_outside

Signature: *[const]* Region **not_outside** (const Region other)

Description: Returns the polygons of this region which are not completely outside polygons from the other region

Returns:	A new region containing the polygons which are not outside polygons from the other region

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

not_overlapping

Signature: *[const]* Region **not_overlapping** (const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Returns the polygons of this region which do not overlap polygons from the other region

Returns:	A new region containing the polygons not overlapping polygons from the other region

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

The count options have been introduced in version 0.27.

not_with

Signature: Region **not_with** (const Region other, PropertyConstraint property_constraint = IgnoreProperties)

Description: Performs the boolean NOT between self and the other region in-place (modifying self)

Returns:	The region after modification (self)

This method will compute the boolean NOT (intersection) between two regions. The result is often but not necessarily always merged. It allows specification of a property constaint - e.g. only performing the boolean operation between shapes with the same user properties.

This variant has been introduced in version 0.28.4.

notch_check

Signature: *[const]* EdgePairs **notch_check** (unsigned int d, bool whole_edges = false, Metrics metrics = Euclidian, variant ignore_angle = default, variant min_projection = 0, variant max_projection = max, bool shielded = true, bool negative = false, PropertyConstraint property_constraint = IgnoreProperties, ZeroDistanceMode zero_distance_mode = IncludeZeroDistanceWhenTouching)

Description: Performs a space check between edges of the same polygon with options

d:	The minimum space for which the polygons are checked
whole_edges:	If true, deliver the whole edges
metrics:	Specify the metrics type
ignore_angle:	The angle above which no check is performed
min_projection:	The lower threshold of the projected length of one edge onto another
max_projection:	The upper limit of the projected length of one edge onto another
shielded:	Enables shielding

negative:	If true, edges not violation the condition will be output as pseudo-edge pairs
property_constraint:	Specifies whether to consider only shapes with a certain property relation
property_constraint:	Only IgnoreProperties and NoPropertyConstraint are allowed - in the last case, properties are copied from the original shapes to the output@param zero_distance_mode Specifies how to handle edges with zero distance

This version is similar to the simple version with one parameter. In addition, it allows to specify many more options.

If "whole_edges" is true, the resulting EdgePairs collection will receive the whole edges which contribute in the space check.

"metrics" can be one of the constants Euclidian, Square or Projection. See there for a description of these constants.

"ignore_angle" specifies the angle limit of two edges. If two edges form an angle equal or above the given value, they will not contribute in the check. Setting this value to 90 (the default) will exclude edges with an angle of 90 degree or more from the check. Use nil for this value to select the default.

"min_projection" and "max_projection" allow selecting edges by their projected value upon each other. It is sufficient if the projection of one edge on the other matches the specified condition. The projected length must be larger or equal to "min_projection" and less than "max_projection". If you don't want to specify one limit, pass nil to the respective value.

"shielded" controls whether shielding is applied. Shielding means that rule violations are not detected 'through' other features. Measurements are only made where the opposite edge is unobstructed. Shielding often is not optional as a rule violation in shielded case automatically comes with rule violations between the original and the shielding features. If not necessary, shielding can be disabled by setting this flag to false. In general, this will improve performance somewhat.

Merged semantics applies for the input of this method (see merged_semantics= for a description of this concept)

The 'shielded' and 'negative' options have been introduced in version 0.27. 'property_constraint' has been added in version 0.28.4. 'zero_distance_mode' has been added in version 0.29.

or

Signature: *[const]* Region **or** (const Region other)

Description: Returns the boolean OR between self and the other region

Returns:	The resulting region

The boolean OR is implemented by merging the polygons of both regions. To simply join the regions without merging, the + operator is more efficient. The 'or' alias has been introduced in version 0.28.12.

Python specific notes:
This attribute is available as 'or_' in Python.

or_with

Signature: Region **or_with** (const Region other)

Description: Performs the boolean OR between self and the other region in-place (modifying self)

Returns:	The region after modification (self)

The boolean OR is implemented by merging the polygons of both regions. To simply join the regions without merging, the + operator is more efficient. Note that in Ruby, the '|=' operator actually does not exist, but is emulated by '|' followed by an assignment. This is less efficient than the in-place operation, so it is recommended to use 'or_with' instead.

The 'or_with' alias has been introduced in version 0.28.12.

outside

Signature: *[const]* Region **outside** (const Region other)

Description: Returns the polygons of this region which are completely outside polygons from the other region

Returns: A new region containing the polygons which are outside polygons from the other region

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

overlap_check

Signature: *[const]* EdgePairs **overlap_check** (const Region other, unsigned int d, bool whole_edges = false, Metrics metrics = Euclidian, variant ignore_angle = default, variant min_projection = 0, variant max_projection = max, bool shielded = true, Region::OppositeFilter opposite_filter = NoOppositeFilter, Region::RectFilter rect_filter = NoRectFilter, bool negative = false, PropertyConstraint property_constraint = IgnoreProperties, ZeroDistanceMode zero_distance_mode = IncludeZeroDistanceWhenTouching)

Description: Performs an overlap check with options

d: The minimum overlap for which the polygons are checked

other: The other region against which to check

whole_edges: If true, deliver the whole edges

metrics: Specify the metrics type

ignore_angle: The angle above which no check is performed

min_projection: The lower threshold of the projected length of one edge onto another

max_projection: The upper limit of the projected length of one edge onto another

opposite_filter: Specifies a filter mode for errors happening on opposite sides of inputs shapes

rect_filter: Specifies an error filter for rectangular input shapes

negative: Negative output from the first input

property_constraint: Specifies whether to consider only shapes with a certain property relation

zero_distance_mode: Specifies how to handle edges with zero distance

If "whole_edges" is true, the resulting EdgePairs collection will receive the whole edges which contribute in the width check.

"metrics" can be one of the constants Euclidian, Square or Projection. See there for a description of these constants.

"ignore_angle" specifies the angle limit of two edges. If two edges form an angle equal or above the given value, they will not contribute in the check. Setting this value to 90 (the default) will exclude edges with an angle of 90 degree or more from the check. Use nil for this value to select the default.

"min_projection" and "max_projection" allow selecting edges by their projected value upon each other. It is sufficient if the projection of one edge on the other matches the specified condition. The projected length must be larger or equal to "min_projection" and less than "max_projection". If you don't want to specify one limit, pass nil to the respective value.

"shielded" controls whether shielding is applied. Shielding means that rule violations are not detected 'through' other features. Measurements are only made where the opposite edge is unobstructed. Shielding often is not optional as a rule violation in shielded case automatically comes with rule violations between the original and the shielding features. If not necessary, shielding can be disabled by setting this flag to false. In general, this will improve performance somewhat.

"opposite_filter" specifies whether to require or reject errors happening on opposite sides of a figure. "rect_filter" allows suppressing specific error configurations on rectangular input figures.

If "negative" is true, only edges from the first input are output as pseudo edge-pairs where the overlap is larger or equal to the limit. This is a way to flag the parts of the first input where the overlap vs. the second input is bigger. Note that only the first input's edges are output. The output is still edge pairs,

but each edge pair contains one edge from the original input and the reverse version of the edge as the second edge.

Merged semantics applies for the input of this method (see merged_semantics= for a description of this concept)

The 'shielded', 'negative', 'not_opposite' and 'rect_sides' options have been introduced in version 0.27. The interpretation of the 'negative' flag has been restriced to first-layout only output in 0.27.1. 'property_constraint' has been added in version 0.28.4. 'zero_distance_mode' has been added in version 0.29.

overlapping

Signature: *[const]* Region **overlapping** (const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Returns the polygons of this region which overlap polygons from the other region

Returns: A new region containing the polygons overlapping polygons from the other region

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

The count options have been introduced in version 0.27.

perimeter

(1) Signature: *[const]* unsigned long **perimeter**

Description: The total perimeter of the polygons

Merged semantics applies for this method (see merged_semantics= for a description of this concept) If merged semantics is not enabled, internal edges are counted as well.

(2) Signature: *[const]* unsigned long **perimeter** (const Box rect)

Description: The total perimeter of the polygons (restricted to a rectangle)

This version will compute the perimeter of the polygons, restricting the computation to the given rectangle. Edges along the border are handled in a special way: they are counted when they are oriented with their inside side toward the rectangle (in other words: outside edges must coincide with the rectangle's border in order to be counted).

Merged semantics applies for this method (see merged_semantics= for a description of this concept) If merged semantics is not enabled, internal edges are counted as well.

process

Signature: void **process** (const PolygonOperator ptr process)

Description: Applies a generic polygon processor in place (replacing the polygons from the Region)

See PolygonProcessor for a description of this feature.

This method has been introduced in version 0.29.

processed

(1) Signature: *[const]* Region **processed** (const PolygonOperator ptr processed)

Description: Applies a generic polygon processor and returns a processed copy

See PolygonProcessor for a description of this feature.

This method has been introduced in version 0.29.

(2) Signature: *[const]* EdgePairs **processed** (const PolygonToEdgePairOperator ptr processed)

Description: Applies a generic polygon-to-edge-pair processor and returns an edge pair collection with the results

See PolygonToEdgePairProcessor for a description of this feature.

This method has been introduced in version 0.29.

(3) Signature: *[const]* Edges **processed** (const PolygonToEdgeOperator ptr processed)

Description: Applies a generic polygon-to-edge processor and returns an edge collection with the results

See PolygonToEdgeProcessor for a description of this feature.

This method has been introduced in version 0.29.

pull_inside

Signature: *[const]* Region **pull_inside** (const Region other)

Description: Returns all polygons of "other" which are inside polygons of this region

Returns: The region after the polygons have been selected (from other)

The "pull_..." methods are similar to "select_..." but work the opposite way: they select shapes from the argument region rather than self. In a deep (hierarchical) context the output region will be hierarchically aligned with self, so the "pull_..." methods provide a way for re-hierarchization.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.26.1

pull_interacting

(1) Signature: *[const]* Region **pull_interacting** (const Region other)

Description: Returns all polygons of "other" which are interacting with (overlapping, touching) polygons of this region

Returns: The region after the polygons have been selected (from other)

See pull_inside for a description of the "pull_..." methods.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.26.1

(2) Signature: *[const]* Edges **pull_interacting** (const Edges other)

Description: Returns all edges of "other" which are interacting with polygons of this region

Returns: The edge collection after the edges have been selected (from other)

See pull_inside for a description of the "pull_..." methods.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.26.1

(3) Signature: *[const]* Texts **pull_interacting** (const Texts other)

Description: Returns all texts of "other" which are interacting with polygons of this region

Returns: The text collection after the texts have been selected (from other)

See pull_inside for a description of the "pull_..." methods.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.27

pull_overlapping

Signature: *[const]* Region **pull_overlapping** (const Region other)

Description: Returns all polygons of "other" which are overlapping polygons of this region

Returns: The region after the polygons have been selected (from other)

See pull_inside for a description of the "pull_..." methods.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.26.1

rasterize

(1) Signature: *[const]* double[][] **rasterize** (const Point origin, const Vector pixel_size, unsigned int nx, unsigned int ny)

Description: A grayscale rasterizer delivering the area covered per pixel

origin:	The lower-left corner of the lowest-left pixel
pixel_size:	The dimension of each pixel (the x component gives the width, the y component the height)
nx:	The number of pixels in horizontal direction
ny:	The number of pixels in vertical direction

The method will create a grayscale, high-resolution density map of a rectangular region. The scan region is defined by the origin, the pixel size and the number of pixels in horizontal (nx) and vertical (ny) direction. The resulting array will contain the area covered by polygons from the region in square database units.

For non-overlapping polygons, the maximum density value is px*py. Overlapping polygons are counted multiple times, so the actual values may be larger. If you want overlaps removed, you have to merge the region before. Merge semantics does not apply for the 'rasterize' method.

The resulting area values are precise within the limits of double-precision floating point arithmetics.

A second version exists that allows specifying an active pixel size which is smaller than the pixel distance hence allowing pixels samples that do not cover the full area, but leave gaps between the pixels.

This method has been added in version 0.29.

(2) Signature: *[const]* double[][] **rasterize** (const Point origin, const Vector pixel_distance, const Vector pixel_size, unsigned int nx, unsigned int ny)

Description: A version of 'rasterize' that allows a pixel step distance which is larger than the pixel size

This version behaves like the first variant of 'rasterize', but the pixel distance (pixel-to-pixel step raster) can be specified separately from the pixel size. Currently, the pixel size must be equal or smaller than the pixel distance - i.e. the pixels must not overlap.

This method has been added in version 0.29.

rectangles

Signature: *[const]* Region **rectangles**

Description: Returns all polygons which are rectangles

This method returns all polygons in self which are rectangles.Merged semantics applies for this method (see merged_semantics= for a description of this concept)

rectilinear

Signature: *[const]* Region **rectilinear**

Description: Returns all polygons which are rectilinear

This method returns all polygons in self which are rectilinear.Merged semantics applies for this method (see merged_semantics= for a description of this concept)

remove_properties

Signature: void **remove_properties**

Description: Removes properties for the given container.

This will remove all properties on the given container.

This method has been introduced in version 0.28.4.

round_corners

Signature: void **round_corners** (double r_inner, double r_outer, unsigned int n)

Description: Corner rounding

r_inner:	Inner corner radius (in database units)

r_outer: Outer corner radius (in database units)

n: The number of points per circle

This method rounds the corners of the polygons in the region. Inner corners will be rounded with a radius of r_inner and outer corners with a radius of r_outer. The circles will be approximated by segments using n segments per full circle.

This method modifies the region. rounded_corners is a method that does the same but returns a new region without modifying self. Merged semantics applies for this method.

rounded_corners

Signature: *[const]* Region **rounded_corners** (double r_inner, double r_outer, unsigned int n)

Description: Corner rounding

r_inner: Inner corner radius (in database units)

r_outer: Outer corner radius (in database units)

n: The number of points per circle

See round_corners for a description of this method. This version returns a new region instead of modifying self (out-of-place).

scale_and_snap

Signature: void **scale_and_snap** (int gx, int mx, int dx, int gy, int my, int dy)

Description: Scales and snaps the region to the given grid

This method will first scale the region by a rational factor of mx/dx horizontally and my/dy vertically and then snap the region to the given grid - each x or y coordinate is brought on the gx or gy grid by rounding to the nearest value which is a multiple of gx or gy.

If gx or gy is 0, the result is brought on a grid of 1.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.26.1.

scaled_and_snapped

Signature: *[const]* Region **scaled_and_snapped** (int gx, int mx, int dx, int gy, int my, int dy)

Description: Returns the scaled and snapped region

This method will scale and snap the region to the given grid and return the scaled and snapped region (see scale_and_snap). The original region is not modified.

This method has been introduced in version 0.26.1.

select_covering

Signature: Region **select_covering** (const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Selects the polygons of this region which are completely covering polygons from the other region

Returns: The region after the polygons have been selected (self)

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This attribute is sometimes called 'enclosing' instead of 'covering', but this term is reserved for the respective DRC function.

This method has been introduced in version 0.27.

select_inside

Signature: Region **select_inside** (const Region other)

Description: Selects the polygons of this region which are completely inside polygons from the other region

Returns: The region after the polygons have been selected (self)

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

select_interacting

(1) Signature: Region **select_interacting** (const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Selects the polygons from this region which overlap or touch polygons from the other region

Returns: The region after the polygons have been selected (self)

'min_count' and 'max_count' impose a constraint on the number of times a polygon of this region has to interact with (different) polygons of the other region to make the polygon selected. A polygon is selected by this method if the number of polygons interacting with a polygon of this region is between min_count and max_count (including max_count).

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

The min_count and max_count arguments have been added in version 0.27.

(2) Signature: Region **select_interacting** (const Edges other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Selects the polygons from this region which overlap or touch edges from the edge collection

Returns: The region after the polygons have been selected (self)

'min_count' and 'max_count' impose a constraint on the number of times a polygon of this region has to interact with edges of the edge collection to make the polygon selected. A polygon is selected by this method if the number of edges interacting with the polygon is between min_count and max_count (including max_count).

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.25 The min_count and max_count arguments have been added in version 0.27.

(3) Signature: Region **select_interacting** (const Texts other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Selects the polygons of this region which overlap or touch texts

Returns: The region after the polygons have been selected (self)

'min_count' and 'max_count' impose a constraint on the number of times a polygon of this region has to interact with texts of the text collection to make the polygon selected. A polygon is selected by this method if the number of texts interacting with the polygon is between min_count and max_count (including max_count).

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.27

select_not_covering

Signature: Region **select_not_covering** (const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Selects the polygons of this region which are not completely covering polygons from the other region

Returns: The region after the polygons have been selected (self)

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This attribute is sometimes called 'enclosing' instead of 'covering', but this term is reserved for the respective DRC function.

This method has been introduced in version 0.27.

select_not_inside

Signature: Region **select_not_inside** (const Region other)

Description: Selects the polygons of this region which are not completely inside polygons from the other region

Returns: The region after the polygons have been selected (self)

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

select_not_interacting

(1) Signature: Region **select_not_interacting** (const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Selects the polygons from this region which do not overlap or touch polygons from the other region

Returns: The region after the polygons have been selected (self)

'min_count' and 'max_count' impose a constraint on the number of times a polygon of this region has to interact with (different) polygons of the other region to make the polygon not selected. A polygon is not selected by this method if the number of polygons interacting with a polygon of this region is between min_count and max_count (including max_count).

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

The min_count and max_count arguments have been added in version 0.27.

(2) Signature: Region **select_not_interacting** (const Edges other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Selects the polygons from this region which do not overlap or touch edges from the edge collection

Returns: The region after the polygons have been selected (self)

'min_count' and 'max_count' impose a constraint on the number of times a polygon of this region has to interact with edges of the edge collection to make the polygon not selected. A polygon is not selected by this method if the number of edges interacting with the polygon is between min_count and max_count (including max_count).

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.25 The min_count and max_count arguments have been added in version 0.27.

(3) Signature: Region **select_not_interacting** (const Texts other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Selects the polygons of this region which do not overlap or touch texts

Returns: The region after the polygons have been selected (self)

'min_count' and 'max_count' impose a constraint on the number of times a polygon of this region has to interact with texts of the text collection to make the polygon not selected. A polygon is not selected by this method if the number of texts interacting with the polygon is between min_count and max_count (including max_count).

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.27

select_not_outside

Signature: Region **select_not_outside** (const Region other)

Description: Selects the polygons of this region which are not completely outside polygons from the other region

Returns: The region after the polygons have been selected (self)

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

select_not_overlapping

Signature: Region **select_not_overlapping** (const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Selects the polygons from this region which do not overlap polygons from the other region

Returns: The region after the polygons have been selected (self)

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

The count options have been introduced in version 0.27.

select_outside

Signature: Region **select_outside** (const Region other)

Description: Selects the polygons of this region which are completely outside polygons from the other region

Returns: The region after the polygons have been selected (self)

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

select_overlapping

Signature: Region **select_overlapping** (const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Selects the polygons from this region which overlap polygons from the other region

Returns: The region after the polygons have been selected (self)

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

The count options have been introduced in version 0.27.

separation_check

Signature: *[const]* EdgePairs **separation_check** (const Region other, unsigned int d, bool whole_edges = false, Metrics metrics = Euclidian, variant ignore_angle = default, variant min_projection = 0, variant max_projection = max, bool shielded = true, Region::OppositeFilter opposite_filter = NoOppositeFilter, Region::RectFilter rect_filter = NoRectFilter, bool negative = false, PropertyConstraint property_constraint = IgnoreProperties, ZeroDistanceMode zero_distance_mode = IncludeZeroDistanceWhenTouching)

Description: Performs a separation check with options

d:	The minimum separation for which the polygons are checked
other:	The other region against which to check
whole_edges:	If true, deliver the whole edges
metrics:	Specify the metrics type
ignore_angle:	The angle above which no check is performed
min_projection:	The lower threshold of the projected length of one edge onto another
max_projection:	The upper limit of the projected length of one edge onto another
opposite_filter:	Specifies a filter mode for errors happening on opposite sides of inputs shapes
rect_filter:	Specifies an error filter for rectangular input shapes
negative:	Negative output from the first input
property_constraint:	Specifies whether to consider only shapes with a certain property relation
zero_distance_mode:	Specifies how to handle edges with zero distance

If "whole_edges" is true, the resulting EdgePairs collection will receive the whole edges which contribute in the width check.

"metrics" can be one of the constants Euclidian, Square or Projection. See there for a description of these constants.

"ignore_angle" specifies the angle limit of two edges. If two edges form an angle equal or above the given value, they will not contribute in the check. Setting this value to 90 (the default) will exclude edges with an angle of 90 degree or more from the check. Use nil for this value to select the default.

"min_projection" and "max_projection" allow selecting edges by their projected value upon each other. It is sufficient if the projection of one edge on the other matches the specified condition. The projected length must be larger or equal to "min_projection" and less than "max_projection". If you don't want to specify one limit, pass nil to the respective value.

"shielded" controls whether shielding is applied. Shielding means that rule violations are not detected 'through' other features. Measurements are only made where the opposite edge is unobstructed. Shielding often is not optional as a rule violation in shielded case automatically comes with rule violations between the original and the shielding features. If not necessary, shielding can be disabled by setting this flag to false. In general, this will improve performance somewhat.

"opposite_filter" specifies whether to require or reject errors happening on opposite sides of a figure. "rect_filter" allows suppressing specific error configurations on rectangular input figures.

If "negative" is true, only edges from the first input are output as pseudo edge-pairs where the separation is larger or equal to the limit. This is a way to flag the parts of the first input where the distance to the second input is bigger. Note that only the first input's edges are output. The output is still edge pairs, but each edge pair contains one edge from the original input and the reverse version of the edge as the second edge.

Merged semantics applies for the input of this method (see merged_semantics= for a description of this concept)

The 'shielded', 'negative', 'not_opposite' and 'rect_sides' options have been introduced in version 0.27. The interpretation of the 'negative' flag has been restriced to first-layout only output in 0.27.1. 'property_constraint' has been added in version 0.28.4. 'zero_distance_mode' has been added in version 0.29.

size

(1) Signature: Region **size** (int dx, int dy, unsigned int mode)

Description: Anisotropic sizing (biasing)

Returns: The region after the sizing has applied (self)

Shifts the contour outwards (dx,dy>0) or inwards (dx,dy<0). dx is the sizing in x-direction and dy is the sizing in y-direction. The sign of dx and dy should be identical.

This method applies a sizing to the region. Before the sizing is done, the region is merged if this is not the case already.

The mode defines at which bending angle cutoff occurs (0:>0, 1:>45, 2:>90, 3:>135, 4:>approx. 168, other:>approx. 179)

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

The result is a set of polygons which may be overlapping, but are not self- intersecting. Polygons may overlap afterwards because they grew big enough to overlap their neighbors. In that case, merge can be used to detect this overlaps by setting the "min_wc" parameter to value 1:

```
r = RBA::Region::new
r.insert(RBA::Box::new(0, 0, 50, 50))
r.insert(RBA::Box::new(100, 0, 150, 50))
r.size(50, 2)
r.merge(false, 1)
# r now is (50,-50;50,100;100,100;100,-50)
```

(2) Signature: Region **size** (const Vector dv, unsigned int mode = 2)

Description: Anisotropic sizing (biasing)

Returns: The region after the sizing has applied (self)

This method is equivalent to "size(dv.x, dv.y, mode)".

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This variant has been introduced in version 0.28.

(3) Signature: Region **size** (int d, unsigned int mode = 2)

Description: Isotropic sizing (biasing)

Returns: The region after the sizing has applied (self)

This method is equivalent to "size(d, d, mode)".

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

(4) Signature: *[const]* unsigned long **size**

Description: Returns the (flat) number of polygons in the region

Use of this method is deprecated. Use count instead

This returns the number of raw polygons (not merged polygons if merged semantics is enabled). The count is computed 'as if flat', i.e. polygons inside a cell are multiplied by the number of times a cell is instantiated.

The 'count' alias has been provided in version 0.26 to avoid ambiguity with the 'size' method which applies a geometrical bias.

Python specific notes:
This method is also available as 'len(object)'.

sized

(1) Signature: *[const]* Region **sized** (int dx, int dy, unsigned int mode)

Description: Returns the anisotropically sized region

Returns: The sized region

This method returns the sized region (see size), but does not modify self.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

(2) Signature: *[const]* Region **sized** (const Vector dv, unsigned int mode = 2)

Description: Returns the (an)isotropically sized region

Returns: The sized region

This method is equivalent to "sized(dv.x, dv.y, mode)". This method returns the sized region (see size), but does not modify self.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This variant has been introduced in version 0.28.

(3) Signature: *[const]* Region **sized** (int d, unsigned int mode = 2)

Description: Returns the isotropically sized region

Returns: The sized region

This method is equivalent to "sized(d, d, mode)". This method returns the sized region (see size), but does not modify self.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

smooth

Signature: void **smooth** (int d, bool keep_hv = false)

Description: Smoothing

d:	The smoothing tolerance (in database units)
keep_hv:	If true, horizontal and vertical edges are maintained

This method will simplify the merged polygons of the region by removing vertexes if the resulting polygon stays equivalent with the original polygon. Equivalence is measured in terms of a deviation which is guaranteed to not become larger than d. This method modifies the region. smoothed is a method that does the same but returns a new region without modifying self. Merged semantics applies for this method.

smoothed

Signature: *[const]* Region **smoothed** (int d, bool keep_hv = false)

Description: Smoothing

d:	The smoothing tolerance (in database units)
keep_hv:	If true, horizontal and vertical edges are maintained

See smooth for a description of this method. This version returns a new region instead of modifying self (out-of-place). It has been introduced in version 0.25.

snap

Signature: void **snap** (int gx, int gy)

Description: Snaps the region to the given grid

This method will snap the region to the given grid - each x or y coordinate is brought on the gx or gy grid by rounding to the nearest value which is a multiple of gx or gy.

If gx or gy is 0, no snapping happens in that direction.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

snapped

Signature: *[const]* Region **snapped** (int gx, int gy)

Description: Returns the snapped region

This method will snap the region to the given grid and return the snapped region (see snap). The original region is not modified.

space_check

Signature: *[const]* EdgePairs **space_check** (unsigned int d, bool whole_edges = false, Metrics metrics = Euclidian, variant ignore_angle = default, variant min_projection = 0, variant max_projection = max, bool shielded = true, Region::OppositeFilter opposite_filter = NoOppositeFilter, Region::RectFilter rect_filter = NoRectFilter, bool negative = false, PropertyConstraint property_constraint = IgnoreProperties, ZeroDistanceMode zero_distance_mode = IncludeZeroDistanceWhenTouching)

Description: Performs a space check with options

d:	The minimum space for which the polygons are checked
whole_edges:	If true, deliver the whole edges
metrics:	Specify the metrics type
ignore_angle:	The angle above which no check is performed
min_projection:	The lower threshold of the projected length of one edge onto another
max_projection:	The upper limit of the projected length of one edge onto another

opposite_filter:	Specifies a filter mode for errors happening on opposite sides of inputs shapes
rect_filter:	Specifies an error filter for rectangular input shapes
negative:	If true, edges not violation the condition will be output as pseudo-edge pairs
property_constraint:	Specifies whether to consider only shapes with a certain property relation
zero_distance_mode:	Specifies how to handle edges with zero distance

If "whole_edges" is true, the resulting EdgePairs collection will receive the whole edges which contribute in the width check.

"metrics" can be one of the constants Euclidian, Square or Projection. See there for a description of these constants.

"ignore_angle" specifies the angle limit of two edges. If two edges form an angle equal or above the given value, they will not contribute in the check. Setting this value to 90 (the default) will exclude edges with an angle of 90 degree or more from the check. Use nil for this value to select the default.

"min_projection" and "max_projection" allow selecting edges by their projected value upon each other. It is sufficient if the projection of one edge on the other matches the specified condition. The projected length must be larger or equal to "min_projection" and less than "max_projection". If you don't want to specify one limit, pass nil to the respective value.

"shielded" controls whether shielding is applied. Shielding means that rule violations are not detected 'through' other features. Measurements are only made where the opposite edge is unobstructed. Shielding often is not optional as a rule violation in shielded case automatically comes with rule violations between the original and the shielding features. If not necessary, shielding can be disabled by setting this flag to false. In general, this will improve performance somewhat.

"opposite_filter" specifies whether to require or reject errors happening on opposite sides of a figure. "rect_filter" allows suppressing specific error configurations on rectangular input figures.

Merged semantics applies for the input of this method (see merged_semantics= for a description of this concept)

The 'shielded', 'negative', 'not_opposite' and 'rect_sides' options have been introduced in version 0.27. 'property_constraint' has been added in version 0.28.4. 'zero_distance_mode' has been added in version 0.29.

split_covering

Signature: *[const]* Region[] **split_covering** (const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Returns the polygons of this region which are completely covering polygons from the other region and the ones which are not at the same time

Returns:	Two new regions: the first containing the result of covering, the second the result of not_covering

This method is equivalent to calling covering and not_covering, but is faster when both results are required. Merged semantics applies for this method (see merged_semantics= for a description of this concept).

This method has been introduced in version 0.27.

split_inside

Signature: *[const]* Region[] **split_inside** (const Region other)

Description: Returns the polygons of this region which are completely inside polygons from the other region and the ones which are not at the same time

Returns:	Two new regions: the first containing the result of inside, the second the result of not_inside

This method is equivalent to calling inside and not_inside, but is faster when both results are required. Merged semantics applies for this method (see merged_semantics= for a description of this concept).

This method has been introduced in version 0.27.

split_interacting

(1) Signature: *[const]* Region[] **split_interacting** (const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Returns the polygons of this region which are interacting with polygons from the other region and the ones which are not at the same time

Returns: Two new regions: the first containing the result of interacting, the second the result of not_interacting

This method is equivalent to calling interacting and not_interacting, but is faster when both results are required. Merged semantics applies for this method (see merged_semantics= for a description of this concept).

This method has been introduced in version 0.27.

(2) Signature: *[const]* Region[] **split_interacting** (const Edges other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Returns the polygons of this region which are interacting with edges from the other edge collection and the ones which are not at the same time

Returns: Two new regions: the first containing the result of interacting, the second the result of not_interacting

This method is equivalent to calling interacting and not_interacting, but is faster when both results are required. Merged semantics applies for this method (see merged_semantics= for a description of this concept).

This method has been introduced in version 0.27.

(3) Signature: *[const]* Region[] **split_interacting** (const Texts other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Returns the polygons of this region which are interacting with texts from the other text collection and the ones which are not at the same time

Returns: Two new regions: the first containing the result of interacting, the second the result of not_interacting

This method is equivalent to calling interacting and not_interacting, but is faster when both results are required. Merged semantics applies for this method (see merged_semantics= for a description of this concept).

This method has been introduced in version 0.27.

split_outside

Signature: *[const]* Region[] **split_outside** (const Region other)

Description: Returns the polygons of this region which are completely outside polygons from the other region and the ones which are not at the same time

Returns: Two new regions: the first containing the result of outside, the second the result of not_outside

This method is equivalent to calling outside and not_outside, but is faster when both results are required. Merged semantics applies for this method (see merged_semantics= for a description of this concept).

This method has been introduced in version 0.27.

split_overlapping

Signature: *[const]* Region[] **split_overlapping** (const Region other, unsigned long min_count = 1, unsigned long max_count = unlimited)

Description: Returns the polygons of this region which are overlapping with polygons from the other region and the ones which are not at the same time

Returns: Two new regions: the first containing the result of overlapping, the second the result of not_overlapping

This method is equivalent to calling overlapping and not_overlapping, but is faster when both results are required. Merged semantics applies for this method (see merged_semantics= for a description of this concept).

This method has been introduced in version 0.27.

squares

Signature: *[const]* Region **squares**

Description: Returns all polygons which are squares

This method returns all polygons in self which are squares.Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.27.

strange_polygon_check

Signature: *[const]* Region **strange_polygon_check**

Description: Returns a region containing those parts of polygons which are "strange"

Strange parts of polygons are self-overlapping parts or non-orientable parts (i.e. in the "8" configuration).

Merged semantics does not apply for this method (see merged_semantics= for a description of this concept)

strict_handling=

Signature: void **strict_handling=** (bool f)

Description: Enables or disables strict handling

Strict handling means to leave away some optimizations. Specifically the output of boolean operations will be merged even if one input is empty. Without strict handling, the operation will be optimized and output won't be merged.

Strict handling is disabled by default and optimization is in place.

This method has been introduced in version 0.23.2.

Python specific notes:
The object exposes a writable attribute 'strict_handling'. This is the setter.

strict_handling?

Signature: *[const]* bool **strict_handling?**

Description: Gets a flag indicating whether merged semantics is enabled

See strict_handling= for a description of this attribute.

This method has been introduced in version 0.23.2.

Python specific notes:
The object exposes a readable attribute 'strict_handling'. This is the getter.

swap

Signature: void **swap** (Region other)

Description: Swap the contents of this region with the contents of another region

This method is useful to avoid excessive memory allocation in some cases. For managed memory languages such as Ruby, those cases will be rare.

to_s

(1) Signature: *[const]* string **to_s**

Description: Converts the region to a string

The length of the output is limited to 20 polygons to avoid giant strings on large regions. For full output use "to_s" with a maximum count parameter.

Python specific notes:
This method is also available as 'str(object)'.

(2) Signature: *[const]* string **to_s** (unsigned long max_count)

Description: Converts the region to a string

This version allows specification of the maximum number of polygons contained in the string.

transform

(1) Signature: Region **transform** (const Trans t)

Description: Transform the region (modifies self)

t: The transformation to apply.

Returns: The transformed region.

Transforms the region with the given transformation. This version modifies the region and returns a reference to self.

(2) Signature: Region **transform** (const ICplxTrans t)

Description: Transform the region with a complex transformation (modifies self)

t: The transformation to apply.

Returns: The transformed region.

Transforms the region with the given transformation. This version modifies the region and returns a reference to self.

(3) Signature: Region **transform** (const IMatrix2d t)

Description: Transform the region (modifies self)

t: The transformation to apply.

Returns: The transformed region.

Transforms the region with the given 2d matrix transformation. This version modifies the region and returns a reference to self.

This variant was introduced in version 0.27.

(4) Signature: Region **transform** (const IMatrix3d t)

Description: Transform the region (modifies self)

t: The transformation to apply.

Returns: The transformed region.

Transforms the region with the given 3d matrix transformation. This version modifies the region and returns a reference to self.

This variant was introduced in version 0.27.

transform_icplx

Signature: Region **transform_icplx** (const ICplxTrans t)

Description: Transform the region with a complex transformation (modifies self)

t: The transformation to apply.

Returns: The transformed region.

Use of this method is deprecated. Use transform instead

Transforms the region with the given transformation. This version modifies the region and returns a reference to self.

transformed

(1) Signature: *[const]* Region **transformed** (const Trans t)

Description: Transforms the region

t: The transformation to apply.

Returns: The transformed region.

Transforms the region with the given transformation. Does not modify the region but returns the transformed region.

(2) Signature: *[const]* Region **transformed** (const ICplxTrans t)

Description: Transforms the region with a complex transformation

t: The transformation to apply.

Returns: The transformed region.

Transforms the region with the given complex transformation. Does not modify the region but returns the transformed region.

(3) Signature: *[const]* Region **transformed** (const IMatrix2d t)

Description: Transforms the region

t: The transformation to apply.

Returns: The transformed region.

Transforms the region with the given 2d matrix transformation. Does not modify the region but returns the transformed region.

This variant was introduced in version 0.27.

(4) Signature: *[const]* Region **transformed** (const IMatrix3d t)

Description: Transforms the region

t: The transformation to apply.

Returns: The transformed region.

Transforms the region with the given 3d matrix transformation. Does not modify the region but returns the transformed region.

This variant was introduced in version 0.27.

transformed_icplx

Signature: *[const]* Region **transformed_icplx** (const ICplxTrans t)

Description: Transforms the region with a complex transformation

t: The transformation to apply.

Returns: The transformed region.

Use of this method is deprecated. Use transformed instead

Transforms the region with the given complex transformation. Does not modify the region but returns the transformed region.

width_check

Signature: *[const]* EdgePairs **width_check** (unsigned int d, bool whole_edges = false, Metrics metrics = Euclidian, variant ignore_angle = default, variant min_projection = 0, variant max_projection = max, bool shielded = true, bool negative = false, PropertyConstraint property_constraint = IgnoreProperties, ZeroDistanceMode zero_distance_mode = IncludeZeroDistanceWhenTouching)

Description: Performs a width check with options

d:	The minimum width for which the polygons are checked
whole_edges:	If true, deliver the whole edges
metrics:	Specify the metrics type
ignore_angle:	The angle above which no check is performed
min_projection:	The lower threshold of the projected length of one edge onto another
max_projection:	The upper limit of the projected length of one edge onto another
shielded:	Enables shielding
negative:	If true, edges not violation the condition will be output as pseudo-edge pairs
property_constraint:	Only IgnoreProperties and NoPropertyConstraint are allowed - in the last case, properties are copied from the original shapes to the output. @param zero_distance_mode Specifies how to handle edges with zero distance

Other than 'width' allow more options here.

This version is similar to the simple version with one parameter. In addition, it allows to specify many more options.

If "whole_edges" is true, the resulting EdgePairs collection will receive the whole edges which contribute in the width check.

"metrics" can be one of the constants Euclidian, Square or Projection. See there for a description of these constants.

"ignore_angle" specifies the angle limit of two edges. If two edges form an angle equal or above the given value, they will not contribute in the check. Setting this value to 90 (the default) will exclude edges with an angle of 90 degree or more from the check. Use nil for this value to select the default.

"min_projection" and "max_projection" allow selecting edges by their projected value upon each other. It is sufficient if the projection of one edge on the other matches the specified condition. The projected length must be larger or equal to "min_projection" and less than "max_projection". If you don't want to specify one limit, pass nil to the respective value.

"shielded" controls whether shielding is applied. Shielding means that rule violations are not detected 'through' other features. Measurements are only made where the opposite edge is unobstructed. Shielding often is not optional as a rule violation in shielded case automatically comes with rule violations between the original and the shielding features. If not necessary, shielding can be disabled by setting this flag to false. In general, this will improve performance somewhat.

Merged semantics applies for the input of this method (see merged_semantics= for a description of this concept)

The 'shielded' and 'negative' options have been introduced in version 0.27. 'property_constraint' has been added in version 0.28.4. 'zero_distance_mode' has been added in version 0.28.16.

with_angle

(1) Signature: *[const]* EdgePairs **with_angle** (double angle, bool inverse)

Description: Returns markers on every corner with the given angle (or not with the given angle)

If the inverse flag is false, this method returns an error marker (an EdgePair object) for every corner whose connected edges form an angle with the given value (in degree). If the inverse flag is true, the method returns markers for every corner whose angle is not the given value.

The edge pair objects returned will contain both edges forming the angle.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

(2) Signature: *[const]* EdgePairs **with_angle** (double amin, double amax, bool inverse)

Description: Returns markers on every corner with an angle of more than amin and less than amax (or the opposite)

If the inverse flag is false, this method returns an error marker (an EdgePair object) for every corner whose connected edges form an angle whose value is more or equal to amin (in degree) or less (but not equal to) amax. If the inverse flag is true, the method returns markers for every corner whose angle is not matching that criterion.

The edge pair objects returned will contain both edges forming the angle.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

with_area

(1) Signature: *[const]* Region **with_area** (long area, bool inverse)

Description: Filter the polygons by area

Filters the polygons of the region by area. If "inverse" is false, only polygons which have the given area are returned. If "inverse" is true, polygons not having the given area are returned.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

(2) Signature: *[const]* Region **with_area** (variant min_area, variant max_area, bool inverse)

Description: Filter the polygons by area

Filters the polygons of the region by area. If "inverse" is false, only polygons which have an area larger or equal to "min_area" and less than "max_area" are returned. If "inverse" is true, polygons having an area less than "min_area" or larger or equal than "max_area" are returned.

If you don't want to specify a lower or upper limit, pass nil to that parameter.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

with_area_ratio

(1) Signature: *[const]* Region **with_area_ratio** (double ratio, bool inverse)

Description: Filters the polygons by the bounding box area to polygon area ratio

The area ratio is defined by the ratio of bounding box area to polygon area. It's a measure how much the bounding box is approximating the polygon. 'Thin polygons' have a large area ratio, boxes has an area ratio of 1. The area ratio is always larger or equal to 1. With 'inverse' set to false, this version filters polygons which have an area ratio equal to the given value. With 'inverse' set to true, all other polygons will be returned.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.27.

(2) Signature: *[const]* Region **with_area_ratio** (variant min_ratio, variant max_ratio, bool inverse, bool min_included = true, bool max_included = true)

Description: Filters the polygons by the aspect ratio of their bounding boxes

The area ratio is defined by the ratio of bounding box area to polygon area. It's a measure how much the bounding box is approximating the polygon. 'Thin polygons' have a large area ratio, boxes has an area ratio of 1. The area ratio is always larger or equal to 1. With 'inverse' set to false, this version filters polygons which have an area ratio between 'min_ratio' and 'max_ratio'. With 'min_included' set to true, the 'min_ratio' value is included in the range, otherwise it's excluded. Same for 'max_included' and 'max_ratio'. With 'inverse' set to true, all other polygons will be returned.

If you don't want to specify a lower or upper limit, pass nil to that parameter.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.27.

with_bbox_aspect_ratio

(1) Signature: *[const]* Region **with_bbox_aspect_ratio** (double ratio, bool inverse)

Description: Filters the polygons by the aspect ratio of their bounding boxes

Filters the polygons of the region by the aspect ratio of their bounding boxes. The aspect ratio is the ratio of larger to smaller dimension of the bounding box. A square has an aspect ratio of 1.

With 'inverse' set to false, this version filters polygons which have a bounding box aspect ratio equal to the given value. With 'inverse' set to true, all other polygons will be returned.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.27.

(2) Signature: *[const]* Region **with_bbox_aspect_ratio** (variant min_ratio, variant max_ratio, bool inverse, bool min_included = true, bool max_included = true)

Description: Filters the polygons by the aspect ratio of their bounding boxes

Filters the polygons of the region by the aspect ratio of their bounding boxes. The aspect ratio is the ratio of larger to smaller dimension of the bounding box. A square has an aspect ratio of 1.

With 'inverse' set to false, this version filters polygons which have a bounding box aspect ratio between 'min_ratio' and 'max_ratio'. With 'min_included' set to true, the 'min_ratio' value is included in the range, otherwise it's excluded. Same for 'max_included' and 'max_ratio'. With 'inverse' set to true, all other polygons will be returned.

If you don't want to specify a lower or upper limit, pass nil to that parameter.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.27.

with_bbox_height

(1) Signature: *[const]* Region **with_bbox_height** (unsigned int height, bool inverse)

Description: Filter the polygons by bounding box height

Filters the polygons of the region by the height of their bounding box. If "inverse" is false, only polygons whose bounding box has the given height are returned. If "inverse" is true, polygons whose bounding box does not have the given height are returned.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

(2) Signature: *[const]* Region **with_bbox_height** (variant min_height, variant max_height, bool inverse)

Description: Filter the polygons by bounding box height

Filters the polygons of the region by the height of their bounding box. If "inverse" is false, only polygons whose bounding box has a height larger or equal to "min_height" and less than "max_height" are returned. If "inverse" is true, all polygons not matching this criterion are returned. If you don't want to specify a lower or upper limit, pass nil to that parameter.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

with_bbox_max

(1) Signature: *[const]* Region **with_bbox_max** (unsigned int dim, bool inverse)

Description: Filter the polygons by bounding box width or height, whichever is larger

Filters the polygons of the region by the maximum dimension of their bounding box. If "inverse" is false, only polygons whose bounding box's larger dimension is equal to the given value are returned. If "inverse" is true, all polygons not matching this criterion are returned. Merged semantics applies for this method (see merged_semantics= for a description of this concept)

(2) Signature: *[const]* Region **with_bbox_max** (variant min_dim, variant max_dim, bool inverse)

Description: Filter the polygons by bounding box width or height, whichever is larger

Filters the polygons of the region by the minimum dimension of their bounding box. If "inverse" is false, only polygons whose bounding box's larger dimension is larger or equal to "min_dim" and less than "max_dim" are returned. If "inverse" is true, all polygons not matching this criterion are returned. If you don't want to specify a lower or upper limit, pass nil to that parameter.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

with_bbox_min

(1) Signature: *[const]* Region **with_bbox_min** (unsigned int dim, bool inverse)

Description: Filter the polygons by bounding box width or height, whichever is smaller

Filters the polygons inside the region by the minimum dimension of their bounding box. If "inverse" is false, only polygons whose bounding box's smaller dimension is equal to the given value are returned. If "inverse" is true, all polygons not matching this criterion are returned. Merged semantics applies for this method (see merged_semantics= for a description of this concept)

(2) Signature: *[const]* Region **with_bbox_min** (variant min_dim, variant max_dim, bool inverse)

Description: Filter the polygons by bounding box width or height, whichever is smaller

Filters the polygons of the region by the minimum dimension of their bounding box. If "inverse" is false, only polygons whose bounding box's smaller dimension is larger or equal to "min_dim" and less than "max_dim" are returned. If "inverse" is true, all polygons not matching this criterion are returned. If you don't want to specify a lower or upper limit, pass nil to that parameter.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

with_bbox_width

(1) Signature: *[const]* Region **with_bbox_width** (unsigned int width, bool inverse)

Description: Filter the polygons by bounding box width

Filters the polygons of the region by the width of their bounding box. If "inverse" is false, only polygons whose bounding box has the given width are returned. If "inverse" is true, polygons whose bounding box does not have the given width are returned.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

(2) Signature: *[const]* Region **with_bbox_width** (variant min_width, variant max_width, bool inverse)

Description: Filter the polygons by bounding box width

Filters the polygons of the region by the width of their bounding box. If "inverse" is false, only polygons whose bounding box has a width larger or equal to "min_width" and less than "max_width" are returned. If "inverse" is true, all polygons not matching this criterion are returned. If you don't want to specify a lower or upper limit, pass nil to that parameter.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

with_holes

(1) Signature: *[const]* Region **with_holes** (unsigned long nholes, bool inverse)

Description: Filters the polygons by their number of holes

Filters the polygons of the region by number of holes. If "inverse" is false, only polygons which have the given number of holes are returned. If "inverse" is true, polygons not having the given of holes are returned.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.27.

(2) Signature: *[const]* Region **with_holes** (variant min_bholes, variant max_nholes, bool inverse)

Description: Filter the polygons by their number of holes

Filters the polygons of the region by number of holes. If "inverse" is false, only polygons which have a hole count larger or equal to "min_nholes" and less than "max_nholes" are returned. If "inverse" is true, polygons having a hole count less than "min_nholes" or larger or equal than "max_nholes" are returned.

If you don't want to specify a lower or upper limit, pass nil to that parameter.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.27.

with_perimeter

(1) Signature: *[const]* Region **with_perimeter** (unsigned long perimeter, bool inverse)

Description: Filter the polygons by perimeter

Filters the polygons of the region by perimeter. If "inverse" is false, only polygons which have the given perimeter are returned. If "inverse" is true, polygons not having the given perimeter are returned.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

(2) Signature: *[const]* Region **with_perimeter** (variant min_perimeter, variant max_perimeter, bool inverse)

Description: Filter the polygons by perimeter

Filters the polygons of the region by perimeter. If "inverse" is false, only polygons which have a perimeter larger or equal to "min_perimeter" and less than "max_perimeter" are returned. If "inverse" is true, polygons having a perimeter less than "min_perimeter" or larger or equal than "max_perimeter" are returned.

If you don't want to specify a lower or upper limit, pass nil to that parameter.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

with_relative_height

(1) Signature: *[const]* Region **with_relative_height** (double ratio, bool inverse)

Description: Filters the polygons by the ratio of height to width

This method filters the polygons of the region by the ratio of height vs. width of their bounding boxes. 'Tall' polygons have a large value while 'flat' polygons have a small value. A square has a relative height of 1.

An alternative method is 'with_area_ratio' which can be more efficient because it's isotropic.

With 'inverse' set to false, this version filters polygons which have a relative height equal to the given value. With 'inverse' set to true, all other polygons will be returned.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.27.

(2) Signature: *[const]* Region **with_relative_height** (variant min_ratio, variant max_ratio, bool inverse, bool min_included = true, bool max_included = true)

Description: Filters the polygons by the bounding box height to width ratio

This method filters the polygons of the region by the ratio of height vs. width of their bounding boxes. 'Tall' polygons have a large value while 'flat' polygons have a small value. A square has a relative height of 1.

An alternative method is 'with_area_ratio' which can be more efficient because it's isotropic.

With 'inverse' set to false, this version filters polygons which have a relative height between 'min_ratio' and 'max_ratio'. With 'min_included' set to true, the 'min_ratio' value is included in the range, otherwise it's excluded. Same for 'max_included' and 'max_ratio'. With 'inverse' set to true, all other polygons will be returned.

If you don't want to specify a lower or upper limit, pass nil to that parameter.

Merged semantics applies for this method (see merged_semantics= for a description of this concept)

This method has been introduced in version 0.27.

write

Signature: *[const]* void **write** (string filename)

Description: Writes the region to a file

This method is provided for debugging purposes. It writes the object to a flat layer 0/0 in a single top cell.

This method has been introduced in version 0.29.

xor

Signature: *[const]* Region **xor** (const Region other)

Description: Returns the boolean XOR between self and the other region

Returns: The result of the boolean XOR operation

This method will compute the boolean XOR (intersection) between two regions. The result is often but not necessarily always merged.

The 'xor' alias has been introduced in version 0.28.12.

xor_with

Signature: Region **xor_with** (const Region other)

Description: Performs the boolean XOR between self and the other region in-place (modifying self)

Returns: The region after modification (self)

This method will compute the boolean XOR (intersection) between two regions. The result is often but not necessarily always merged.

Note that in Ruby, the '^=' operator actually does not exist, but is emulated by '^' followed by an assignment. This is less efficient than the in-place operation, so it is recommended to use 'xor_with' instead.

The 'xor_with' alias has been introduced in version 0.28.12.

|

Signature: *[const]* Region **|** (const Region other)

Description: Returns the boolean OR between self and the other region

Returns: The resulting region

The boolean OR is implemented by merging the polygons of both regions. To simply join the regions without merging, the + operator is more efficient. The 'or' alias has been introduced in version 0.28.12.

Python specific notes:
This attribute is available as 'or_' in Python.

|=

Signature: Region **|=** (const Region other)

Description: Performs the boolean OR between self and the other region in-place (modifying self)

Returns: The region after modification (self)

The boolean OR is implemented by merging the polygons of both regions. To simply join the regions without merging, the + operator is more efficient. Note that in Ruby, the '|=' operator actually does not exist, but is emulated by '|' followed by an assignment. This is less efficient than the in-place operation, so it is recommended to use 'or_with' instead.

The 'or_with' alias has been introduced in version 0.28.12.

4.88. API reference - Class Region::RectFilter

Notation used in Ruby API documentation

Module: db

Description: This class represents the error filter mode on rectangles for \Region#separation and related checks.

This class is equivalent to the class Region::RectFilter

This enum has been introduced in version 0.27.

Public constructors

new Region::RectFilter ptr	**new**	(int i)	Creates an enum from an integer value
new Region::RectFilter ptr	**new**	(string s)	Creates an enum from a string value

Public methods

[const]	bool	**!=**	(const Region::RectFilter other)	Compares two enums for inequality
[const]	bool	**!=**	(int other)	Compares an enum with an integer for inequality
[const]	bool	**<**	(const Region::RectFilter other)	Returns true if the first enum is less (in the enum symbol order) than the second
[const]	bool	**<**	(int other)	Returns true if the enum is less (in the enum symbol order) than the integer value
[const]	bool	**==**	(const Region::RectFilter other)	Compares two enums
[const]	bool	**==**	(int other)	Compares an enum with an integer value
[const]	int	**hash**		Gets the hash value from the enum
[const]	string	**inspect**		Converts an enum to a visual string
[const]	int	**to_i**		Gets the integer value from the enum
[const]	string	**to_s**		Gets the symbolic string from an enum

Public static methods and constants

[static,const]	Region::RectFilter	**FourSidesAllowed**	Allow errors when on all sides
[static,const]	Region::RectFilter	**NoRectFilter**	Specifies no filtering
[static,const]	Region::RectFilter	**OneSideAllowed**	Allow errors on one side
[static,const]	Region::RectFilter	**ThreeSidesAllowed**	Allow errors when on three sides

[static,const]	Region::RectFilter	**TwoConnectedSidesAllow**	Allow errors on two sides ("L" configuration)
[static,const]	Region::RectFilter	**TwoOppositeSidesAllowed**	Allow errors on two opposite sides
[static,const]	Region::RectFilter	**TwoSidesAllowed**	Allow errors on two sides (not specified which)

Detailed description

!=	**(1) Signature**: *[const]* bool **!=** (const Region::RectFilter other) **Description**: Compares two enums for inequality **(2) Signature**: *[const]* bool **!=** (int other) **Description**: Compares an enum with an integer for inequality
<	**(1) Signature**: *[const]* bool **<** (const Region::RectFilter other) **Description**: Returns true if the first enum is less (in the enum symbol order) than the second **(2) Signature**: *[const]* bool **<** (int other) **Description**: Returns true if the enum is less (in the enum symbol order) than the integer value
==	**(1) Signature**: *[const]* bool **==** (const Region::RectFilter other) **Description**: Compares two enums **(2) Signature**: *[const]* bool **==** (int other) **Description**: Compares an enum with an integer value
FourSidesAllowed	**Signature**: *[static,const]* Region::RectFilter **FourSidesAllowed** **Description**: Allow errors when on all sides **Python specific notes:** The object exposes a readable attribute 'FourSidesAllowed'. This is the getter.
NoRectFilter	**Signature**: *[static,const]* Region::RectFilter **NoRectFilter** **Description**: Specifies no filtering **Python specific notes:** The object exposes a readable attribute 'NoRectFilter'. This is the getter.
OneSideAllowed	**Signature**: *[static,const]* Region::RectFilter **OneSideAllowed** **Description**: Allow errors on one side **Python specific notes:** The object exposes a readable attribute 'OneSideAllowed'. This is the getter.
ThreeSidesAllowed	**Signature**: *[static,const]* Region::RectFilter **ThreeSidesAllowed** **Description**: Allow errors when on three sides **Python specific notes:**

	The object exposes a readable attribute 'ThreeSidesAllowed'. This is the getter.
TwoConnectedSidesAllowed	**Signature**: *[static,const]* Region::RectFilter **TwoConnectedSidesAllowed** **Description**: Allow errors on two sides ("L" configuration) **Python specific notes:** The object exposes a readable attribute 'TwoConnectedSidesAllowed'. This is the getter.
TwoOppositeSidesAllowed	**Signature**: *[static,const]* Region::RectFilter **TwoOppositeSidesAllowed** **Description**: Allow errors on two opposite sides **Python specific notes:** The object exposes a readable attribute 'TwoOppositeSidesAllowed'. This is the getter.
TwoSidesAllowed	**Signature**: *[static,const]* Region::RectFilter **TwoSidesAllowed** **Description**: Allow errors on two sides (not specified which) **Python specific notes:** The object exposes a readable attribute 'TwoSidesAllowed'. This is the getter.
hash	**Signature**: *[const]* int **hash** **Description**: Gets the hash value from the enum **Python specific notes:** This method is also available as 'hash(object)'.
inspect	**Signature**: *[const]* string **inspect** **Description**: Converts an enum to a visual string **Python specific notes:** This method is also available as 'repr(object)'.
new	**(1) Signature**: *[static]* new Region::RectFilter ptr **new** (int i) **Description**: Creates an enum from an integer value **Python specific notes:** This method is the default initializer of the object. **(2) Signature**: *[static]* new Region::RectFilter ptr **new** (string s) **Description**: Creates an enum from a string value **Python specific notes:** This method is the default initializer of the object.
to_i	**Signature**: *[const]* int **to_i** **Description**: Gets the integer value from the enum **Python specific notes:** This method is also available as 'int(object)'.
to_s	**Signature**: *[const]* string **to_s** **Description**: Gets the symbolic string from an enum **Python specific notes:** This method is also available as 'str(object)'.

4.89. API reference - Class Region::OppositeFilter

Notation used in Ruby API documentation

Module: db

Description: This class represents the opposite error filter mode for \Region#separation and related checks.

This class is equivalent to the class Region::OppositeFilter

This enum has been introduced in version 0.27.

Public constructors

new Region::OppositeFilter ptr	**new**	(int i)	Creates an enum from an integer value
new Region::OppositeFilter ptr	**new**	(string s)	Creates an enum from a string value

Public methods

[const]	bool	**!=**	(const Region::OppositeFilter other)	Compares two enums for inequality
[const]	bool	**!=**	(int other)	Compares an enum with an integer for inequality
[const]	bool	**<**	(const Region::OppositeFilter other)	Returns true if the first enum is less (in the enum symbol order) than the second
[const]	bool	**<**	(int other)	Returns true if the enum is less (in the enum symbol order) than the integer value
[const]	bool	**==**	(const Region::OppositeFilter other)	Compares two enums
[const]	bool	**==**	(int other)	Compares an enum with an integer value
[const]	int	**hash**		Gets the hash value from the enum
[const]	string	**inspect**		Converts an enum to a visual string
[const]	int	**to_i**		Gets the integer value from the enum
[const]	string	**to_s**		Gets the symbolic string from an enum

Public static methods and constants

[static,const]	Region::OppositeFilter	**NoOppositeFilter**	No opposite filtering
[static,const]	Region::OppositeFilter	**NotOpposite**	Only errors NOT appearing on opposite sides of a figure will be reported
[static,const]	Region::OppositeFilter	**OnlyOpposite**	Only errors appearing on opposite sides of a figure will be reported

Detailed description

!=	**(1) Signature**: *[const]* bool **!=** (const Region::OppositeFilter other) **Description**: Compares two enums for inequality **(2) Signature**: *[const]* bool **!=** (int other) **Description**: Compares an enum with an integer for inequality
<	**(1) Signature**: *[const]* bool **<** (const Region::OppositeFilter other) **Description**: Returns true if the first enum is less (in the enum symbol order) than the second **(2) Signature**: *[const]* bool **<** (int other) **Description**: Returns true if the enum is less (in the enum symbol order) than the integer value
==	**(1) Signature**: *[const]* bool **==** (const Region::OppositeFilter other) **Description**: Compares two enums **(2) Signature**: *[const]* bool **==** (int other) **Description**: Compares an enum with an integer value
NoOppositeFilter	**Signature**: *[static,const]* Region::OppositeFilter **NoOppositeFilter** **Description**: No opposite filtering **Python specific notes:** The object exposes a readable attribute 'NoOppositeFilter'. This is the getter.
NotOpposite	**Signature**: *[static,const]* Region::OppositeFilter **NotOpposite** **Description**: Only errors NOT appearing on opposite sides of a figure will be reported **Python specific notes:** The object exposes a readable attribute 'NotOpposite'. This is the getter.
OnlyOpposite	**Signature**: *[static,const]* Region::OppositeFilter **OnlyOpposite** **Description**: Only errors appearing on opposite sides of a figure will be reported **Python specific notes:** The object exposes a readable attribute 'OnlyOpposite'. This is the getter.
hash	**Signature**: *[const]* int **hash** **Description**: Gets the hash value from the enum **Python specific notes:** This method is also available as 'hash(object)'.
inspect	**Signature**: *[const]* string **inspect** **Description**: Converts an enum to a visual string **Python specific notes:** This method is also available as 'repr(object)'.

new

(1) Signature: *[static]* new Region::OppositeFilter ptr **new** (int i)

Description: Creates an enum from an integer value

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new Region::OppositeFilter ptr **new** (string s)

Description: Creates an enum from a string value

Python specific notes:
This method is the default initializer of the object.

to_i

Signature: *[const]* int **to_i**

Description: Gets the integer value from the enum

Python specific notes:
This method is also available as 'int(object)'.

to_s

Signature: *[const]* string **to_s**

Description: Gets the symbolic string from an enum

Python specific notes:
This method is also available as 'str(object)'.

4.90. API reference - Class Metrics

Notation used in Ruby API documentation

Module: db

Description: This class represents the metrics type for \Region#width and related checks.

This enum has been introduced in version 0.27.

Public constructors

new Metrics ptr	**new**	(int i)		Creates an enum from an integer value
new Metrics ptr	**new**	(string s)		Creates an enum from a string value

Public methods

[const]	bool	**!=**	(const Metrics other)	Compares two enums for inequality
[const]	bool	**!=**	(int other)	Compares an enum with an integer for inequality
[const]	bool	**<**	(const Metrics other)	Returns true if the first enum is less (in the enum symbol order) than the second
[const]	bool	**<**	(int other)	Returns true if the enum is less (in the enum symbol order) than the integer value
[const]	bool	**==**	(const Metrics other)	Compares two enums
[const]	bool	**==**	(int other)	Compares an enum with an integer value
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const Metrics other)	Assigns another object to self
[const]	new Metrics ptr	**dup**		Creates a copy of self
[const]	int	**hash**		Gets the hash value from the enum
[const]	string	**inspect**		Converts an enum to a visual string

[const]	int	**to_i**	Gets the integer value from the enum
[const]	string	**to_s**	Gets the symbolic string from an enum

Public static methods and constants

[static,const]	Metrics	**Euclidian**	Specifies Euclidian metrics for the check functions
[static,const]	Metrics	**Projection**	Specifies projected distance metrics for the check functions
[static,const]	Metrics	**Square**	Specifies square metrics for the check functions

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

!=

(1) Signature: *[const]* bool **!=** (const Metrics other)
Description: Compares two enums for inequality

(2) Signature: *[const]* bool **!=** (int other)
Description: Compares an enum with an integer for inequality

<

(1) Signature: *[const]* bool **<** (const Metrics other)
Description: Returns true if the first enum is less (in the enum symbol order) than the second

(2) Signature: *[const]* bool **<** (int other)
Description: Returns true if the enum is less (in the enum symbol order) than the integer value

==

(1) Signature: *[const]* bool **==** (const Metrics other)
Description: Compares two enums

(2) Signature: *[const]* bool **==** (int other)
Description: Compares an enum with an integer value

Euclidian

Signature: *[static,const]* Metrics **Euclidian**
Description: Specifies Euclidian metrics for the check functions

This value can be used for the metrics parameter in the check functions, i.e. width_check. This value specifies Euclidian metrics, i.e. the distance between two points is measured by:

```
d = sqrt(dx^2 + dy^2)
```

All points within a circle with radius d around one point are considered to have a smaller distance than d.

Python specific notes:
The object exposes a readable attribute 'Euclidian'. This is the getter.

Projection

Signature: *[static,const]* Metrics **Projection**

Description: Specifies projected distance metrics for the check functions

This value can be used for the metrics parameter in the check functions, i.e. width_check. This value specifies projected metrics, i.e. the distance is defined as the minimum distance measured perpendicular to one edge. That implies that the distance is defined only where two edges have a non-vanishing projection onto each other.

Python specific notes:
The object exposes a readable attribute 'Projection'. This is the getter.

Square

Signature: *[static,const]* Metrics **Square**

Description: Specifies square metrics for the check functions

This value can be used for the metrics parameter in the check functions, i.e. width_check. This value specifies square metrics, i.e. the distance between two points is measured by:

```
d = max(abs(dx), abs(dy))
```

All points within a square with length 2*d around one point are considered to have a smaller distance than d in this metrics.

Python specific notes:
The object exposes a readable attribute 'Square'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const Metrics other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new Metrics ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

hash

Signature: *[const]* int **hash**

Description: Gets the hash value from the enum

Python specific notes:
This method is also available as 'hash(object)'.

inspect

Signature: *[const]* string **inspect**

Description: Converts an enum to a visual string

Python specific notes:
This method is also available as 'repr(object)'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

(1) Signature: *[static]* new Metrics ptr **new** (int i)

Description: Creates an enum from an integer value

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new Metrics ptr **new** (string s)

Description: Creates an enum from a string value

Python specific notes:
This method is the default initializer of the object.

to_i

Signature: *[const]* int **to_i**

Description: Gets the integer value from the enum

Python specific notes:
This method is also available as 'int(object)'.

to_s

Signature: *[const]* string **to_s**

Description: Gets the symbolic string from an enum

Python specific notes:
This method is also available as 'str(object)'.

4.91. API reference - Class EdgeMode

Notation used in Ruby API documentation

Module: db

Description: This class represents the edge mode type for \Region#edges.

This enum has been introduced in version 0.29.

Public constructors

new EdgeMode ptr	**new**	(int i)	Creates an enum from an integer value
new EdgeMode ptr	**new**	(string s)	Creates an enum from a string value

Public methods

[const]	bool	**!=**	(const EdgeMode other)	Compares two enums for inequality
[const]	bool	**!=**	(int other)	Compares an enum with an integer for inequality
[const]	bool	**<**	(const EdgeMode other)	Returns true if the first enum is less (in the enum symbol order) than the second
[const]	bool	**<**	(int other)	Returns true if the enum is less (in the enum symbol order) than the integer value
[const]	bool	**==**	(const EdgeMode other)	Compares two enums
[const]	bool	**==**	(int other)	Compares an enum with an integer value
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const EdgeMode other)	Assigns another object to self
[const]	new EdgeMode ptr	**dup**		Creates a copy of self

[const]	int	**hash**	Gets the hash value from the enum
[const]	string	**inspect**	Converts an enum to a visual string
[const]	int	**to_i**	Gets the integer value from the enum
[const]	string	**to_s**	Gets the symbolic string from an enum

Public static methods and constants

[static,const]	EdgeMode	**All**	Selects all edges
[static,const]	EdgeMode	**Concave**	Selects only concave edges
[static,const]	EdgeMode	**Convex**	Selects only convex edges
[static,const]	EdgeMode	**NotConcave**	Selects only edges which are not concave
[static,const]	EdgeMode	**NotConvex**	Selects only edges which are not convex
[static,const]	EdgeMode	**NotStep**	Selects only edges which are not steps
[static,const]	EdgeMode	**NotStepIn**	Selects only edges which are not steps leading inside
[static,const]	EdgeMode	**NotStepOut**	Selects only edges which are not steps leading outside
[static,const]	EdgeMode	**Step**	Selects only step edges leading inside or outside
[static,const]	EdgeMode	**StepIn**	Selects only step edges leading inside
[static,const]	EdgeMode	**StepOut**	Selects only step edges leading outside

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

!=

(1) Signature: *[const]* bool **!=** (const EdgeMode other)
Description: Compares two enums for inequality

(2) Signature: *[const]* bool **!=** (int other)

	Description: Compares an enum with an integer for inequality
<	**(1) Signature**: *[const]* bool **<** (const EdgeMode other) **Description**: Returns true if the first enum is less (in the enum symbol order) than the second **(2) Signature**: *[const]* bool **<** (int other) **Description**: Returns true if the enum is less (in the enum symbol order) than the integer value
==	**(1) Signature**: *[const]* bool **==** (const EdgeMode other) **Description**: Compares two enums **(2) Signature**: *[const]* bool **==** (int other) **Description**: Compares an enum with an integer value
All	**Signature**: *[static,const]* EdgeMode **All** **Description**: Selects all edges **Python specific notes:** The object exposes a readable attribute 'All'. This is the getter.
Concave	**Signature**: *[static,const]* EdgeMode **Concave** **Description**: Selects only concave edges **Python specific notes:** The object exposes a readable attribute 'Concave'. This is the getter.
Convex	**Signature**: *[static,const]* EdgeMode **Convex** **Description**: Selects only convex edges **Python specific notes:** The object exposes a readable attribute 'Convex'. This is the getter.
NotConcave	**Signature**: *[static,const]* EdgeMode **NotConcave** **Description**: Selects only edges which are not concave **Python specific notes:** The object exposes a readable attribute 'NotConcave'. This is the getter.
NotConvex	**Signature**: *[static,const]* EdgeMode **NotConvex** **Description**: Selects only edges which are not convex **Python specific notes:** The object exposes a readable attribute 'NotConvex'. This is the getter.
NotStep	**Signature**: *[static,const]* EdgeMode **NotStep** **Description**: Selects only edges which are not steps **Python specific notes:** The object exposes a readable attribute 'NotStep'. This is the getter.
NotStepIn	**Signature**: *[static,const]* EdgeMode **NotStepIn** **Description**: Selects only edges which are not steps leading inside

Python specific notes:
The object exposes a readable attribute 'NotStepIn'. This is the getter.

NotStepOut

Signature: *[static,const]* EdgeMode **NotStepOut**

Description: Selects only edges which are not steps leading outside

Python specific notes:
The object exposes a readable attribute 'NotStepOut'. This is the getter.

Step

Signature: *[static,const]* EdgeMode **Step**

Description: Selects only step edges leading inside or outside

Python specific notes:
The object exposes a readable attribute 'Step'. This is the getter.

StepIn

Signature: *[static,const]* EdgeMode **StepIn**

Description: Selects only step edges leading inside

Python specific notes:
The object exposes a readable attribute 'StepIn'. This is the getter.

StepOut

Signature: *[static,const]* EdgeMode **StepOut**

Description: Selects only step edges leading outside

Python specific notes:
The object exposes a readable attribute 'StepOut'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const EdgeMode other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new EdgeMode ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

hash

Signature: *[const]* int **hash**

Description: Gets the hash value from the enum

Python specific notes:

This method is also available as 'hash(object)'.

inspect

Signature: *[const]* string **inspect**

Description: Converts an enum to a visual string

Python specific notes:
This method is also available as 'repr(object)'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

(1) Signature: *[static]* new EdgeMode ptr **new** (int i)

Description: Creates an enum from an integer value

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new EdgeMode ptr **new** (string s)

Description: Creates an enum from a string value

Python specific notes:
This method is the default initializer of the object.

to_i

Signature: *[const]* int **to_i**

Description: Gets the integer value from the enum

Python specific notes:
This method is also available as 'int(object)'.

to_s

Signature: *[const]* string **to_s**

Description: Gets the symbolic string from an enum

Python specific notes:
This method is also available as 'str(object)'.

4.92. API reference - Class ZeroDistanceMode

Notation used in Ruby API documentation

Module: db

Description: This class represents the zero_distance_mode type for \Region#width and related checks.

This mode determines how edges with zero distance are treated in the DRC checks. Formally these edges do neither represent a space other other relation as they do not face each other. There are three modes available to treat this boundary case: Ignore such edges (NeverIncludeZeroDistance) or only include them if they share at least one common point (IncludeZeroDistanceWhenTouching). The latter mode allows activating checks for the 'kissing corner' case and is the default mode in most checks. This enum has been introduced in version 0.28.16.

Public constructors

new ZeroDistanceMode ptr	**new**	(int i)	Creates an enum from an integer value
new ZeroDistanceMode ptr	**new**	(string s)	Creates an enum from a string value

Public methods

[const]	bool	**!=**	(const ZeroDistanceMode other)	Compares two enums for inequality
[const]	bool	**!=**	(int other)	Compares an enum with an integer for inequality
[const]	bool	**<**	(const ZeroDistanceMode other)	Returns true if the first enum is less (in the enum symbol order) than the second
[const]	bool	**<**	(int other)	Returns true if the enum is less (in the enum symbol order) than the integer value
[const]	bool	**==**	(const ZeroDistanceMode other)	Compares two enums
[const]	bool	**==**	(int other)	Compares an enum with an integer value
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.

	void	**assign**	(const ZeroDistanceMode other)	Assigns another object to self
[const]	new ZeroDistanceMode ptr	**dup**		Creates a copy of self
[const]	int	**hash**		Gets the hash value from the enum
[const]	string	**inspect**		Converts an enum to a visual string
[const]	int	**to_i**		Gets the integer value from the enum
[const]	string	**to_s**		Gets the symbolic string from an enum

Public static methods and constants

[static,const]	ZeroDistanceMode	**IncludeZeroDistanceWhenC**	Specifies that check functions should include edges when they are collinear and touch
[static,const]	ZeroDistanceMode	**IncludeZeroDistanceWhenOverlapping**	Specifies that check functions should include edges when they overlap
[static,const]	ZeroDistanceMode	**IncludeZeroDistanceWhenT**	Specifies that check functions should include edges when they touch
[static,const]	ZeroDistanceMode	**NeverIncludeZeroDistance**	Specifies that check functions should never include edges with zero distance.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

!=	**(1) Signature**: *[const]* bool **!=** (const ZeroDistanceMode other) **Description**: Compares two enums for inequality **(2) Signature**: *[const]* bool **!=** (int other) **Description**: Compares an enum with an integer for inequality
<	**(1) Signature**: *[const]* bool **<** (const ZeroDistanceMode other)

Description: Returns true if the first enum is less (in the enum symbol order) than the second

(2) Signature: *[const]* bool **<** (int other)

Description: Returns true if the enum is less (in the enum symbol order) than the integer value

==

(1) Signature: *[const]* bool **==** (const ZeroDistanceMode other)

Description: Compares two enums

(2) Signature: *[const]* bool **==** (int other)

Description: Compares an enum with an integer value

IncludeZeroDistanceWhenCollinearAndTouching

Signature: *[static,const]* ZeroDistanceMode **IncludeZeroDistanceWhenCollinearAndTouching**

Description: Specifies that check functions should include edges when they are collinear and touch

With this specification, the check functions will also check edges if they share at least one common point and are collinear. This is the mode that includes checking the 'kissing corner' cases when the kissing edges are collinear. This mode was default up to version 0.28.

Python specific notes:
The object exposes a readable attribute 'IncludeZeroDistanceWhenCollinearAndTouching'. This is the getter.

IncludeZeroDistanceWhenO

Signature: *[static,const]* ZeroDistanceMode **IncludeZeroDistanceWhenOverlapping**

Description: Specifies that check functions should include edges when they overlap

With this specification, the check functions will also check edges which are collinear and share more than a single point. This is the mode that excludes the 'kissing corner' cases.

Python specific notes:
The object exposes a readable attribute 'IncludeZeroDistanceWhenOverlapping'. This is the getter.

IncludeZeroDistanceWhenTouching

Signature: *[static,const]* ZeroDistanceMode **IncludeZeroDistanceWhenTouching**

Description: Specifies that check functions should include edges when they touch

With this specification, the check functions will also check edges if they share at least one common point. This is the mode that includes checking the 'kissing corner' cases. This mode is default for version 0.28.16 and later.

Python specific notes:
The object exposes a readable attribute 'IncludeZeroDistanceWhenTouching'. This is the getter.

NeverIncludeZeroDistance

Signature: *[static,const]* ZeroDistanceMode **NeverIncludeZeroDistance**

Description: Specifies that check functions should never include edges with zero distance.

With this specification, the check functions will ignore edges which are collinear or touch.

Python specific notes:
The object exposes a readable attribute 'NeverIncludeZeroDistance'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const ZeroDistanceMode other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new ZeroDistanceMode ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

hash

Signature: *[const]* int **hash**

Description: Gets the hash value from the enum

Python specific notes:
This method is also available as 'hash(object)'.

inspect

Signature: *[const]* string **inspect**

Description: Converts an enum to a visual string

Python specific notes:
This method is also available as 'repr(object)'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

(1) Signature: *[static]* new ZeroDistanceMode ptr **new** (int i)

Description: Creates an enum from an integer value

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new ZeroDistanceMode ptr **new** (string s)

Description: Creates an enum from a string value

Python specific notes:
This method is the default initializer of the object.

to_i

Signature: *[const]* int **to_i**

Description: Gets the integer value from the enum

Python specific notes:
This method is also available as 'int(object)'.

to_s

Signature: *[const]* string **to_s**

Description: Gets the symbolic string from an enum

Python specific notes:
This method is also available as 'str(object)'.

4.93. API reference - Class PropertyConstraint

Notation used in Ruby API documentation

Module: db

Description: This class represents the property constraint for boolean and check functions.

This enum has been introduced in version 0.28.4.

Public constructors

new PropertyConstraint ptr	**new**	(int i)	Creates an enum from an integer value
new PropertyConstraint ptr	**new**	(string s)	Creates an enum from a string value

Public methods

[const]	bool	**!=**	(const PropertyConstrain other)	Compares two enums for inequality
[const]	bool	**!=**	(int other)	Compares an enum with an integer for inequality
[const]	bool	**<**	(const PropertyConstrain other)	Returns true if the first enum is less (in the enum symbol order) than the second
[const]	bool	**<**	(int other)	Returns true if the enum is less (in the enum symbol order) than the integer value
[const]	bool	**==**	(const PropertyConstrain other)	Compares two enums
[const]	bool	**==**	(int other)	Compares an enum with an integer value
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const PropertyConstrain other)	Assigns another object to self

[const]	new PropertyConstraint ptr	**dup**	Creates a copy of self
[const]	int	**hash**	Gets the hash value from the enum
[const]	string	**inspect**	Converts an enum to a visual string
[const]	int	**to_i**	Gets the integer value from the enum
[const]	string	**to_s**	Gets the symbolic string from an enum

Public static methods and constants

[static,const]	PropertyConstraint	**DifferentPropertiesConstrai**	Specifies to consider shapes only if their user properties are different
[static,const]	PropertyConstraint	**DifferentPropertiesConstraintDrop**	Specifies to consider shapes only if their user properties are different
[static,const]	PropertyConstraint	**IgnoreProperties**	Specifies to ignore properties
[static,const]	PropertyConstraint	**NoPropertyConstraint**	Specifies not to apply any property constraint
[static,const]	PropertyConstraint	**SamePropertiesConstraint**	Specifies to consider shapes only if their user properties are the same
[static,const]	PropertyConstraint	**SamePropertiesConstraintDrop**	Specifies to consider shapes only if their user properties are the same

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

!=	**(1) Signature**: *[const]* bool **!=** (const PropertyConstraint other) **Description**: Compares two enums for inequality **(2) Signature**: *[const]* bool **!=** (int other) **Description**: Compares an enum with an integer for inequality
<	**(1) Signature**: *[const]* bool **<** (const PropertyConstraint other)

Description: Returns true if the first enum is less (in the enum symbol order) than the second

(2) Signature: *[const]* bool **<** (int other)

Description: Returns true if the enum is less (in the enum symbol order) than the integer value

==

(1) Signature: *[const]* bool **==** (const PropertyConstraint other)

Description: Compares two enums

(2) Signature: *[const]* bool **==** (int other)

Description: Compares an enum with an integer value

DifferentPropertiesConstraint

Signature: *[static,const]* PropertyConstraint **DifferentPropertiesConstraint**

Description: Specifies to consider shapes only if their user properties are different

When using this constraint - for example on a boolean operation - shapes are considered only if their user properties are different. Properties are generated on the output shapes where applicable.

Python specific notes:
The object exposes a readable attribute 'DifferentPropertiesConstraint'. This is the getter.

DifferentPropertiesConstrai

Signature: *[static,const]* PropertyConstraint **DifferentPropertiesConstraintDrop**

Description: Specifies to consider shapes only if their user properties are different

When using this constraint - for example on a boolean operation - shapes are considered only if their user properties are the same. No properties are generated on the output shapes.

Python specific notes:
The object exposes a readable attribute 'DifferentPropertiesConstraintDrop'. This is the getter.

IgnoreProperties

Signature: *[static,const]* PropertyConstraint **IgnoreProperties**

Description: Specifies to ignore properties

When using this constraint - for example on a boolean operation - properties are ignored and are not generated in the output.

Python specific notes:
The object exposes a readable attribute 'IgnoreProperties'. This is the getter.

NoPropertyConstraint

Signature: *[static,const]* PropertyConstraint **NoPropertyConstraint**

Description: Specifies not to apply any property constraint

When using this constraint - for example on a boolean operation - shapes are considered regardless of their user properties. Properties are generated on the output shapes where applicable.

Python specific notes:
The object exposes a readable attribute 'NoPropertyConstraint'. This is the getter.

SamePropertiesConstraint

Signature: *[static,const]* PropertyConstraint **SamePropertiesConstraint**

Description: Specifies to consider shapes only if their user properties are the same

When using this constraint - for example on a boolean operation - shapes are considered only if their user properties are the same. Properties are generated on the output shapes where applicable.

Python specific notes:
The object exposes a readable attribute 'SamePropertiesConstraint'. This is the getter.

SamePropertiesConstraintD

Signature: *[static,const]* PropertyConstraint **SamePropertiesConstraintDrop**

Description: Specifies to consider shapes only if their user properties are the same

When using this constraint - for example on a boolean operation - shapes are considered only if their user properties are the same. No properties are generated on the output shapes.

Python specific notes:
The object exposes a readable attribute 'SamePropertiesConstraintDrop'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const PropertyConstraint other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new PropertyConstraint ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

hash

Signature: *[const]* int **hash**

Description: Gets the hash value from the enum

Python specific notes:
This method is also available as 'hash(object)'.

inspect

Signature: *[const]* string **inspect**

Description: Converts an enum to a visual string

Python specific notes:
This method is also available as 'repr(object)'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

(1) Signature: *[static]* new PropertyConstraint ptr **new** (int i)

Description: Creates an enum from an integer value

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new PropertyConstraint ptr **new** (string s)

Description: Creates an enum from a string value

Python specific notes:
This method is the default initializer of the object.

to_i

Signature: *[const]* int **to_i**

Description: Gets the integer value from the enum

Python specific notes:
This method is also available as 'int(object)'.

to_s

Signature: *[const]* string **to_s**

Description: Gets the symbolic string from an enum

Python specific notes:
This method is also available as 'str(object)'.

4.94. API reference - Class Shape

Notation used in Ruby API documentation

Module: db

Description: An object representing a shape in the layout database

The shape proxy is basically a pointer to a shape of different kinds. No copy of the shape is created: if the shape proxy is copied the copy still points to the original shape. If the original shape is modified or deleted, the shape proxy will also point to a modified or invalid shape. The proxy can be "null" which indicates an invalid reference.

Shape objects are used together with the Shapes container object which stores the actual shape objects and uses Shape references as pointers inside the actual data storage. Shape references are used in various places, i.e. when removing or transforming objects inside a Shapes container.

Public constructors

new Shape ptr	**new**		Creates a new object of this class

Public methods

[const]	bool	**!=**	(const Shape other)	Inequality operator
[const]	bool	**==**	(const Shape other)	Equality operator
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	long	**area**		Returns the area of the shape
[const]	DTrans	**array_dtrans**		Gets the array instance member transformation in micrometer units
[const]	Trans	**array_trans**		Gets the array instance member transformation
	void	**assign**	(const Shape other)	Assigns another object to self
[const]	Box	**bbox**		Returns the bounding box of the shape
[const]	variant	**box**		Gets the box object

	void	**box=**	(const Box box)	Replaces the shape by the given box
	void	**box=**	(const DBox box)	Replaces the shape by the given box (in micrometer units)
[const]	Point	**box_center**		Returns the center of the box
	void	**box_center=**	(const Point c)	Sets the center of the box
	void	**box_center=**	(const DPoint c)	Sets the center of the box with the point being given in micrometer units
[const]	DPoint	**box_dcenter**		Returns the center of the box as a DPoint object in micrometer units
	void	**box_dcenter=**	(const DPoint c)	Sets the center of the box with the point being given in micrometer units
[const]	double	**box_dheight**		Returns the height of the box in micrometer units
	void	**box_dheight=**	(double h)	Sets the height of the box
[const]	DPoint	**box_dp1**		Returns the lower left point of the box as a DPoint object in micrometer units
	void	**box_dp1=**	(const DPoint p)	Sets the lower left corner of the box with the point being given in micrometer units
[const]	DPoint	**box_dp2**		Returns the upper right point of the box as a DPoint object in micrometer units
	void	**box_dp2=**	(const DPoint p)	Sets the upper right corner of the box with the point being given in micrometer units
[const]	double	**box_dwidth**		Returns the width of the box in micrometer units
	void	**box_dwidth=**	(double w)	Sets the width of the box in micrometer units
[const]	int	**box_height**		Returns the height of the box
	void	**box_height=**	(int h)	Sets the height of the box
[const]	Point	**box_p1**		Returns the lower left point of the box
	void	**box_p1=**	(const Point p)	Sets the lower left point of the box
	void	**box_p1=**	(const DPoint p)	Sets the lower left corner of the box with the point being given in micrometer units
[const]	Point	**box_p2**		Returns the upper right point of the box
	void	**box_p2=**	(const Point p)	Sets the upper right point of the box
	void	**box_p2=**	(const DPoint p)	Sets the upper right corner of the box with the point being given in micrometer units

[const]	int	**box_width**		Returns the width of the box
	void	**box_width=**	(int w)	Sets the width of the box
	Cell ptr	**cell**		Gets a reference to the cell the shape belongs to
	void	**cell=**	(Cell ptr cell)	Moves the shape to a different cell
[const]	double	**darea**		Returns the area of the shape in square micrometer units
[const]	DBox	**dbbox**		Returns the bounding box of the shape in micrometer units
[const]	variant	**dbox**		Gets the box object in micrometer units
	void	**dbox=**	(const DBox box)	Replaces the shape by the given box (in micrometer units)
[const]	variant	**dedge**		Returns the edge object as a DEdge object in micrometer units
	void	**dedge=**	(const DEdge edge)	Replaces the shape by the given edge (in micrometer units)
[const]	variant	**dedge_pair**		Returns the edge pair object as a DEdgePair object in micrometer units
	void	**dedge_pair=**	(const DEdgePair edge_pair)	Replaces the shape by the given edge pair (in micrometer units)
	void	**delete**		Deletes the shape
	void	**delete_property**	(variant key)	Deletes the user property with the given key
[const]	variant	**dpath**		Returns the path object as a DPath object in micrometer units
	void	**dpath=**	(const DPath path)	Replaces the shape by the given path (in micrometer units)
[const]	double	**dperimeter**		Returns the perimeter of the shape in micrometer units
[const]	variant	**dpoint**		Returns the point object as a DPoint object in micrometer units
	void	**dpoint=**	(const DPoint point)	Replaces the shape by the given point (in micrometer units)
[const]	variant	**dpolygon**		Returns the polygon object in micrometer units
	void	**dpolygon=**	(const DPolygon polygon)	Replaces the shape by the given polygon (in micrometer units)

[const]	variant	**drectangle**		Gets the rectangle in micron units if the object represents one or nil if not
[const]	variant	**dsimple_polygon**		Returns the simple polygon object in micrometer units
	void	**dsimple_polygon=**	(const DSimplePolygon polygon)	Replaces the shape by the given simple polygon (in micrometer units)
[const]	variant	**dtext**		Returns the path object as a DText object in micrometer units
	void	**dtext=**	(const DText text)	Replaces the shape by the given text (in micrometer units)
[const]	new Shape ptr	**dup**		Creates a copy of self
[const,iter]	DEdge	**each_dedge**		Iterates over the edges of the object and returns edges in micrometer units
[const,iter]	DEdge	**each_dedge**	(unsigned int contour)	Iterates over the edges of a single contour of the object and returns edges in micrometer units
[const,iter]	DPoint	**each_dpoint**		Iterates over all points of the object and returns points in micrometer units
[const,iter]	DPoint	**each_dpoint_hole**	(unsigned int hole_index)	Iterates over a hole contour of the object and returns points in micrometer units
[const,iter]	DPoint	**each_dpoint_hull**		Iterates over the hull contour of the object and returns points in micrometer units
[const,iter]	Edge	**each_edge**		Iterates over the edges of the object
[const,iter]	Edge	**each_edge**	(unsigned int contour)	Iterates over the edges of a single contour of the object
[const,iter]	Point	**each_point**		Iterates over all points of the object
[const,iter]	Point	**each_point_hole**	(unsigned int hole_index)	Iterates over the points of a hole contour
[const,iter]	Point	**each_point_hull**		Iterates over the hull contour of the object
[const]	variant	**edge**		Returns the edge object
	void	**edge=**	(const Edge edge)	Replaces the shape by the given edge
	void	**edge=**	(const DEdge edge)	Replaces the shape by the given edge (in micrometer units)
[const]	variant	**edge_pair**		Returns the edge pair object
	void	**edge_pair=**	(const EdgePair edge_pair)	Replaces the shape by the given edge pair

	void	**edge_pair=**	(const DEdgePair edge_pair)	Replaces the shape by the given edge pair (in micrometer units)
[const]	bool	**has_prop_id?**		Returns true, if the shape has properties, i.e. has a properties ID
[const]	unsigned int	**holes**		Returns the number of holes
[const]	bool	**is_array_member?**		Returns true, if the shape is a member of a shape array
[const]	bool	**is_box?**		Returns true if the shape is a box
[const]	bool	**is_edge?**		Returns true, if the object is an edge
[const]	bool	**is_edge_pair?**		Returns true, if the object is an edge pair
[const]	bool	**is_null?**		Returns true, if the shape reference is a null reference (not referring to a shape)
[const]	bool	**is_path?**		Returns true, if the shape is a path
[const]	bool	**is_point?**		Returns true, if the object is an point
[const]	bool	**is_polygon?**		Returns true, if the shape is a polygon
[const]	bool	**is_simple_polygon?**		Returns true, if the shape is a simple polygon
[const]	bool	**is_text?**		Returns true, if the object is a text
[const]	bool	**is_user_object?**		Returns true if the shape is a user defined object
[const]	bool	**is_valid?**		Returns true, if the shape is valid
[const]	unsigned int	**layer**		Returns the layer index of the layer the shape is on
	void	**layer=**	(unsigned int layer_index)	Moves the shape to a layer given by the layer index object
[const]	LayerInfo	**layer_info**		Returns the LayerInfo object of the layer the shape is on
	void	**layer_info=**	(const LayerInfo layer_info)	Moves the shape to a layer given by a LayerInfo object
	Layout ptr	**layout**		Gets a reference to the Layout the shape belongs to
[const]	variant	**path**		Returns the path object
	void	**path=**	(const Path box)	Replaces the shape by the given path object

	void	**path=**	(const DPath path)	Replaces the shape by the given path (in micrometer units)
[const]	int	**path_bgnext**		Gets the path's starting vertex extension
	void	**path_bgnext=**	(int e)	Sets the path's starting vertex extension
[const]	double	**path_dbgnext**		Gets the path's starting vertex extension in micrometer units
	void	**path_dbgnext=**	(double e)	Sets the path's starting vertex extension in micrometer units
[const]	double	**path_dendext**		Gets the path's end vertex extension in micrometer units
	void	**path_dendext=**	(double e)	Sets the path's end vertex extension in micrometer units
[const]	double	**path_dlength**		Returns the length of the path in micrometer units
[const]	double	**path_dwidth**		Gets the path width in micrometer units
	void	**path_dwidth=**	(double w)	Sets the path width in micrometer units
[const]	int	**path_endext**		Obtain the path's end vertex extension
	void	**path_endext=**	(int e)	Sets the path's end vertex extension
[const]	int	**path_length**		Returns the length of the path
[const]	int	**path_width**		Gets the path width
	void	**path_width=**	(int w)	Sets the path width
[const]	unsigned long	**perimeter**		Returns the perimeter of the shape
[const]	variant	**point**		Returns the point object
	void	**point=**	(const Point point)	Replaces the shape by the given point
	void	**point=**	(const DPoint point)	Replaces the shape by the given point (in micrometer units)
[const]	variant	**polygon**		Returns the polygon object
	void	**polygon=**	(const Polygon box)	Replaces the shape by the given polygon object
	void	**polygon=**	(const DPolygon polygon)	Replaces the shape by the given polygon (in micrometer units)
[const]	unsigned long	**prop_id**		Gets the properties ID associated with the shape

	void	**prop_id=**	(unsigned long id)	Sets the properties ID of this shape
[const]	variant	**property**	(variant key)	Gets the user property with the given key
[const]	variant	**rectangle**		Gets the rectangle if the object represents one or nil if not
	void	**round_path=**	(bool r)	The path will be a round-ended path if this property is set to true
[const]	bool	**round_path?**		Returns true, if the path has round ends
	void	**set_property**	(variant key, variant value)	Sets the user property with the given key to the given value
	Shapes ptr	**shapes**		Gets a reference to the Shapes container the shape lives in
[const]	variant	**simple_polygon**		Returns the simple polygon object
	void	**simple_polygon=**	(const SimplePolygon polygon)	Replaces the shape by the given simple polygon object
	void	**simple_polygon=**	(const DSimplePolygon polygon)	Replaces the shape by the given simple polygon (in micrometer units)
[const]	variant	**text**		Returns the text object
	void	**text=**	(const Text box)	Replaces the shape by the given text object
	void	**text=**	(const DText text)	Replaces the shape by the given text (in micrometer units)
[const]	DVector	**text_dpos**		Gets the text's position in micrometer units
	void	**text_dpos=**	(const DVector p)	Sets the text's position in micrometer units
[const]	double	**text_dsize**		Gets the text size in micrometer units
	void	**text_dsize=**	(double size)	Sets the text size in micrometer units
[const]	DTrans	**text_dtrans**		Gets the text transformation in micrometer units
	void	**text_dtrans=**	(const DTrans trans)	Sets the text transformation in micrometer units
[const]	int	**text_font**		Gets the text's font
	void	**text_font=**	(int font)	Sets the text's font
[const]	int	**text_halign**		Gets the text's horizontal alignment
	void	**text_halign=**	(int a)	Sets the text's horizontal alignment

[const]	Vector	**text_pos**		Gets the text's position
	void	**text_pos=**	(const Vector p)	Sets the text's position
	void	**text_pos=**	(const DVector p)	Sets the text's position in micrometer units
[const]	int	**text_rot**		Gets the text's orientation code (see Trans)
	void	**text_rot=**	(int o)	Sets the text's orientation code (see Trans)
[const]	int	**text_size**		Gets the text size
	void	**text_size=**	(int size)	Sets the text size
[const]	string	**text_string**		Obtain the text string
	void	**text_string=**	(string string)	Sets the text string
[const]	Trans	**text_trans**		Gets the text transformation
	void	**text_trans=**	(const Trans trans)	Sets the text transformation
	void	**text_trans=**	(const DTrans trans)	Sets the text transformation in micrometer units
[const]	int	**text_valign**		Gets the text's vertical alignment
	void	**text_valign=**	(int a)	Sets the text's vertical alignment
[const]	string	**to_s**		Create a string showing the contents of the reference
	void	**transform**	(const Trans trans)	Transforms the shape with the given transformation
	void	**transform**	(const DTrans trans)	Transforms the shape with the given transformation, given in micrometer units
	void	**transform**	(const ICplxTrans trans)	Transforms the shape with the given complex transformation
	void	**transform**	(const DCplxTrans trans)	Transforms the shape with the given complex transformation, given in micrometer units
[const]	int	**type**		Return the type of the shape

Detailed description

!=

Signature: *[const]* bool **!=** (const Shape other)

Description: Inequality operator

==

Signature: *[const]* bool **==** (const Shape other)

Description: Equality operator

Equality of shapes is not specified by the identity of the objects but by the identity of the pointers - both shapes must refer to the same object.

TBox

Signature: *[static]* int **TBox**

Description:

Python specific notes:
The object exposes a readable attribute 'TBox'. This is the getter.

TBoxArray

Signature: *[static]* int **TBoxArray**

Description:

Python specific notes:
The object exposes a readable attribute 'TBoxArray'. This is the getter.

TBoxArrayMember

Signature: *[static]* int **TBoxArrayMember**

Description:

Python specific notes:
The object exposes a readable attribute 'TBoxArrayMember'. This is the getter.

TEdge

Signature: *[static]* int **TEdge**

Description:

Python specific notes:
The object exposes a readable attribute 'TEdge'. This is the getter.

TEdgePair

Signature: *[static]* int **TEdgePair**

Description:

Python specific notes:
The object exposes a readable attribute 'TEdgePair'. This is the getter.

TNull

Signature: *[static]* int **TNull**

Description:

Python specific notes:
The object exposes a readable attribute 'TNull'. This is the getter.

TPath

Signature: *[static]* int **TPath**

Description:

Python specific notes:
The object exposes a readable attribute 'TPath'. This is the getter.

TPathPtrArray

Signature: *[static]* int **TPathPtrArray**

Description:

Python specific notes:
The object exposes a readable attribute 'TPathPtrArray'. This is the getter.

TPathPtrArrayMember

Signature: *[static]* int **TPathPtrArrayMember**

Description:

Python specific notes:
The object exposes a readable attribute 'TPathPtrArrayMember'. This is the getter.

TPathRef

Signature: *[static]* int **TPathRef**

Description:

Python specific notes:
The object exposes a readable attribute 'TPathRef'. This is the getter.

TPoint

Signature: *[static]* int **TPoint**

Description:

Python specific notes:
The object exposes a readable attribute 'TPoint'. This is the getter.

TPolygon

Signature: *[static]* int **TPolygon**

Description:

Python specific notes:
The object exposes a readable attribute 'TPolygon'. This is the getter.

TPolygonPtrArray

Signature: *[static]* int **TPolygonPtrArray**

Description:

Python specific notes:

	The object exposes a readable attribute 'TPolygonPtrArray'. This is the getter.
TPolygonPtrArrayMember	**Signature**: *[static]* int **TPolygonPtrArrayMember** **Description**: **Python specific notes:** The object exposes a readable attribute 'TPolygonPtrArrayMember'. This is the getter.
TPolygonRef	**Signature**: *[static]* int **TPolygonRef** **Description**: **Python specific notes:** The object exposes a readable attribute 'TPolygonRef'. This is the getter.
TShortBox	**Signature**: *[static]* int **TShortBox** **Description**: **Python specific notes:** The object exposes a readable attribute 'TShortBox'. This is the getter.
TShortBoxArray	**Signature**: *[static]* int **TShortBoxArray** **Description**: **Python specific notes:** The object exposes a readable attribute 'TShortBoxArray'. This is the getter.
TShortBoxArrayMember	**Signature**: *[static]* int **TShortBoxArrayMember** **Description**: **Python specific notes:** The object exposes a readable attribute 'TShortBoxArrayMember'. This is the getter.
TSimplePolygon	**Signature**: *[static]* int **TSimplePolygon** **Description**: **Python specific notes:** The object exposes a readable attribute 'TSimplePolygon'. This is the getter.
TSimplePolygonPtrArray	**Signature**: *[static]* int **TSimplePolygonPtrArray** **Description**: **Python specific notes:** The object exposes a readable attribute 'TSimplePolygonPtrArray'. This is the getter.
TSimplePolygonPtrArrayM	**Signature**: *[static]* int **TSimplePolygonPtrArrayMember** **Description**: **Python specific notes:** The object exposes a readable attribute 'TSimplePolygonPtrArrayMember'. This is the getter.
TSimplePolygonRef	**Signature**: *[static]* int **TSimplePolygonRef** **Description**: **Python specific notes:** The object exposes a readable attribute 'TSimplePolygonRef'. This is the getter.

TText

Signature: *[static]* int **TText**

Description:

Python specific notes:
The object exposes a readable attribute 'TText'. This is the getter.

TTextPtrArray

Signature: *[static]* int **TTextPtrArray**

Description:

Python specific notes:
The object exposes a readable attribute 'TTextPtrArray'. This is the getter.

TTextPtrArrayMember

Signature: *[static]* int **TTextPtrArrayMember**

Description:

Python specific notes:
The object exposes a readable attribute 'TTextPtrArrayMember'. This is the getter.

TTextRef

Signature: *[static]* int **TTextRef**

Description:

Python specific notes:
The object exposes a readable attribute 'TTextRef'. This is the getter.

TUserObject

Signature: *[static]* int **TUserObject**

Description:

Python specific notes:
The object exposes a readable attribute 'TUserObject'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

area

Signature: *[const]* long **area**

Description: Returns the area of the shape

This method has been added in version 0.22.

array_dtrans

Signature: *[const]* DTrans **array_dtrans**

Description: Gets the array instance member transformation in micrometer units

This attribute is valid only if is_array_member? is true. The transformation returned describes the relative transformation of the array member addressed. The displacement is given in micrometer units.

This method has been added in version 0.25.

array_trans

Signature: *[const]* Trans **array_trans**

Description: Gets the array instance member transformation

This attribute is valid only if is_array_member? is true. The transformation returned describes the relative transformation of the array member addressed.

assign

Signature: void **assign** (const Shape other)

Description: Assigns another object to self

bbox

Signature: *[const]* Box **bbox**

Description: Returns the bounding box of the shape

box

Signature: *[const]* variant **box**

Description: Gets the box object

Starting with version 0.23, this method returns nil, if the shape does not represent a box.

Python specific notes:
The object exposes a readable attribute 'box'. This is the getter.

box=

(1) Signature: void **box=** (const Box box)

Description: Replaces the shape by the given box

This method replaces the shape by the given box. This method can only be called for editable layouts. It does not change the user properties of the shape. Calling this method will invalidate any iterators. It should not be called inside a loop iterating over shapes.

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a writable attribute 'box'. This is the setter.

(2) Signature: void **box=** (const DBox box)

Description: Replaces the shape by the given box (in micrometer units)

This method replaces the shape by the given box, like box= with a Box argument does. This version translates the box from micrometer units to database units internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'box'. This is the setter.
The object exposes a writable attribute 'dbox'. This is the setter.

box_center

Signature: *[const]* Point **box_center**

Description: Returns the center of the box

Applies to boxes only. Returns the center of the box and throws an exception if the shape is not a box.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a readable attribute 'box_center'. This is the getter.

box_center=

(1) Signature: void **box_center=** (const Point c)

Description: Sets the center of the box

Applies to boxes only. Changes the center of the box and throws an exception if the shape is not a box.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'box_center'. This is the setter.

(2) Signature: void **box_center=** (const DPoint c)

Description: Sets the center of the box with the point being given in micrometer units

Applies to boxes only. Changes the center of the box and throws an exception if the shape is not a box. Translation from micrometer units to database units is done internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'box_center'. This is the setter.
The object exposes a writable attribute 'box_dcenter'. This is the setter.

box_dcenter

Signature: *[const]* DPoint **box_dcenter**

Description: Returns the center of the box as a DPoint object in micrometer units

Applies to boxes only. Returns the center of the box and throws an exception if the shape is not a box. Conversion from database units to micrometers is done internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'box_dcenter'. This is the getter.

box_dcenter=

Signature: void **box_dcenter=** (const DPoint c)

Description: Sets the center of the box with the point being given in micrometer units

Applies to boxes only. Changes the center of the box and throws an exception if the shape is not a box. Translation from micrometer units to database units is done internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'box_center'. This is the setter.
The object exposes a writable attribute 'box_dcenter'. This is the setter.

box_dheight

Signature: *[const]* double **box_dheight**

Description: Returns the height of the box in micrometer units

Applies to boxes only. Returns the height of the box in micrometers and throws an exception if the shape is not a box.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'box_dheight'. This is the getter.

box_dheight=

Signature: void **box_dheight=** (double h)

Description: Sets the height of the box

Applies to boxes only. Changes the height of the box to the value given in micrometer units and throws an exception if the shape is not a box. Translation to database units happens internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'box_dheight'. This is the setter.

box_dp1

Signature: *[const]* DPoint **box_dp1**

Description: Returns the lower left point of the box as a DPoint object in micrometer units

Applies to boxes only. Returns the lower left point of the box and throws an exception if the shape is not a box. Conversion from database units to micrometers is done internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'box_dp1'. This is the getter.

box_dp1=

Signature: void **box_dp1=** (const DPoint p)

Description: Sets the lower left corner of the box with the point being given in micrometer units

Applies to boxes only. Changes the lower left point of the box and throws an exception if the shape is not a box. Translation from micrometer units to database units is done internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'box_p1'. This is the setter.

The object exposes a writable attribute 'box_dp1'. This is the setter.

box_dp2

Signature: *[const]* DPoint **box_dp2**

Description: Returns the upper right point of the box as a DPoint object in micrometer units

Applies to boxes only. Returns the upper right point of the box and throws an exception if the shape is not a box. Conversion from database units to micrometers is done internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'box_dp2'. This is the getter.

box_dp2=

Signature: void **box_dp2=** (const DPoint p)

Description: Sets the upper right corner of the box with the point being given in micrometer units

Applies to boxes only. Changes the upper right point of the box and throws an exception if the shape is not a box. Translation from micrometer units to database units is done internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'box_p2'. This is the setter.
The object exposes a writable attribute 'box_dp2'. This is the setter.

box_dwidth

Signature: *[const]* double **box_dwidth**

Description: Returns the width of the box in micrometer units

Applies to boxes only. Returns the width of the box in micrometers and throws an exception if the shape is not a box.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'box_dwidth'. This is the getter.

box_dwidth=

Signature: void **box_dwidth=** (double w)

Description: Sets the width of the box in micrometer units

Applies to boxes only. Changes the width of the box to the value given in micrometer units and throws an exception if the shape is not a box. Translation to database units happens internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'box_dwidth'. This is the setter.

box_height

Signature: *[const]* int **box_height**

Description: Returns the height of the box

Applies to boxes only. Returns the height of the box and throws an exception if the shape is not a box.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a readable attribute 'box_height'. This is the getter.

box_height=

Signature: void **box_height=** (int h)

Description: Sets the height of the box

Applies to boxes only. Changes the height of the box and throws an exception if the shape is not a box.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'box_height'. This is the setter.

box_p1

Signature: *[const]* Point **box_p1**

Description: Returns the lower left point of the box

Applies to boxes only. Returns the lower left point of the box and throws an exception if the shape is not a box.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a readable attribute 'box_p1'. This is the getter.

box_p1=

(1) Signature: void **box_p1=** (const Point p)

Description: Sets the lower left point of the box

Applies to boxes only. Changes the lower left point of the box and throws an exception if the shape is not a box.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'box_p1'. This is the setter.

(2) Signature: void **box_p1=** (const DPoint p)

Description: Sets the lower left corner of the box with the point being given in micrometer units

Applies to boxes only. Changes the lower left point of the box and throws an exception if the shape is not a box. Translation from micrometer units to database units is done internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'box_p1'. This is the setter.
The object exposes a writable attribute 'box_dp1'. This is the setter.

box_p2

Signature: *[const]* Point **box_p2**

Description: Returns the upper right point of the box

Applies to boxes only. Returns the upper right point of the box and throws an exception if the shape is not a box.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a readable attribute 'box_p2'. This is the getter.

box_p2=

(1) Signature: void **box_p2=** (const Point p)

Description: Sets the upper right point of the box

Applies to boxes only. Changes the upper right point of the box and throws an exception if the shape is not a box.

This method has been introduced in version 0.23.

Python specific notes:

The object exposes a writable attribute 'box_p2'. This is the setter.

(2) Signature: void **box_p2=** (const DPoint p)

Description: Sets the upper right corner of the box with the point being given in micrometer units

Applies to boxes only. Changes the upper right point of the box and throws an exception if the shape is not a box. Translation from micrometer units to database units is done internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'box_p2'. This is the setter.
The object exposes a writable attribute 'box_dp2'. This is the setter.

box_width

Signature: *[const]* int **box_width**

Description: Returns the width of the box

Applies to boxes only. Returns the width of the box and throws an exception if the shape is not a box.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a readable attribute 'box_width'. This is the getter.

box_width=

Signature: void **box_width=** (int w)

Description: Sets the width of the box

Applies to boxes only. Changes the width of the box and throws an exception if the shape is not a box.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'box_width'. This is the setter.

cell

Signature: Cell ptr **cell**

Description: Gets a reference to the cell the shape belongs to

This reference can be nil, if the Shape object is not living inside a cell

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'cell'. This is the getter.

cell=

Signature: void **cell=** (Cell ptr cell)

Description: Moves the shape to a different cell

Both the current and the target cell must reside in the same layout.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'cell'. This is the setter.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

darea

Signature: *[const]* double **darea**

Description: Returns the area of the shape in square micrometer units

This method has been added in version 0.25.

dbbox

Signature: *[const]* DBox **dbbox**

Description: Returns the bounding box of the shape in micrometer units

This method has been added in version 0.25.

dbox

Signature: *[const]* variant **dbox**

Description: Gets the box object in micrometer units

See box for a description of this method. This method returns the box after translation to micrometer units.

This method has been added in version 0.25.

Python specific notes:
The object exposes a readable attribute 'dbox'. This is the getter.

dbox=

Signature: void **dbox=** (const DBox box)

Description: Replaces the shape by the given box (in micrometer units)

This method replaces the shape by the given box, like box= with a Box argument does. This version translates the box from micrometer units to database units internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'box'. This is the setter.
The object exposes a writable attribute 'dbox'. This is the setter.

dedge

Signature: *[const]* variant **dedge**

Description: Returns the edge object as a DEdge object in micrometer units

See edge for a description of this method. This method returns the edge after translation to micrometer units.

This method has been added in version 0.25.

Python specific notes:
The object exposes a readable attribute 'dedge'. This is the getter.

dedge=

Signature: void **dedge=** (const DEdge edge)

Description: Replaces the shape by the given edge (in micrometer units)

This method replaces the shape by the given edge, like edge= with a Edge argument does. This version translates the edge from micrometer units to database units internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'edge'. This is the setter.
The object exposes a writable attribute 'dedge'. This is the setter.

dedge_pair

Signature: *[const]* variant **dedge_pair**

Description: Returns the edge pair object as a DEdgePair object in micrometer units

See edge_pair for a description of this method. This method returns the edge pair after translation to micrometer units.

This method has been added in version 0.26.

Python specific notes:
The object exposes a readable attribute 'dedge_pair'. This is the getter.

dedge_pair=

Signature: void **dedge_pair=** (const DEdgePair edge_pair)

Description: Replaces the shape by the given edge pair (in micrometer units)

This method replaces the shape by the given edge pair, like edge_pair= with a EdgePair argument does. This version translates the edge pair from micrometer units to database units internally.

This method has been introduced in version 0.26.

Python specific notes:
The object exposes a writable attribute 'edge_pair'. This is the setter.
The object exposes a writable attribute 'dedge_pair'. This is the setter.

delete

Signature: void **delete**

Description: Deletes the shape

After the shape is deleted, the shape object is emptied and points to nothing.

This method has been introduced in version 0.23.

delete_property

Signature: void **delete_property** (variant key)

Description: Deletes the user property with the given key

This method is a convenience method that deletes the property with the given key. It does nothing if no property with that key exists. Using that method is more convenient than creating a new property set with a new ID and assigning that properties ID. This method may change the properties ID. Calling this method will invalidate any iterators. It should not be called inside a loop iterating over shapes.

This method has been introduced in version 0.22.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dpath

Signature: *[const]* variant **dpath**

Description: Returns the path object as a DPath object in micrometer units

See path for a description of this method. This method returns the path after translation to micrometer units.

This method has been added in version 0.25.

Python specific notes:
The object exposes a readable attribute 'dpath'. This is the getter.

dpath=

Signature: void **dpath=** (const DPath path)

Description: Replaces the shape by the given path (in micrometer units)

This method replaces the shape by the given path, like path= with a Path argument does. This version translates the path from micrometer units to database units internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'path'. This is the setter.
The object exposes a writable attribute 'dpath'. This is the setter.

dperimeter

Signature: *[const]* double **dperimeter**

Description: Returns the perimeter of the shape in micrometer units

This method will return an approximation of the perimeter for paths.

This method has been added in version 0.25.

dpoint

Signature: *[const]* variant **dpoint**

Description: Returns the point object as a DPoint object in micrometer units

See point for a description of this method. This method returns the point after translation to micrometer units.

This method has been introduced in version 0.28.

Python specific notes:
The object exposes a readable attribute 'dpoint'. This is the getter.

dpoint=

Signature: void **dpoint=** (const DPoint point)

Description: Replaces the shape by the given point (in micrometer units)

This method replaces the shape by the given point, like point= with a Point argument does. This version translates the point from micrometer units to database units internally.

This method has been introduced in version 0.28.

Python specific notes:
The object exposes a writable attribute 'point'. This is the setter.
The object exposes a writable attribute 'dpoint'. This is the setter.

dpolygon

Signature: *[const]* variant **dpolygon**

Description: Returns the polygon object in micrometer units

Returns the polygon object that this shape refers to or converts the object to a polygon. The method returns the same object than polygon, but translates it to micrometer units internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'dpolygon'. This is the getter.

dpolygon=

Signature: void **dpolygon=** (const DPolygon polygon)

Description: Replaces the shape by the given polygon (in micrometer units)

This method replaces the shape by the given polygon, like polygon= with a Polygon argument does. This version translates the polygon from micrometer units to database units internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'polygon'. This is the setter.
The object exposes a writable attribute 'dpolygon'. This is the setter.

drectangle

Signature: *[const]* variant **drectangle**

Description: Gets the rectangle in micron units if the object represents one or nil if not

If the shape represents a rectangle - i.e. a box or box polygon, a path with two points and no round ends - this method returns the box. If not, nil is returned.

This method has been introduced in version 0.29.

dsimple_polygon

Signature: *[const]* variant **dsimple_polygon**

Description: Returns the simple polygon object in micrometer units

Returns the simple polygon object that this shape refers to or converts the object to a simple polygon. The method returns the same object than simple_polygon, but translates it to micrometer units internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'dsimple_polygon'. This is the getter.

dsimple_polygon=

Signature: void **dsimple_polygon=** (const DSimplePolygon polygon)

Description: Replaces the shape by the given simple polygon (in micrometer units)

This method replaces the shape by the given text, like simple_polygon= with a SimplePolygon argument does. This version translates the polygon from micrometer units to database units internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'simple_polygon'. This is the setter.
The object exposes a writable attribute 'dsimple_polygon'. This is the setter.

dtext

Signature: *[const]* variant **dtext**

Description: Returns the path object as a DText object in micrometer units

See text for a description of this method. This method returns the text after translation to micrometer units.

This method has been added in version 0.25.

Python specific notes:
The object exposes a readable attribute 'dtext'. This is the getter.

dtext=

Signature: void **dtext=** (const DText text)

Description: Replaces the shape by the given text (in micrometer units)

This method replaces the shape by the given text, like text= with a Text argument does. This version translates the text from micrometer units to database units internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'text'. This is the setter.

	The object exposes a writable attribute 'dtext'. This is the setter.
dup	**Signature**: *[const]* new Shape ptr **dup** **Description**: Creates a copy of self **Python specific notes:** This method also implements '__copy__' and '__deepcopy__'.
each_dedge	**(1) Signature**: *[const,iter]* DEdge **each_dedge** **Description**: Iterates over the edges of the object and returns edges in micrometer units This method iterates over all edges of polygons and simple polygons like each_edge, but will deliver edges in micrometer units. Multiplication by the database unit is done internally. This method has been introduced in version 0.25. **(2) Signature**: *[const,iter]* DEdge **each_dedge** (unsigned int contour) **Description**: Iterates over the edges of a single contour of the object and returns edges in micrometer units This method iterates over all edges of polygons and simple polygons like each_edge, but will deliver edges in micrometer units. Multiplication by the database unit is done internally. This method has been introduced in version 0.25.
each_dpoint	**Signature**: *[const,iter]* DPoint **each_dpoint** **Description**: Iterates over all points of the object and returns points in micrometer units This method iterates over all points of the object like each_point, but it returns DPoint objects that are given in micrometer units already. Multiplication with the database unit happens internally. This method has been introduced in version 0.25.
each_dpoint_hole	**Signature**: *[const,iter]* DPoint **each_dpoint_hole** (unsigned int hole_index) **Description**: Iterates over a hole contour of the object and returns points in micrometer units This method iterates over all points of the object's contour' like each_point_hole, but it returns DPoint objects that are given in micrometer units already. Multiplication with the database unit happens internally. This method has been introduced in version 0.25.
each_dpoint_hull	**Signature**: *[const,iter]* DPoint **each_dpoint_hull** **Description**: Iterates over the hull contour of the object and returns points in micrometer units This method iterates over all points of the object's contour' like each_point_hull, but it returns DPoint objects that are given in micrometer units already. Multiplication with the database unit happens internally. This method has been introduced in version 0.25.
each_edge	**(1) Signature**: *[const,iter]* Edge **each_edge** **Description**: Iterates over the edges of the object This method applies to polygons and simple polygons and delivers all edges that form the polygon's contours. Hole edges are oriented counterclockwise while hull edges are oriented clockwise.

It will throw an exception if the object is not a polygon.

(2) Signature: *[const,iter]* Edge **each_edge** (unsigned int contour)

Description: Iterates over the edges of a single contour of the object

contour: The contour number (0 for hull, 1 for first hole ...)

This method applies to polygons and simple polygons and delivers all edges that form the given contour of the polygon. The hull has contour number 0, the first hole has contour 1 etc. Hole edges are oriented counterclockwise while hull edges are oriented clockwise.

It will throw an exception if the object is not a polygon.

This method was introduced in version 0.24.

each_point

Signature: *[const,iter]* Point **each_point**

Description: Iterates over all points of the object

This method applies to paths and delivers all points of the path's center line. It will throw an exception for other objects.

each_point_hole

Signature: *[const,iter]* Point **each_point_hole** (unsigned int hole_index)

Description: Iterates over the points of a hole contour

hole: The hole index (see holes () method)

This method applies to polygons and delivers all points of the respective hole contour. It will throw an exception for other objects. Simple polygons deliver an empty sequence.

each_point_hull

Signature: *[const,iter]* Point **each_point_hull**

Description: Iterates over the hull contour of the object

This method applies to polygons and delivers all points of the polygon hull contour. It will throw an exception for other objects.

edge

Signature: *[const]* variant **edge**

Description: Returns the edge object

Starting with version 0.23, this method returns nil, if the shape does not represent an edge.

Python specific notes:
The object exposes a readable attribute 'edge'. This is the getter.

edge=

(1) Signature: void **edge=** (const Edge edge)

Description: Replaces the shape by the given edge

This method replaces the shape by the given edge. This method can only be called for editable layouts. It does not change the user properties of the shape. Calling this method will invalidate any iterators. It should not be called inside a loop iterating over shapes.

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a writable attribute 'edge'. This is the setter.

(2) Signature: void **edge=** (const DEdge edge)

Description: Replaces the shape by the given edge (in micrometer units)

This method replaces the shape by the given edge, like edge= with a Edge argument does. This version translates the edge from micrometer units to database units internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'edge'. This is the setter.
The object exposes a writable attribute 'dedge'. This is the setter.

edge_pair

Signature: *[const]* variant **edge_pair**

Description: Returns the edge pair object

This method has been introduced in version 0.26.

Python specific notes:
The object exposes a readable attribute 'edge_pair'. This is the getter.

edge_pair=

(1) Signature: void **edge_pair=** (const EdgePair edge_pair)

Description: Replaces the shape by the given edge pair

This method replaces the shape by the given edge pair. This method can only be called for editable layouts. It does not change the user properties of the shape. Calling this method will invalidate any iterators. It should not be called inside a loop iterating over shapes.

This method has been introduced in version 0.26.

Python specific notes:
The object exposes a writable attribute 'edge_pair'. This is the setter.

(2) Signature: void **edge_pair=** (const DEdgePair edge_pair)

Description: Replaces the shape by the given edge pair (in micrometer units)

This method replaces the shape by the given edge pair, like edge_pair= with a EdgePair argument does. This version translates the edge pair from micrometer units to database units internally.

This method has been introduced in version 0.26.

Python specific notes:
The object exposes a writable attribute 'edge_pair'. This is the setter.
The object exposes a writable attribute 'dedge_pair'. This is the setter.

has_prop_id?

Signature: *[const]* bool **has_prop_id?**

Description: Returns true, if the shape has properties, i.e. has a properties ID

holes

Signature: *[const]* unsigned int **holes**

Description: Returns the number of holes

This method applies to polygons and will throw an exception for other objects.. Simple polygons deliver a value of zero.

is_array_member?

Signature: *[const]* bool **is_array_member?**

Description: Returns true, if the shape is a member of a shape array

is_box?

Signature: *[const]* bool **is_box?**

Description: Returns true if the shape is a box

is_const_object?	**Signature**: *[const]* bool **is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.
is_edge?	**Signature**: *[const]* bool **is_edge?** **Description**: Returns true, if the object is an edge
is_edge_pair?	**Signature**: *[const]* bool **is_edge_pair?** **Description**: Returns true, if the object is an edge pair This method has been introduced in version 0.26.
is_null?	**Signature**: *[const]* bool **is_null?** **Description**: Returns true, if the shape reference is a null reference (not referring to a shape)
is_path?	**Signature**: *[const]* bool **is_path?** **Description**: Returns true, if the shape is a path
is_point?	**Signature**: *[const]* bool **is_point?** **Description**: Returns true, if the object is an point This method has been introduced in version 0.28.
is_polygon?	**Signature**: *[const]* bool **is_polygon?** **Description**: Returns true, if the shape is a polygon This method returns true only if the object is a polygon or a simple polygon. Other objects can convert to polygons, for example paths, so it may be possible to use the polygon method also if is_polygon? does not return true.
is_simple_polygon?	**Signature**: *[const]* bool **is_simple_polygon?** **Description**: Returns true, if the shape is a simple polygon This method returns true only if the object is a simple polygon. The simple polygon identity is contained in the polygon identity, so usually it is sufficient to use is_polygon? and polygon instead of specifically handle simply polygons. This method is provided only for specific optimisation purposes.
is_text?	**Signature**: *[const]* bool **is_text?** **Description**: Returns true, if the object is a text
is_user_object?	**Signature**: *[const]* bool **is_user_object?** **Description**: Returns true if the shape is a user defined object
is_valid?	**Signature**: *[const]* bool **is_valid?** **Description**: Returns true, if the shape is valid

After the shape is deleted, the shape object is no longer valid and this method returns false.

This method has been introduced in version 0.23.

layer

Signature: *[const]* unsigned int **layer**

Description: Returns the layer index of the layer the shape is on

Throws an exception if the shape does not reside inside a cell.

This method has been added in version 0.23.

Python specific notes:
The object exposes a readable attribute 'layer'. This is the getter.

layer=

Signature: void **layer=** (unsigned int layer_index)

Description: Moves the shape to a layer given by the layer index object

This method has been added in version 0.23.

Python specific notes:
The object exposes a writable attribute 'layer'. This is the setter.

layer_info

Signature: *[const]* LayerInfo **layer_info**

Description: Returns the LayerInfo object of the layer the shape is on

If the shape does not reside inside a cell, an empty layer is returned.

This method has been added in version 0.23.

Python specific notes:
The object exposes a readable attribute 'layer_info'. This is the getter.

layer_info=

Signature: void **layer_info=** (const LayerInfo layer_info)

Description: Moves the shape to a layer given by a LayerInfo object

If no layer with the given properties exists, an exception is thrown.

This method has been added in version 0.23.

Python specific notes:
The object exposes a writable attribute 'layer_info'. This is the setter.

layout

Signature: Layout ptr **layout**

Description: Gets a reference to the Layout the shape belongs to

This reference can be nil, if the Shape object is not living inside a layout.

This method has been introduced in version 0.22.

new

Signature: *[static]* new Shape ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

path

Signature: *[const]* variant **path**

Description: Returns the path object

Starting with version 0.23, this method returns nil, if the shape does not represent a path.

Python specific notes:

The object exposes a readable attribute 'path'. This is the getter.

path=

(1) Signature: void **path=** (const Path box)

Description: Replaces the shape by the given path object

This method replaces the shape by the given path object. This method can only be called for editable layouts. It does not change the user properties of the shape. Calling this method will invalidate any iterators. It should not be called inside a loop iterating over shapes.

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a writable attribute 'path'. This is the setter.

(2) Signature: void **path=** (const DPath path)

Description: Replaces the shape by the given path (in micrometer units)

This method replaces the shape by the given path, like path= with a Path argument does. This version translates the path from micrometer units to database units internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'path'. This is the setter.
The object exposes a writable attribute 'dpath'. This is the setter.

path_bgnext

Signature: *[const]* int **path_bgnext**

Description: Gets the path's starting vertex extension

Applies to paths only. Will throw an exception if the object is not a path.

Python specific notes:
The object exposes a readable attribute 'path_bgnext'. This is the getter.

path_bgnext=

Signature: void **path_bgnext=** (int e)

Description: Sets the path's starting vertex extension

Applies to paths only. Will throw an exception if the object is not a path.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'path_bgnext'. This is the setter.

path_dbgnext

Signature: *[const]* double **path_dbgnext**

Description: Gets the path's starting vertex extension in micrometer units

Applies to paths only. Will throw an exception if the object is not a path.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a readable attribute 'path_dbgnext'. This is the getter.

path_dbgnext=

Signature: void **path_dbgnext=** (double e)

Description: Sets the path's starting vertex extension in micrometer units

Applies to paths only. Will throw an exception if the object is not a path.

This method has been introduced in version 0.25.

Python specific notes:

	The object exposes a writable attribute 'path_dbgnext'. This is the setter.
path_dendext	**Signature**: *[const]* double **path_dendext** **Description**: Gets the path's end vertex extension in micrometer units Applies to paths only. Will throw an exception if the object is not a path. This method has been introduced in version 0.25. **Python specific notes:** The object exposes a readable attribute 'path_dendext'. This is the getter.
path_dendext=	**Signature**: void **path_dendext=** (double e) **Description**: Sets the path's end vertex extension in micrometer units Applies to paths only. Will throw an exception if the object is not a path. This method has been introduced in version 0.25. **Python specific notes:** The object exposes a writable attribute 'path_dendext'. This is the setter.
path_dlength	**Signature**: *[const]* double **path_dlength** **Description**: Returns the length of the path in micrometer units Applies to paths only. Will throw an exception if the object is not a path. This method returns the length of the spine plus extensions if present. The value returned is given in micrometer units. This method has been added in version 0.25.
path_dwidth	**Signature**: *[const]* double **path_dwidth** **Description**: Gets the path width in micrometer units Applies to paths only. Will throw an exception if the object is not a path. This method has been introduced in version 0.25. **Python specific notes:** The object exposes a readable attribute 'path_dwidth'. This is the getter.
path_dwidth=	**Signature**: void **path_dwidth=** (double w) **Description**: Sets the path width in micrometer units Applies to paths only. Will throw an exception if the object is not a path. Conversion to database units is done internally. This method has been introduced in version 0.25. **Python specific notes:** The object exposes a writable attribute 'path_dwidth'. This is the setter.
path_endext	**Signature**: *[const]* int **path_endext** **Description**: Obtain the path's end vertex extension Applies to paths only. Will throw an exception if the object is not a path. **Python specific notes:** The object exposes a readable attribute 'path_endext'. This is the getter.
path_endext=	**Signature**: void **path_endext=** (int e)

Description: Sets the path's end vertex extension

Applies to paths only. Will throw an exception if the object is not a path.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'path_endext'. This is the setter.

path_length

Signature: *[const]* int **path_length**

Description: Returns the length of the path

Applies to paths only. Will throw an exception if the object is not a path. This method returns the length of the spine plus extensions if present.

This method has been added in version 0.23.

path_width

Signature: *[const]* int **path_width**

Description: Gets the path width

Applies to paths only. Will throw an exception if the object is not a path.

Python specific notes:
The object exposes a readable attribute 'path_width'. This is the getter.

path_width=

Signature: void **path_width=** (int w)

Description: Sets the path width

Applies to paths only. Will throw an exception if the object is not a path.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'path_width'. This is the setter.

perimeter

Signature: *[const]* unsigned long **perimeter**

Description: Returns the perimeter of the shape

This method will return an approximation of the perimeter for paths.

This method has been added in version 0.23.

point

Signature: *[const]* variant **point**

Description: Returns the point object

This method has been introduced in version 0.28.

Python specific notes:
The object exposes a readable attribute 'point'. This is the getter.

point=

(1) Signature: void **point=** (const Point point)

Description: Replaces the shape by the given point

This method replaces the shape by the given point. This method can only be called for editable layouts. It does not change the user properties of the shape. Calling this method will invalidate any iterators. It should not be called inside a loop iterating over shapes.

This method has been introduced in version 0.28.

Python specific notes:
The object exposes a writable attribute 'point'. This is the setter.

(2) Signature: void **point=** (const DPoint point)

Description: Replaces the shape by the given point (in micrometer units)

This method replaces the shape by the given point, like point= with a Point argument does. This version translates the point from micrometer units to database units internally.

This method has been introduced in version 0.28.

Python specific notes:
The object exposes a writable attribute 'point'. This is the setter.
The object exposes a writable attribute 'dpoint'. This is the setter.

polygon

Signature: *[const]* variant **polygon**

Description: Returns the polygon object

Returns the polygon object that this shape refers to or converts the object to a polygon. Paths, boxes and simple polygons are converted to polygons. For paths this operation renders the path's hull contour.

Starting with version 0.23, this method returns nil, if the shape does not represent a geometrical primitive that can be converted to a polygon.

Python specific notes:
The object exposes a readable attribute 'polygon'. This is the getter.

polygon=

(1) Signature: void **polygon=** (const Polygon box)

Description: Replaces the shape by the given polygon object

This method replaces the shape by the given polygon object. This method can only be called for editable layouts. It does not change the user properties of the shape. Calling this method will invalidate any iterators. It should not be called inside a loop iterating over shapes.

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a writable attribute 'polygon'. This is the setter.

(2) Signature: void **polygon=** (const DPolygon polygon)

Description: Replaces the shape by the given polygon (in micrometer units)

This method replaces the shape by the given polygon, like polygon= with a Polygon argument does. This version translates the polygon from micrometer units to database units internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'polygon'. This is the setter.
The object exposes a writable attribute 'dpolygon'. This is the setter.

prop_id

Signature: *[const]* unsigned long **prop_id**

Description: Gets the properties ID associated with the shape

The Layout object can be used to retrieve the actual properties associated with the ID.

Python specific notes:
The object exposes a readable attribute 'prop_id'. This is the getter.

prop_id=

Signature: void **prop_id=** (unsigned long id)

Description: Sets the properties ID of this shape

The Layout object can be used to retrieve an ID for a given set of properties. Calling this method will invalidate any iterators. It should not be called inside a loop iterating over shapes.

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a writable attribute 'prop_id'. This is the setter.

property

Signature: *[const]* variant **property** (variant key)

Description: Gets the user property with the given key

This method is a convenience method that gets the property with the given key. If no property with that key does not exist, it will return nil. Using that method is more convenient than using the layout object and the properties ID to retrieve the property value. This method has been introduced in version 0.22.

rectangle

Signature: *[const]* variant **rectangle**

Description: Gets the rectangle if the object represents one or nil if not

If the shape represents a rectangle - i.e. a box or box polygon, a path with two points and no round ends - this method returns the box. If not, nil is returned.

This method has been introduced in version 0.29.

round_path=

Signature: void **round_path=** (bool r)

Description: The path will be a round-ended path if this property is set to true

Applies to paths only. Will throw an exception if the object is not a path. Please note that the extensions will apply as well. To get a path with circular ends, set the begin and end extensions to half the path's width.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'round_path'. This is the setter.

round_path?

Signature: *[const]* bool **round_path?**

Description: Returns true, if the path has round ends

Applies to paths only. Will throw an exception if the object is not a path.

Python specific notes:
The object exposes a readable attribute 'round_path'. This is the getter.

set_property

Signature: void **set_property** (variant key, variant value)

Description: Sets the user property with the given key to the given value

This method is a convenience method that sets the property with the given key to the given value. If no property with that key exists, it will create one. Using that method is more convenient than creating a new property set with a new ID and assigning that properties ID. This method may change the properties ID. Note: GDS only supports integer keys. OASIS supports numeric and string keys. Calling this method will invalidate any iterators. It should not be called inside a loop iterating over shapes.

This method has been introduced in version 0.22.

shapes

Signature: Shapes ptr **shapes**

Description: Gets a reference to the Shapes container the shape lives in

This reference can be nil, if the Shape object is not referring to an actual shape.

This method has been introduced in version 0.22.

simple_polygon

Signature: *[const]* variant **simple_polygon**

Description: Returns the simple polygon object

Returns the simple polygon object that this shape refers to or converts the object to a simple polygon. Paths, boxes and polygons are converted to simple polygons. Polygons with holes will have their holes removed but introducing cut lines that connect the hole contours with the outer contour. Starting with version 0.23, this method returns nil, if the shape does not represent a geometrical primitive that can be converted to a simple polygon.

Python specific notes:
The object exposes a readable attribute 'simple_polygon'. This is the getter.

simple_polygon=

(1) Signature: void **simple_polygon=** (const SimplePolygon polygon)

Description: Replaces the shape by the given simple polygon object

This method replaces the shape by the given simple polygon object. This method can only be called for editable layouts. It does not change the user properties of the shape. Calling this method will invalidate any iterators. It should not be called inside a loop iterating over shapes.

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a writable attribute 'simple_polygon'. This is the setter.

(2) Signature: void **simple_polygon=** (const DSimplePolygon polygon)

Description: Replaces the shape by the given simple polygon (in micrometer units)

This method replaces the shape by the given text, like simple_polygon= with a SimplePolygon argument does. This version translates the polygon from micrometer units to database units internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'simple_polygon'. This is the setter.
The object exposes a writable attribute 'dsimple_polygon'. This is the setter.

t_box

Signature: *[static]* int **t_box**

Description:

Use of this method is deprecated. Use TBox instead

Python specific notes:
The object exposes a readable attribute 'TBox'. This is the getter.

t_box_array

Signature: *[static]* int **t_box_array**

Description:

Use of this method is deprecated. Use TBoxArray instead

Python specific notes:
The object exposes a readable attribute 'TBoxArray'. This is the getter.

t_box_array_member

Signature: *[static]* int **t_box_array_member**

Description:

Use of this method is deprecated. Use TBoxArrayMember instead

Python specific notes:
The object exposes a readable attribute 'TBoxArrayMember'. This is the getter.

t_edge

Signature: *[static]* int **t_edge**

Description:

Use of this method is deprecated. Use TEdge instead

Python specific notes:
The object exposes a readable attribute 'TEdge'. This is the getter.

t_edge_pair

Signature: *[static]* int **t_edge_pair**

Description:

Use of this method is deprecated. Use TEdgePair instead

Python specific notes:
The object exposes a readable attribute 'TEdgePair'. This is the getter.

t_null

Signature: *[static]* int **t_null**

Description:

Use of this method is deprecated. Use TNull instead

Python specific notes:
The object exposes a readable attribute 'TNull'. This is the getter.

t_path

Signature: *[static]* int **t_path**

Description:

Use of this method is deprecated. Use TPath instead

Python specific notes:
The object exposes a readable attribute 'TPath'. This is the getter.

t_path_ptr_array

Signature: *[static]* int **t_path_ptr_array**

Description:

Use of this method is deprecated. Use TPathPtrArray instead

Python specific notes:
The object exposes a readable attribute 'TPathPtrArray'. This is the getter.

t_path_ptr_array_member

Signature: *[static]* int **t_path_ptr_array_member**

Description:

Use of this method is deprecated. Use TPathPtrArrayMember instead

Python specific notes:
The object exposes a readable attribute 'TPathPtrArrayMember'. This is the getter.

t_path_ref

Signature: *[static]* int **t_path_ref**

Description:

Use of this method is deprecated. Use TPathRef instead

Python specific notes:
The object exposes a readable attribute 'TPathRef'. This is the getter.

t_point

Signature: *[static]* int **t_point**

Description:

Use of this method is deprecated. Use TPoint instead

Python specific notes:
The object exposes a readable attribute 'TPoint'. This is the getter.

t_polygon

Signature: *[static]* int **t_polygon**

Description:

Use of this method is deprecated. Use TPolygon instead

Python specific notes:
The object exposes a readable attribute 'TPolygon'. This is the getter.

t_polygon_ptr_array

Signature: *[static]* int **t_polygon_ptr_array**

Description:

Use of this method is deprecated. Use TPolygonPtrArray instead

Python specific notes:
The object exposes a readable attribute 'TPolygonPtrArray'. This is the getter.

t_polygon_ptr_array_member

Signature: *[static]* int **t_polygon_ptr_array_member**

Description:

Use of this method is deprecated. Use TPolygonPtrArrayMember instead

Python specific notes:
The object exposes a readable attribute 'TPolygonPtrArrayMember'. This is the getter.

t_polygon_ref

Signature: *[static]* int **t_polygon_ref**

Description:

Use of this method is deprecated. Use TPolygonRef instead

Python specific notes:
The object exposes a readable attribute 'TPolygonRef'. This is the getter.

t_short_box

Signature: *[static]* int **t_short_box**

Description:

Use of this method is deprecated. Use TShortBox instead

Python specific notes:
The object exposes a readable attribute 'TShortBox'. This is the getter.

t_short_box_array

Signature: *[static]* int **t_short_box_array**

Description:

Use of this method is deprecated. Use TShortBoxArray instead

Python specific notes:
The object exposes a readable attribute 'TShortBoxArray'. This is the getter.

t_short_box_array_member

Signature: *[static]* int **t_short_box_array_member**

Description:

Use of this method is deprecated. Use TShortBoxArrayMember instead

Python specific notes:
The object exposes a readable attribute 'TShortBoxArrayMember'. This is the getter.

t_simple_polygon

Signature: *[static]* int **t_simple_polygon**

Description:

Use of this method is deprecated. Use TSimplePolygon instead

Python specific notes:
The object exposes a readable attribute 'TSimplePolygon'. This is the getter.

t_simple_polygon_ptr_array

Signature: *[static]* int **t_simple_polygon_ptr_array**

Description:

Use of this method is deprecated. Use TSimplePolygonPtrArray instead

Python specific notes:
The object exposes a readable attribute 'TSimplePolygonPtrArray'. This is the getter.

t_simple_polygon_ptr_array

Signature: *[static]* int **t_simple_polygon_ptr_array_member**

Description:

Use of this method is deprecated. Use TSimplePolygonPtrArrayMember instead

Python specific notes:
The object exposes a readable attribute 'TSimplePolygonPtrArrayMember'. This is the getter.

t_simple_polygon_ref

Signature: *[static]* int **t_simple_polygon_ref**

Description:

Use of this method is deprecated. Use TSimplePolygonRef instead

Python specific notes:
The object exposes a readable attribute 'TSimplePolygonRef'. This is the getter.

t_text

Signature: *[static]* int **t_text**

Description:

Use of this method is deprecated. Use TText instead

Python specific notes:
The object exposes a readable attribute 'TText'. This is the getter.

t_text_ptr_array

Signature: *[static]* int **t_text_ptr_array**

Description:

Use of this method is deprecated. Use TTextPtrArray instead

Python specific notes:
The object exposes a readable attribute 'TTextPtrArray'. This is the getter.

t_text_ptr_array_member

Signature: *[static]* int **t_text_ptr_array_member**

Description:

Use of this method is deprecated. Use TTextPtrArrayMember instead

Python specific notes:
The object exposes a readable attribute 'TTextPtrArrayMember'. This is the getter.

t_text_ref

Signature: *[static]* int **t_text_ref**

Description:

Use of this method is deprecated. Use TTextRef instead

Python specific notes:
The object exposes a readable attribute 'TTextRef'. This is the getter.

t_user_object

Signature: *[static]* int **t_user_object**

Description:

Use of this method is deprecated. Use TUserObject instead

Python specific notes:
The object exposes a readable attribute 'TUserObject'. This is the getter.

text

Signature: *[const]* variant **text**

Description: Returns the text object

Starting with version 0.23, this method returns nil, if the shape does not represent a text.

Python specific notes:
The object exposes a readable attribute 'text'. This is the getter.

text=

(1) Signature: void **text=** (const Text box)

Description: Replaces the shape by the given text object

This method replaces the shape by the given text object. This method can only be called for editable layouts. It does not change the user properties of the shape. Calling this method will invalidate any iterators. It should not be called inside a loop iterating over shapes.

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a writable attribute 'text'. This is the setter.

(2) Signature: void **text=** (const DText text)

Description: Replaces the shape by the given text (in micrometer units)

This method replaces the shape by the given text, like text= with a Text argument does. This version translates the text from micrometer units to database units internally.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'text'. This is the setter.
The object exposes a writable attribute 'dtext'. This is the setter.

text_dpos

Signature: *[const]* DVector **text_dpos**

Description: Gets the text's position in micrometer units

Applies to texts only. Will throw an exception if the object is not a text.

This method has been added in version 0.25.

Python specific notes:
The object exposes a readable attribute 'text_dpos'. This is the getter.

text_dpos=

Signature: void **text_dpos=** (const DVector p)

Description: Sets the text's position in micrometer units

Applies to texts only. Will throw an exception if the object is not a text.

This method has been added in version 0.25.

Python specific notes:
The object exposes a writable attribute 'text_pos'. This is the setter.

	The object exposes a writable attribute 'text_dpos'. This is the setter.
text_dsize	**Signature**: *[const]* double **text_dsize** **Description**: Gets the text size in micrometer units Applies to texts only. Will throw an exception if the object is not a text. This method has been introduced in version 0.25. **Python specific notes:** The object exposes a readable attribute 'text_dsize'. This is the getter.
text_dsize=	**Signature**: void **text_dsize=** (double size) **Description**: Sets the text size in micrometer units Applies to texts only. Will throw an exception if the object is not a text. This method has been introduced in version 0.25. **Python specific notes:** The object exposes a writable attribute 'text_dsize'. This is the setter.
text_dtrans	**Signature**: *[const]* DTrans **text_dtrans** **Description**: Gets the text transformation in micrometer units Applies to texts only. Will throw an exception if the object is not a text. This method has been added in version 0.25. **Python specific notes:** The object exposes a readable attribute 'text_dtrans'. This is the getter.
text_dtrans=	**Signature**: void **text_dtrans=** (const DTrans trans) **Description**: Sets the text transformation in micrometer units Applies to texts only. Will throw an exception if the object is not a text. This method has been introduced in version 0.25. **Python specific notes:** The object exposes a writable attribute 'text_trans'. This is the setter. The object exposes a writable attribute 'text_dtrans'. This is the setter.
text_font	**Signature**: *[const]* int **text_font** **Description**: Gets the text's font Applies to texts only. Will throw an exception if the object is not a text. **Python specific notes:** The object exposes a readable attribute 'text_font'. This is the getter.
text_font=	**Signature**: void **text_font=** (int font) **Description**: Sets the text's font Applies to texts only. Will throw an exception if the object is not a text. This method has been introduced in version 0.23. **Python specific notes:** The object exposes a writable attribute 'text_font'. This is the setter.

text_halign

Signature: *[const]* int **text_halign**

Description: Gets the text's horizontal alignment

Applies to texts only. Will throw an exception if the object is not a text. The return value is 0 for left alignment, 1 for center alignment and 2 to right alignment.

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'text_halign'. This is the getter.

text_halign=

Signature: void **text_halign=** (int a)

Description: Sets the text's horizontal alignment

Applies to texts only. Will throw an exception if the object is not a text. See text_halign for a description of that property.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'text_halign'. This is the setter.

text_pos

Signature: *[const]* Vector **text_pos**

Description: Gets the text's position

Applies to texts only. Will throw an exception if the object is not a text.

Python specific notes:
The object exposes a readable attribute 'text_pos'. This is the getter.

text_pos=

(1) Signature: void **text_pos=** (const Vector p)

Description: Sets the text's position

Applies to texts only. Will throw an exception if the object is not a text.

Python specific notes:
The object exposes a writable attribute 'text_pos'. This is the setter.

(2) Signature: void **text_pos=** (const DVector p)

Description: Sets the text's position in micrometer units

Applies to texts only. Will throw an exception if the object is not a text.

This method has been added in version 0.25.

Python specific notes:
The object exposes a writable attribute 'text_pos'. This is the setter.
The object exposes a writable attribute 'text_dpos'. This is the setter.

text_rot

Signature: *[const]* int **text_rot**

Description: Gets the text's orientation code (see Trans)

Applies to texts only. Will throw an exception if the object is not a text.

Python specific notes:
The object exposes a readable attribute 'text_rot'. This is the getter.

text_rot=

Signature: void **text_rot=** (int o)

Description: Sets the text's orientation code (see Trans)

Applies to texts only. Will throw an exception if the object is not a text.

Python specific notes:
The object exposes a writable attribute 'text_rot'. This is the setter.

text_size

Signature: *[const]* int **text_size**

Description: Gets the text size

Applies to texts only. Will throw an exception if the object is not a text.

Python specific notes:
The object exposes a readable attribute 'text_size'. This is the getter.

text_size=

Signature: void **text_size=** (int size)

Description: Sets the text size

Applies to texts only. Will throw an exception if the object is not a text.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'text_size'. This is the setter.

text_string

Signature: *[const]* string **text_string**

Description: Obtain the text string

Applies to texts only. Will throw an exception if the object is not a text.

Python specific notes:
The object exposes a readable attribute 'text_string'. This is the getter.

text_string=

Signature: void **text_string=** (string string)

Description: Sets the text string

Applies to texts only. Will throw an exception if the object is not a text.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'text_string'. This is the setter.

text_trans

Signature: *[const]* Trans **text_trans**

Description: Gets the text transformation

Applies to texts only. Will throw an exception if the object is not a text.

Python specific notes:
The object exposes a readable attribute 'text_trans'. This is the getter.

text_trans=

(1) Signature: void **text_trans=** (const Trans trans)

Description: Sets the text transformation

Applies to texts only. Will throw an exception if the object is not a text.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'text_trans'. This is the setter.

(2) Signature: void **text_trans=** (const DTrans trans)

Description: Sets the text transformation in micrometer units

Applies to texts only. Will throw an exception if the object is not a text.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'text_trans'. This is the setter.
The object exposes a writable attribute 'text_dtrans'. This is the setter.

text_valign

Signature: *[const]* int **text_valign**

Description: Gets the text's vertical alignment

Applies to texts only. Will throw an exception if the object is not a text. The return value is 0 for top alignment, 1 for center alignment and 2 to bottom alignment.

This method has been introduced in version 0.22.

Python specific notes:
The object exposes a readable attribute 'text_valign'. This is the getter.

text_valign=

Signature: void **text_valign=** (int a)

Description: Sets the text's vertical alignment

Applies to texts only. Will throw an exception if the object is not a text. See text_valign for a description of that property.

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'text_valign'. This is the setter.

to_s

Signature: *[const]* string **to_s**

Description: Create a string showing the contents of the reference

This method has been introduced with version 0.16.

Python specific notes:
This method is also available as 'str(object)'.

transform

(1) Signature: void **transform** (const Trans trans)

Description: Transforms the shape with the given transformation

This method has been introduced in version 0.23.

(2) Signature: void **transform** (const DTrans trans)

Description: Transforms the shape with the given transformation, given in micrometer units

This method has been introduced in version 0.25.

(3) Signature: void **transform** (const ICplxTrans trans)

Description: Transforms the shape with the given complex transformation

This method has been introduced in version 0.23.

(4) Signature: void **transform** (const DCplxTrans trans)

Description: Transforms the shape with the given complex transformation, given in micrometer units

This method has been introduced in version 0.25.

type

Signature: *[const]* int **type**

Description: Return the type of the shape

The returned values are the t_... constants available through the corresponding class members.

4.95. API reference - Class ShapeProcessor

Notation used in Ruby API documentation

Module: db

Description: The shape processor (boolean, sizing, merge on shapes)

The shape processor implements the boolean and edge set operations (size, merge). Because the shape processor might allocate resources which can be reused in later operations, it is implemented as an object that can be used several times. The shape processor is similar to the EdgeProcessor. The latter is specialized on handling polygons and edges directly.

Public constructors

new ShapeProcessor ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const ShapeProcessor other)	Assigns another object to self
	void	**boolean**	(const Layout layout_a, const Cell cell_a, unsigned int layer_a, const Layout layout_b, const Cell cell_b, unsigned int layer_b, Shapes out, int mode, bool hierarchical, bool resolve_holes, bool min_coherence)	Boolean operation on shapes from layouts
	Edge[]	**boolean**	(Shape[] in_a, CplxTrans[] trans_a, Shape[] in_b, CplxTrans[] trans_b, int mode)	Boolean operation on two given shape sets into an edge set
	Edge[]	**boolean**	(Shape[] in_a, Shape[] in_b, int mode)	Boolean operation on two given shape sets into an edge set

	Polygon[]	**boolean_to_polygo**	(Shape[] in_a, CplxTrans[] trans_a, Shape[] in_b, CplxTrans[] trans_b, int mode, bool resolve_holes, bool min_coherence)	Boolean operation on two given shape sets into a polygon set
	Polygon[]	**boolean_to_polygon**	(Shape[] in_a, Shape[] in_b, int mode, bool resolve_holes, bool min_coherence)	Boolean operation on two given shape sets into a polygon set
[const]	new ShapeProcessor ptr	**dup**		Creates a copy of self
	void	**merge**	(const Layout layout, const Cell cell, unsigned int layer, Shapes out, bool hierarchical, unsigned int min_wc, bool resolve_holes, bool min_coherence)	Merge the given shapes from a layout into a shapes container
	Edge[]	**merge**	(Shape[] in, CplxTrans[] trans, unsigned int min_wc)	Merge the given shapes
	Edge[]	**merge**	(Shape[] in, unsigned int min_wc)	Merge the given shapes
	Polygon[]	**merge_to_polygon**	(Shape[] in, CplxTrans[] trans, unsigned int min_wc, bool resolve_holes, bool min_coherence)	Merge the given shapes
	Polygon[]	**merge_to_polygon**	(Shape[] in, unsigned int min_wc, bool resolve_holes, bool min_coherence)	Merge the given shapes
	void	**size**	(const Layout layout, const Cell cell, unsigned int layer, Shapes out, int dx, int dy, unsigned int mode, bool hierarchical, bool resolve_holes, bool min_coherence)	Sizing operation on shapes from layouts
	void	**size**	(const Layout layout, const Cell cell, unsigned int layer, Shapes out,	Sizing operation on shapes from layouts

		int d, unsigned int mode, bool hierarchical, bool resolve_holes, bool min_coherence)	
Edge[]	size	(Shape[] in, CplxTrans[] trans, int d, unsigned int mode)	Size the given shapes
Edge[]	size	(Shape[] in, CplxTrans[] trans, int dx, int dy, unsigned int mode)	Size the given shapes
Edge[]	size	(Shape[] in, int d, unsigned int mode)	Size the given shapes
Edge[]	size	(Shape[] in, int dx, int dy, unsigned int mode)	Size the given shapes
Polygon[]	size_to_polygon	(Shape[] in, CplxTrans[] trans, int d, unsigned int mode, bool resolve_holes, bool min_coherence)	Size the given shapes
Polygon[]	size_to_polygon	(Shape[] in, CplxTrans[] trans, int dx, int dy, unsigned int mode, bool resolve_holes, bool min_coherence)	Size the given shapes
Polygon[]	size_to_polygon	(Shape[] in, int d, unsigned int mode, bool resolve_holes, bool min_coherence)	Size the given shapes
Polygon[]	size_to_polygon	(Shape[] in, int dx, int dy, unsigned int mode, bool resolve_holes, bool min_coherence)	Size the given shapes

Deprecated methods (protected, public, static, non-static and constructors)

void	create	Use of this method is deprecated. Use _create instead
void	destroy	Use of this method is deprecated. Use _destroy instead

[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const ShapeProcessor other)

Description: Assigns another object to self

boolean

(1) Signature: void **boolean** (const Layout layout_a, const Cell cell_a, unsigned int layer_a, const Layout layout_b, const Cell cell_b, unsigned int layer_b, Shapes out, int mode, bool hierarchical, bool resolve_holes, bool min_coherence)

Description: Boolean operation on shapes from layouts

layout_a:	The layout from which to take the shapes for input A
cell_a:	The cell (in 'layout') from which to take the shapes for input A
layer_a:	The cell (in 'layout') from which to take the shapes for input A
layout_b:	The layout from which to take the shapes for input B
cell_b:	The cell (in 'layout') from which to take the shapes for input B
layer_b:	The cell (in 'layout') from which to take the shapes for input B
out:	The shapes container where to put the shapes into (is cleared before)
mode:	The boolean operation (see EdgeProcessor)
hierarchical:	Collect shapes from sub cells as well
resolve_holes:	true, if holes should be resolved into the hull
min_coherence:	true, if minimum polygons should be created for touching corners

See the EdgeProcessor for a description of the boolean operations. This implementation takes shapes from layout cells (optionally all in hierarchy) and produces new shapes in a shapes container.

(2) Signature: Edge[] **boolean** (Shape[] in_a, CplxTrans[] trans_a, Shape[] in_b, CplxTrans[] trans_b, int mode)

Description: Boolean operation on two given shape sets into an edge set

in_a:	The set of shapes to use for input A
trans_a:	A set of transformations to apply before the shapes are used
in_b:	The set of shapes to use for input A
trans_b:	A set of transformations to apply before the shapes are used
mode:	The boolean operation (see EdgeProcessor)

See the EdgeProcessor for a description of the boolean operations. This implementation takes shapes rather than polygons for input and produces an edge set.

(3) Signature: Edge[] **boolean** (Shape[] in_a, Shape[] in_b, int mode)

Description: Boolean operation on two given shape sets into an edge set

in_a:	The set of shapes to use for input A
in_b:	The set of shapes to use for input A
mode:	The boolean operation (see EdgeProcessor)

See the EdgeProcessor for a description of the boolean operations. This implementation takes shapes rather than polygons for input and produces an edge set.

This version does not feature a transformation for each shape (unity is assumed).

boolean_to_polygon

(1) Signature: Polygon[] **boolean_to_polygon** (Shape[] in_a, CplxTrans[] trans_a, Shape[] in_b, CplxTrans[] trans_b, int mode, bool resolve_holes, bool min_coherence)

Description: Boolean operation on two given shape sets into a polygon set

in_a:	The set of shapes to use for input A
trans_a:	A set of transformations to apply before the shapes are used
in_b:	The set of shapes to use for input A
trans_b:	A set of transformations to apply before the shapes are used
mode:	The boolean operation (see EdgeProcessor)
resolve_holes:	true, if holes should be resolved into the hull
min_coherence:	true, if minimum polygons should be created for touching corners

See the EdgeProcessor for a description of the boolean operations. This implementation takes shapes rather than polygons for input and produces a polygon set.

(2) Signature: Polygon[] **boolean_to_polygon** (Shape[] in_a, Shape[] in_b, int mode, bool resolve_holes, bool min_coherence)

Description: Boolean operation on two given shape sets into a polygon set

in_a:	The set of shapes to use for input A
in_b:	The set of shapes to use for input A
mode:	The boolean operation (see EdgeProcessor)
resolve_holes:	true, if holes should be resolved into the hull
min_coherence:	true, if minimum polygons should be created for touching corners

See the EdgeProcessor for a description of the boolean operations. This implementation takes shapes rather than polygons for input and produces a polygon set.

This version does not feature a transformation for each shape (unity is assumed).

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new ShapeProcessor ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

merge

(1) Signature: void **merge** (const Layout layout, const Cell cell, unsigned int layer, Shapes out, bool hierarchical, unsigned int min_wc, bool resolve_holes, bool min_coherence)

Description: Merge the given shapes from a layout into a shapes container

layout:	The layout from which to take the shapes
cell:	The cell (in 'layout') from which to take the shapes
layer:	The cell (in 'layout') from which to take the shapes
out:	The shapes container where to put the shapes into (is cleared before)
hierarchical:	Collect shapes from sub cells as well
min_wc:	The minimum wrap count for output (0: all polygons, 1: at least two overlapping)
resolve_holes:	true, if holes should be resolved into the hull
min_coherence:	true, if minimum polygons should be created for touching corners

See the EdgeProcessor for a description of the merge method. This implementation takes shapes from a layout cell (optionally all in hierarchy) and produces new shapes in a shapes container.

(2) Signature: Edge[] **merge** (Shape[] in, CplxTrans[] trans, unsigned int min_wc)

Description: Merge the given shapes

in:	The set of shapes to merge
trans:	A corresponding set of transformations to apply on the shapes
min_wc:	The minimum wrap count for output (0: all polygons, 1: at least two overlapping)

See the EdgeProcessor for a description of the merge method. This implementation takes shapes rather than polygons for input and produces an edge set.

(3) Signature: Edge[] **merge** (Shape[] in, unsigned int min_wc)

Description: Merge the given shapes

in:	The set of shapes to merge
min_wc:	The minimum wrap count for output (0: all polygons, 1: at least two overlapping)

See the EdgeProcessor for a description of the merge method. This implementation takes shapes rather than polygons for input and produces an edge set.

This version does not feature a transformation for each shape (unity is assumed).

merge_to_polygon

(1) Signature: Polygon[] **merge_to_polygon** (Shape[] in, CplxTrans[] trans, unsigned int min_wc, bool resolve_holes, bool min_coherence)

Description: Merge the given shapes

in:	The set of shapes to merge
trans:	A corresponding set of transformations to apply on the shapes
min_wc:	The minimum wrap count for output (0: all polygons, 1: at least two overlapping)
resolve_holes:	true, if holes should be resolved into the hull
min_coherence:	true, if minimum polygons should be created for touching corners

See the EdgeProcessor for a description of the merge method. This implementation takes shapes rather than polygons for input and produces a polygon set.

(2) Signature: Polygon[] **merge_to_polygon** (Shape[] in, unsigned int min_wc, bool resolve_holes, bool min_coherence)

Description: Merge the given shapes

in:	The set of shapes to merge
min_wc:	The minimum wrap count for output (0: all polygons, 1: at least two overlapping)
resolve_holes:	true, if holes should be resolved into the hull
min_coherence:	true, if minimum polygons should be created for touching corners

See the EdgeProcessor for a description of the merge method. This implementation takes shapes rather than polygons for input and produces a polygon set.

This version does not feature a transformation for each shape (unity is assumed).

new

Signature: *[static]* new ShapeProcessor ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

size

(1) Signature: void **size** (const Layout layout, const Cell cell, unsigned int layer, Shapes out, int dx, int dy, unsigned int mode, bool hierarchical, bool resolve_holes, bool min_coherence)

Description: Sizing operation on shapes from layouts

layout:	The layout from which to take the shapes
cell:	The cell (in 'layout') from which to take the shapes
layer:	The cell (in 'layout') from which to take the shapes
out:	The shapes container where to put the shapes into (is cleared before)
dx:	The sizing value in x-direction (see EdgeProcessor)
dy:	The sizing value in y-direction (see EdgeProcessor)
mode:	The sizing mode (see EdgeProcessor)
hierarchical:	Collect shapes from sub cells as well
resolve_holes:	true, if holes should be resolved into the hull
min_coherence:	true, if minimum polygons should be created for touching corners

See the EdgeProcessor for a description of the sizing operation. This implementation takes shapes from a layout cell (optionally all in hierarchy) and produces new shapes in a shapes container.

(2) Signature: void **size** (const Layout layout, const Cell cell, unsigned int layer, Shapes out, int d, unsigned int mode, bool hierarchical, bool resolve_holes, bool min_coherence)

Description: Sizing operation on shapes from layouts

layout:	The layout from which to take the shapes
cell:	The cell (in 'layout') from which to take the shapes
layer:	The cell (in 'layout') from which to take the shapes
out:	The shapes container where to put the shapes into (is cleared before)
d:	The sizing value (see EdgeProcessor)
mode:	The sizing mode (see EdgeProcessor)
hierarchical:	Collect shapes from sub cells as well
resolve_holes:	true, if holes should be resolved into the hull
min_coherence:	true, if minimum polygons should be created for touching corners

See the EdgeProcessor for a description of the sizing operation. This implementation takes shapes from a layout cell (optionally all in hierarchy) and produces new shapes in a shapes container. This is the isotropic version which does not allow specification of different sizing values in x and y-direction.

(3) Signature: Edge[] **size** (Shape[] in, CplxTrans[] trans, int d, unsigned int mode)

Description: Size the given shapes

in:	The set of shapes to size
trans:	A corresponding set of transformations to apply on the shapes
d:	The sizing value
mode:	The sizing mode (see EdgeProcessor)

See the EdgeProcessor for a description of the sizing method. This implementation takes shapes rather than polygons for input and produces an edge set. This is isotropic version that does not allow to specify different values in x and y direction.

(4) Signature: Edge[] **size** (Shape[] in, CplxTrans[] trans, int dx, int dy, unsigned int mode)

Description: Size the given shapes

in:	The set of shapes to size
trans:	A corresponding set of transformations to apply on the shapes
dx:	The sizing value in x-direction
dy:	The sizing value in y-direction
mode:	The sizing mode (see EdgeProcessor)

See the EdgeProcessor for a description of the sizing method. This implementation takes shapes rather than polygons for input and produces an edge set.

(5) Signature: Edge[] **size** (Shape[] in, int d, unsigned int mode)

Description: Size the given shapes

in:	The set of shapes to size
d:	The sizing value
mode:	The sizing mode (see EdgeProcessor)

See the EdgeProcessor for a description of the sizing method. This implementation takes shapes rather than polygons for input and produces an edge set. This is isotropic version that does not allow to specify different values in x and y direction. This version does not feature a transformation for each shape (unity is assumed).

(6) Signature: Edge[] **size** (Shape[] in, int dx, int dy, unsigned int mode)

Description: Size the given shapes

in:	The set of shapes to size
dx:	The sizing value in x-direction
dy:	The sizing value in y-direction
mode:	The sizing mode (see EdgeProcessor)

See the EdgeProcessor for a description of the sizing method. This implementation takes shapes rather than polygons for input and produces an edge set.

This version does not feature a transformation for each shape (unity is assumed).

size_to_polygon

(1) Signature: Polygon[] **size_to_polygon** (Shape[] in, CplxTrans[] trans, int d, unsigned int mode, bool resolve_holes, bool min_coherence)

Description: Size the given shapes

in:	The set of shapes to size
trans:	A corresponding set of transformations to apply on the shapes
d:	The sizing value
mode:	The sizing mode (see EdgeProcessor)
resolve_holes:	true, if holes should be resolved into the hull
min_coherence:	true, if minimum polygons should be created for touching corners

See the EdgeProcessor for a description of the sizing method. This implementation takes shapes rather than polygons for input and produces a polygon set. This is isotropic version that does not allow to specify different values in x and y direction.

(2) Signature: Polygon[] **size_to_polygon** (Shape[] in, CplxTrans[] trans, int dx, int dy, unsigned int mode, bool resolve_holes, bool min_coherence)

Description: Size the given shapes

in:	The set of shapes to size
trans:	A corresponding set of transformations to apply on the shapes
dx:	The sizing value in x-direction
dy:	The sizing value in y-direction
mode:	The sizing mode (see EdgeProcessor)
resolve_holes:	true, if holes should be resolved into the hull
min_coherence:	true, if minimum polygons should be created for touching corners

See the EdgeProcessor for a description of the sizing method. This implementation takes shapes rather than polygons for input and produces a polygon set.

(3) Signature: Polygon[] **size_to_polygon** (Shape[] in, int d, unsigned int mode, bool resolve_holes, bool min_coherence)

Description: Size the given shapes

in:	The set of shapes to size

d:	The sizing value
mode:	The sizing mode (see EdgeProcessor)
resolve_holes:	true, if holes should be resolved into the hull
min_coherence:	true, if minimum polygons should be created for touching corners

See the EdgeProcessor for a description of the sizing method. This implementation takes shapes rather than polygons for input and produces a polygon set. This is isotropic version that does not allow to specify different values in x and y direction. This version does not feature a transformation for each shape (unity is assumed).

(4) Signature: Polygon[] **size_to_polygon** (Shape[] in, int dx, int dy, unsigned int mode, bool resolve_holes, bool min_coherence)

Description: Size the given shapes

in:	The set of shapes to size
dx:	The sizing value in x-direction
dy:	The sizing value in y-direction
mode:	The sizing mode (see EdgeProcessor)
resolve_holes:	true, if holes should be resolved into the hull
min_coherence:	true, if minimum polygons should be created for touching corners

See the EdgeProcessor for a description of the sizing method. This implementation takes shapes rather than polygons for input and produces a polygon set.

This version does not feature a transformation for each shape (unity is assumed).

4.96. API reference - Class Shapes

Notation used in Ruby API documentation

Module: db

Description: A collection of shapes

A shapes collection is a collection of geometrical objects, such as polygons, boxes, paths, edges, edge pairs or text objects.

Shapes objects are the basic containers for geometrical objects of a cell. Inside a cell, there is one Shapes object per layer.

Public constructors

new Shapes ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const Shapes other)	Assigns another object to self
[const]	Cell ptr	**cell**		Gets the cell the shape container belongs to
	void	**clear**		Clears the shape container
	void	**clear**	(unsigned int flags)	Clears certain shape types from the shape container
[const]	new Shapes ptr	**dup**		Creates a copy of self
[const,iter]	Shape	**each**	(unsigned int flags)	Gets all shapes
[const,ite	Shape	**each**		Gets all shapes
[const,iter]	Shape	**each_overlapping**	(unsigned int flags, const Box region)	Gets all shapes that overlap the search box (region)
[const,ite	Shape	**each_overlapping**	(unsigned int flags, const DBox region)	Gets all shapes that overlap the search box (region) where the search box is given in micrometer units

[const,iter]	Shape	**each_overlapping**	(const Box region)	Gets all shapes that overlap the search box (region)
[const,ite	Shape	**each_overlapping**	(const DBox region)	Gets all shapes that overlap the search box (region) where the search box is given in micrometer units
[const,iter]	Shape	**each_touching**	(unsigned int flags, const Box region)	Gets all shapes that touch the search box (region)
[const,ite	Shape	**each_touching**	(unsigned int flags, const DBox region)	Gets all shapes that touch the search box (region) where the search box is given in micrometer units
[const,iter]	Shape	**each_touching**	(const Box region)	Gets all shapes that touch the search box (region)
[const,ite	Shape	**each_touching**	(const DBox region)	Gets all shapes that touch the search box (region) where the search box is given in micrometer units
	void	**erase**	(const Shape shape)	Erases the shape pointed to by the given Shape object
[const]	Shape	**find**	(const Shape shape)	Finds a shape inside this collected
	Shape	**insert**	(const Shape shape)	Inserts a shape from a shape reference into the shapes list
	Shape	**insert**	(const Shape shape, const Trans trans)	Inserts a shape from a shape reference into the shapes list with a transformation
	Shape	**insert**	(const Shape shape, const DTrans trans)	Inserts a shape from a shape reference into the shapes list with a transformation (given in micrometer units)
	Shape	**insert**	(const Shape shape, const ICplxTrans trans)	Inserts a shape from a shape reference into the shapes list with a complex integer transformation
	Shape	**insert**	(const Shape shape, const DCplxTrans trans)	Inserts a shape from a shape reference into the shapes list with a complex integer transformation (given in micrometer units)
	void	**insert**	(const RecursiveShapeIterator iter)	Inserts the shapes taken from a recursive shape iterator
	void	**insert**	(const RecursiveShapeIterator iter, const ICplxTrans trans)	Inserts the shapes taken from a recursive shape iterator with a transformation
	void	**insert**	(const Shapes shapes)	Inserts the shapes taken from another shape container
	void	**insert**	(const Shapes shapes, const ICplxTrans trans)	Inserts the shapes taken from another shape container with a transformation
	void	**insert**	(const Shapes shapes, unsigned int flags)	Inserts the shapes taken from another shape container

void	insert	(const Shapes shapes, unsigned int flags, const ICplxTrans trans)	Inserts the shapes taken from another shape container with a transformation
void	insert	(const Region region)	Inserts the polygons from the region into this shape container
void	insert	(const Region region, const ICplxTrans trans)	Inserts the polygons from the region into this shape container with a transformation
void	insert	(const Region region, const DCplxTrans trans)	Inserts the polygons from the region into this shape container with a transformation (given in micrometer units)
void	insert	(const Edges edges)	Inserts the edges from the edge collection into this shape container
void	insert	(const Edges edges, const ICplxTrans trans)	Inserts the edges from the edge collection into this shape container with a transformation
void	insert	(const Edges edges, const DCplxTrans trans)	Inserts the edges from the edge collection into this shape container with a transformation (given in micrometer units)
void	insert	(const EdgePairs edge_pairs)	Inserts the edges from the edge pair collection into this shape container
void	insert	(const EdgePairs edge_pairs, const ICplxTrans trans)	Inserts the edge pairs from the edge pair collection into this shape container with a transformation
void	insert	(const EdgePairs edge_pairs, const DCplxTrans trans)	Inserts the edge pairs from the edge pair collection into this shape container with a transformation (given in micrometer units)
void	insert	(const Texts texts)	Inserts the texts from the text collection into this shape container
void	insert	(const Texts texts, const ICplxTrans trans)	Inserts the texts from the text collection into this shape container with a transformation
void	insert	(const Texts texts, const DCplxTrans trans)	Inserts the texts from the text collection into this shape container with a transformation (given in micrometer units)
Shape	insert	(const Box box)	Inserts a box into the shapes list
Shape	insert	(const DBox box)	Inserts a micrometer-unit box into the shapes list
Shape	insert	(const Path path)	Inserts a path into the shapes list
Shape	insert	(const DPath path)	Inserts a micrometer-unit path into the shapes list
Shape	insert	(const Edge edge)	Inserts an edge into the shapes list
Shape	insert	(const DEdge edge)	Inserts a micrometer-unit edge into the shapes list

Shape	insert	(const EdgePair edge_pair)	Inserts an edge pair into the shapes list
Shape	insert	(const DEdgePair edge_pair)	Inserts a micrometer-unit edge pair into the shapes list
Shape	insert	(const Point point)	Inserts an point into the shapes list
Shape	insert	(const DPoint point)	Inserts a micrometer-unit point into the shapes list
Shape	insert	(const Text text)	Inserts a text into the shapes list
Shape	insert	(const DText text)	Inserts a micrometer-unit text into the shapes list
Shape	insert	(const SimplePolygon simple_polygon)	Inserts a simple polygon into the shapes list
Shape	insert	(const DSimplePolygon simple_polygon)	Inserts a micrometer-unit simple polygon into the shapes list
Shape	insert	(const Polygon polygon)	Inserts a polygon into the shapes list
Shape	insert	(const DPolygon polygon)	Inserts a micrometer-unit polygon into the shapes list
Shape	insert	(const Box box, unsigned long property_id)	Inserts a box with properties into the shapes list
Shape	insert	(const DBox box, unsigned long property_id)	Inserts a micrometer-unit box with properties into the shapes list
Shape	insert	(const Path path, unsigned long property_id)	Inserts a path with properties into the shapes list
Shape	insert	(const DPath path, unsigned long property_id)	Inserts a micrometer-unit path with properties into the shapes list
Shape	insert	(const Edge edge, unsigned long property_id)	Inserts an edge with properties into the shapes list
Shape	insert	(const DEdge edge, unsigned long property_id)	Inserts a micrometer-unit edge with properties into the shapes list
Shape	insert	(const EdgePair edge_pair, unsigned long property_id)	Inserts an edge pair with properties into the shapes list
Shape	insert	(const DEdgePair edge_pair, unsigned long property_id)	Inserts a micrometer-unit edge pair with properties into the shapes list
Shape	insert	(const Text text, unsigned long property_id)	Inserts a text with properties into the shapes list
Shape	insert	(const DText text, unsigned long property_id)	Inserts a micrometer-unit text with properties into the shapes list
Shape	insert	(const SimplePolygon simple_polygon, unsigned long property_id)	Inserts a simple polygon with properties into the shapes list

	Shape	**insert**	(const DSimplePolygon simple_polygon, unsigned long property_id)	Inserts a micrometer-unit simple polygon with properties into the shapes list
	Shape	**insert**	(const Polygon polygon, unsigned long property_id)	Inserts a polygon with properties into the shapes list
	Shape	**insert**	(const DPolygon polygon, unsigned long property_id)	Inserts a micrometer-unit polygon with properties into the shapes list
	void	**insert_as_edges**	(const EdgePairs edge_pairs)	Inserts the edge pairs from the edge pair collection as individual edges into this shape container
	void	**insert_as_edges**	(const EdgePairs edge_pairs, const ICplxTrans trans)	Inserts the edge pairs from the edge pair collection as individual into this shape container with a transformation
	void	**insert_as_edges**	(const EdgePairs edge_pairs, const DCplxTrans trans)	Inserts the edge pairs from the edge pair collection as individual into this shape container with a transformation (given in micrometer units)
	void	**insert_as_polygons**	(const EdgePairs edge_pairs, int e)	Inserts the edge pairs from the edge pair collection as polygons into this shape container
	void	**insert_as_polygor**	(const EdgePairs edge_pairs, double e)	Inserts the edge pairs from the edge pair collection as polygons into this shape container
	void	**insert_as_polygons**	(const EdgePairs edge_pairs, const ICplxTrans e, int trans)	Inserts the edge pairs from the edge pair collection as polygons into this shape container with a transformation
	void	**insert_as_polygor**	(const EdgePairs edge_pairs, const DCplxTrans e, double trans)	Inserts the edge pairs from the edge pair collection as polygons into this shape container with a transformation
[const]	bool	**is_empty?**		Returns a value indicating whether the shapes container is empty
[const]	bool	**is_valid?**	(const Shape shape)	Tests if the given Shape object is still pointing to a valid object
	Layout ptr	**layout**		Gets the layout object the shape container belongs to
	Shape	**replace**	(const Shape shape, const Box box)	Replaces the given shape with a box
	Shape	**replace**	(const Shape shape, const DBox box)	Replaces the given shape with a box given in micrometer units
	Shape	**replace**	(const Shape shape, const Path path)	Replaces the given shape with a path
	Shape	**replace**	(const Shape shape, const DPath path)	Replaces the given shape with a path given in micrometer units

	Shape	**replace**	(const Shape shape, const Edge edge)	Replaces the given shape with an edge object
	Shape	**replace**	(const Shape shape, const DEdge edge)	Replaces the given shape with an edge given in micrometer units
	Shape	**replace**	(const Shape shape, const EdgePair edge_pair)	Replaces the given shape with an edge pair object
	Shape	**replace**	(const Shape shape, const DEdgePair edge_pair)	Replaces the given shape with an edge pair given in micrometer units
	Shape	**replace**	(const Shape shape, const Point point)	Replaces the given shape with an point object
	Shape	**replace**	(const Shape shape, const DPoint point)	Replaces the given shape with an point given in micrometer units
	Shape	**replace**	(const Shape shape, const Text text)	Replaces the given shape with a text object
	Shape	**replace**	(const Shape shape, const DText text)	Replaces the given shape with a text given in micrometer units
	Shape	**replace**	(const Shape shape, const SimplePolygon simple_polygon)	Replaces the given shape with a simple polygon
	Shape	**replace**	(const Shape shape, const DSimplePolygon simple_polygon)	Replaces the given shape with a simple polygon given in micrometer units
	Shape	**replace**	(const Shape shape, const Polygon polygon)	Replaces the given shape with a polygon
	Shape	**replace**	(const Shape shape, const DPolygon polygon)	Replaces the given shape with a polygon given in micrometer units
	Shape	**replace_prop_id**	(const Shape shape, unsigned long property_id)	Replaces (or install) the properties of a shape
[const]	unsigned long	**size**		Gets the number of shapes in this container
	void	**transform**	(const Trans trans)	Transforms all shapes with the given transformation
	void	**transform**	(const DTrans trans)	Transforms all shapes with the given transformation (given in micrometer units)
	void	**transform**	(const ICplxTrans trans)	Transforms all shapes with the given complex integer transformation
	void	**transform**	(const DCplxTrans trans)	Transforms all shapes with the given transformation (given in micrometer units)
	Shape	**transform**	(const Shape shape, const Trans trans)	Transforms the shape given by the reference with the given transformation

Shape	**transform**	(const Shape shape, const DTrans trans)	Transforms the shape given by the reference with the given transformation, where the transformation is given in micrometer units
Shape	**transform**	(const Shape shape, const ICplxTrans trans)	Transforms the shape given by the reference with the given complex integer space transformation
Shape	**transform**	(const Shape shape, const DCplxTrans trans)	Transforms the shape given by the reference with the given complex transformation, where the transformation is given in micrometer units

Public static methods and constants

unsigned int	**SAll**	Indicates that all shapes shall be retrieved
unsigned int	**SAllWithProperties**	Indicates that all shapes with properties shall be retrieved
unsigned int	**SBoxes**	Indicates that boxes shall be retrieved
unsigned int	**SEdgePairs**	Indicates that edge pairs shall be retrieved
unsigned int	**SEdges**	Indicates that edges shall be retrieved
unsigned int	**SPaths**	Indicates that paths shall be retrieved
unsigned int	**SPoints**	Indicates that points shall be retrieved
unsigned int	**SPolygons**	Indicates that polygons shall be retrieved
unsigned int	**SProperties**	Indicates that only shapes with properties shall be retrieved
unsigned int	**SRegions**	Indicates that objects which can be polygonized shall be retrieved (paths, boxes, polygons etc.)
unsigned int	**STexts**	Indicates that texts be retrieved
unsigned int	**SUserObjects**	Indicates that user objects shall be retrieved

Detailed description

SAll

Signature: *[static]* unsigned int **SAll**

Description: Indicates that all shapes shall be retrieved

You can use this constant to construct 'except' classes - e.g. to specify 'all shape types except boxes' use

```
SAll - SBoxes
```

Python specific notes:
The object exposes a readable attribute 'SAll'. This is the getter.

SAllWithProperties

Signature: *[static]* unsigned int **SAllWithProperties**

Description: Indicates that all shapes with properties shall be retrieved

Using this selector means to retrieve only shapes with properties.You can use this constant to construct 'except' classes - e.g. to specify 'all shape types with properties except boxes' use

```
SAllWithProperties - SBoxes
```

Python specific notes:
The object exposes a readable attribute 'SAllWithProperties'. This is the getter.

SBoxes

Signature: *[static]* unsigned int **SBoxes**

Description: Indicates that boxes shall be retrieved

Python specific notes:

	The object exposes a readable attribute 'SBoxes'. This is the getter.
SEdgePairs	**Signature**: *[static]* unsigned int **SEdgePairs** **Description**: Indicates that edge pairs shall be retrieved **Python specific notes:** The object exposes a readable attribute 'SEdgePairs'. This is the getter.
SEdges	**Signature**: *[static]* unsigned int **SEdges** **Description**: Indicates that edges shall be retrieved **Python specific notes:** The object exposes a readable attribute 'SEdges'. This is the getter.
SPaths	**Signature**: *[static]* unsigned int **SPaths** **Description**: Indicates that paths shall be retrieved **Python specific notes:** The object exposes a readable attribute 'SPaths'. This is the getter.
SPoints	**Signature**: *[static]* unsigned int **SPoints** **Description**: Indicates that points shall be retrieved This constant has been added in version 0.28. **Python specific notes:** The object exposes a readable attribute 'SPoints'. This is the getter.
SPolygons	**Signature**: *[static]* unsigned int **SPolygons** **Description**: Indicates that polygons shall be retrieved **Python specific notes:** The object exposes a readable attribute 'SPolygons'. This is the getter.
SProperties	**Signature**: *[static]* unsigned int **SProperties** **Description**: Indicates that only shapes with properties shall be retrieved You can or-combine this flag with the plain shape types to select a certain shape type, but only those shapes with properties. For example to select boxes with properties, use 'SProperties | SBoxes'. **Python specific notes:** The object exposes a readable attribute 'SProperties'. This is the getter.
SRegions	**Signature**: *[static]* unsigned int **SRegions** **Description**: Indicates that objects which can be polygonized shall be retrieved (paths, boxes, polygons etc.) This constant has been added in version 0.27. **Python specific notes:** The object exposes a readable attribute 'SRegions'. This is the getter.
STexts	**Signature**: *[static]* unsigned int **STexts** **Description**: Indicates that texts be retrieved **Python specific notes:**

The object exposes a readable attribute 'STexts'. This is the getter.

SUserObjects

Signature: *[static]* unsigned int **SUserObjects**

Description: Indicates that user objects shall be retrieved

Python specific notes:
The object exposes a readable attribute 'SUserObjects'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const Shapes other)

Description: Assigns another object to self

cell

Signature: *[const]* Cell ptr **cell**

Description: Gets the cell the shape container belongs to

This method returns nil if the shape container does not belong to a cell.

This method has been added in version 0.28.

clear

(1) Signature: void **clear**

Description: Clears the shape container

This method has been introduced in version 0.16.

(2) Signature: void **clear** (unsigned int flags)

Description: Clears certain shape types from the shape container

Only shapes matching the shape types from 'flags' are removed. 'flags' is a combination of the S... constants.

This method has been introduced in version 0.28.9.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new Shapes ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

each

(1) Signature: *[const,iter]* Shape **each** (unsigned int flags)

Description: Gets all shapes

flags: An "or"-ed combination of the S... constants

(2) Signature: *[const,iter]* Shape **each**

Description: Gets all shapes

This call is equivalent to each(SAll). This convenience method has been introduced in version 0.16

Python specific notes:
This method enables iteration of the object.

each_overlapping

(1) Signature: *[const,iter]* Shape **each_overlapping** (unsigned int flags, const Box region)

Description: Gets all shapes that overlap the search box (region)

flags: An "or"-ed combination of the S... constants

region: The rectangular search region

This method was introduced in version 0.16

(2) Signature: *[const,iter]* Shape **each_overlapping** (unsigned int flags, const DBox region)

Description: Gets all shapes that overlap the search box (region) where the search box is given in micrometer units

flags: An "or"-ed combination of the S... constants

region: The rectangular search region as a DBox object in micrometer units

This method was introduced in version 0.25

(3) Signature: *[const,iter]* Shape **each_overlapping** (const Box region)

Description: Gets all shapes that overlap the search box (region)

region: The rectangular search region

This call is equivalent to each_overlapping(SAll,region). This convenience method has been introduced in version 0.16

(4) Signature: *[const,iter]* Shape **each_overlapping** (const DBox region)

Description: Gets all shapes that overlap the search box (region) where the search box is given in micrometer units

region: The rectangular search region as a DBox object in micrometer units

This call is equivalent to each_touching(SAll,region).

This method was introduced in version 0.25

each_touching

(1) Signature: *[const,iter]* Shape **each_touching** (unsigned int flags, const Box region)

Description: Gets all shapes that touch the search box (region)

flags: An "or"-ed combination of the S... constants

region: The rectangular search region

This method was introduced in version 0.16

(2) Signature: *[const,iter]* Shape **each_touching** (unsigned int flags, const DBox region)

Description: Gets all shapes that touch the search box (region) where the search box is given in micrometer units

flags:	An "or"-ed combination of the S... constants
region:	The rectangular search region as a DBox object in micrometer units

This method was introduced in version 0.25

(3) Signature: *[const,iter]* Shape **each_touching** (const Box region)

Description: Gets all shapes that touch the search box (region)

region:	The rectangular search region

This call is equivalent to each_touching(SAll,region). This convenience method has been introduced in version 0.16

(4) Signature: *[const,iter]* Shape **each_touching** (const DBox region)

Description: Gets all shapes that touch the search box (region) where the search box is given in micrometer units

region:	The rectangular search region as a DBox object in micrometer units

This call is equivalent to each_touching(SAll,region).

This method was introduced in version 0.25

erase

Signature: void **erase** (const Shape shape)

Description: Erases the shape pointed to by the given Shape object

shape:	The shape which to destroy

This method has been introduced in version 0.16. It can only be used in editable mode. Erasing a shape will invalidate the shape reference. Access to this reference may then render invalid results.

find

Signature: *[const]* Shape **find** (const Shape shape)

Description: Finds a shape inside this collected

This method has been introduced in version 0.21. This method tries to find the given shape in this collection. The original shape may be located in another collection. If the shape is found, this method returns a reference to the shape in this collection, otherwise a null reference is returned.

insert

(1) Signature: Shape **insert** (const Shape shape)

Description: Inserts a shape from a shape reference into the shapes list

Returns:	A reference (a Shape object) to the newly created shape

This method has been introduced in version 0.16.

(2) Signature: Shape **insert** (const Shape shape, const Trans trans)

Description: Inserts a shape from a shape reference into the shapes list with a transformation

shape:	The shape to insert
trans:	The transformation to apply before the shape is inserted
Returns:	A reference (a Shape object) to the newly created shape

This method has been introduced in version 0.22.

(3) Signature: Shape **insert** (const Shape shape, const DTrans trans)

Description: Inserts a shape from a shape reference into the shapes list with a transformation (given in micrometer units)

shape:	The shape to insert
trans:	The transformation to apply before the shape is inserted (displacement in micrometers)
Returns:	A reference (a Shape object) to the newly created shape

This method has been introduced in version 0.25.

(4) Signature: Shape **insert** (const Shape shape, const ICplxTrans trans)

Description: Inserts a shape from a shape reference into the shapes list with a complex integer transformation

shape:	The shape to insert
trans:	The transformation to apply before the shape is inserted
Returns:	A reference (a Shape object) to the newly created shape

This method has been introduced in version 0.22.

(5) Signature: Shape **insert** (const Shape shape, const DCplxTrans trans)

Description: Inserts a shape from a shape reference into the shapes list with a complex integer transformation (given in micrometer units)

shape:	The shape to insert
trans:	The transformation to apply before the shape is inserted (displacement in micrometer units)
Returns:	A reference (a Shape object) to the newly created shape

This method has been introduced in version 0.25.

(6) Signature: void **insert** (const RecursiveShapeIterator iter)

Description: Inserts the shapes taken from a recursive shape iterator

iter:	The iterator from which to take the shapes from

This method iterates over all shapes from the iterator and inserts them into the container.

This method has been introduced in version 0.25.3.

(7) Signature: void **insert** (const RecursiveShapeIterator iter, const ICplxTrans trans)

Description: Inserts the shapes taken from a recursive shape iterator with a transformation

iter:	The iterator from which to take the shapes from
trans:	The transformation to apply

This method iterates over all shapes from the iterator and inserts them into the container. The given transformation is applied before the shapes are inserted.

This method has been introduced in version 0.25.3.

(8) Signature: void **insert** (const Shapes shapes)

Description: Inserts the shapes taken from another shape container

shapes:	The other container from which to take the shapes from

This method takes all shapes from the given container and inserts them into this one.

This method has been introduced in version 0.25.3.

(9) Signature: void **insert** (const Shapes shapes, const ICplxTrans trans)

Description: Inserts the shapes taken from another shape container with a transformation

shapes:	The other container from which to take the shapes from
trans:	The transformation to apply

This method takes all shapes from the given container and inserts them into this one after applying the given transformation.

This method has been introduced in version 0.25.3.

(10) Signature: void **insert** (const Shapes shapes, unsigned int flags)

Description: Inserts the shapes taken from another shape container

shapes:	The other container from which to take the shapes from
flags:	The filter flags for taking the shapes from the input container (see S... constants)

This method takes all selected shapes from the given container and inserts them into this one.

This method has been introduced in version 0.25.3.

(11) Signature: void **insert** (const Shapes shapes, unsigned int flags, const ICplxTrans trans)

Description: Inserts the shapes taken from another shape container with a transformation

shapes:	The other container from which to take the shapes from
flags:	The filter flags for taking the shapes from the input container (see S... constants)
trans:	The transformation to apply

This method takes all selected shapes from the given container and inserts them into this one after applying the given transformation.

This method has been introduced in version 0.25.3.

(12) Signature: void **insert** (const Region region)

Description: Inserts the polygons from the region into this shape container

region:	The region to insert

This method inserts all polygons from the region into this shape container.

This method has been introduced in version 0.23.

(13) Signature: void **insert** (const Region region, const ICplxTrans trans)

Description: Inserts the polygons from the region into this shape container with a transformation

region:	The region to insert
trans:	The transformation to apply

This method inserts all polygons from the region into this shape container. Before a polygon is inserted, the given transformation is applied.

This method has been introduced in version 0.23.

(14) Signature: void **insert** (const Region region, const DCplxTrans trans)

Description: Inserts the polygons from the region into this shape container with a transformation (given in micrometer units)

region: The region to insert

trans: The transformation to apply (displacement in micrometer units)

This method inserts all polygons from the region into this shape container. Before a polygon is inserted, the given transformation is applied.

This method has been introduced in version 0.25.

(15) Signature: void **insert** (const Edges edges)

Description: Inserts the edges from the edge collection into this shape container

edges: The edges to insert

This method inserts all edges from the edge collection into this shape container.

This method has been introduced in version 0.23.

(16) Signature: void **insert** (const Edges edges, const ICplxTrans trans)

Description: Inserts the edges from the edge collection into this shape container with a transformation

edges: The edges to insert

trans: The transformation to apply

This method inserts all edges from the edge collection into this shape container. Before an edge is inserted, the given transformation is applied.

This method has been introduced in version 0.23.

(17) Signature: void **insert** (const Edges edges, const DCplxTrans trans)

Description: Inserts the edges from the edge collection into this shape container with a transformation (given in micrometer units)

edges: The edges to insert

trans: The transformation to apply (displacement in micrometer units)

This method inserts all edges from the edge collection into this shape container. Before an edge is inserted, the given transformation is applied.

This method has been introduced in version 0.25.

(18) Signature: void **insert** (const EdgePairs edge_pairs)

Description: Inserts the edges from the edge pair collection into this shape container

edges: The edge pairs to insert

This method inserts all edge pairs from the edge pair collection into this shape container.

This method has been introduced in version 0.26.

(19) Signature: void **insert** (const EdgePairs edge_pairs, const ICplxTrans trans)

Description: Inserts the edge pairs from the edge pair collection into this shape container with a transformation

edges: The edge pairs to insert

trans: The transformation to apply

This method inserts all edge pairs from the edge pair collection into this shape container. Before an edge pair is inserted, the given transformation is applied.

This method has been introduced in version 0.26.

(20) Signature: void **insert** (const EdgePairs edge_pairs, const DCplxTrans trans)

Description: Inserts the edge pairs from the edge pair collection into this shape container with a transformation (given in micrometer units)

edges: The edge pairs to insert

trans: The transformation to apply (displacement in micrometer units)

This method inserts all edge pairs from the edge pair collection into this shape container. Before an edge pair is inserted, the given transformation is applied.

This method has been introduced in version 0.26.

(21) Signature: void **insert** (const Texts texts)

Description: Inserts the texts from the text collection into this shape container

texts: The texts to insert

This method inserts all texts from the text collection into this shape container.

This method has been introduced in version 0.27.

(22) Signature: void **insert** (const Texts texts, const ICplxTrans trans)

Description: Inserts the texts from the text collection into this shape container with a transformation

edges: The texts to insert

trans: The transformation to apply

This method inserts all texts from the text collection into this shape container. Before an text is inserted, the given transformation is applied.

This method has been introduced in version 0.27.

(23) Signature: void **insert** (const Texts texts, const DCplxTrans trans)

Description: Inserts the texts from the text collection into this shape container with a transformation (given in micrometer units)

edges: The text to insert

trans: The transformation to apply (displacement in micrometer units)

This method inserts all texts from the text collection into this shape container. Before an text is inserted, the given transformation is applied.

This method has been introduced in version 0.27.

(24) Signature: Shape **insert** (const Box box)

Description: Inserts a box into the shapes list

Returns: A reference to the new shape (a Shape object)

Starting with version 0.16, this method returns a reference to the newly created shape

(25) Signature: Shape **insert** (const DBox box)

Description: Inserts a micrometer-unit box into the shapes list

Returns: A reference to the new shape (a Shape object)

This method behaves like the insert version with a Box argument, except that it will internally translate the box from micrometer to database units.

This variant has been introduced in version 0.25.

(26) Signature: Shape **insert** (const Path path)

Description: Inserts a path into the shapes list

Returns: A reference to the new shape (a Shape object)

Starting with version 0.16, this method returns a reference to the newly created shape

(27) Signature: Shape **insert** (const DPath path)

Description: Inserts a micrometer-unit path into the shapes list

Returns: A reference to the new shape (a Shape object)

This method behaves like the insert version with a Path argument, except that it will internally translate the path from micrometer to database units.

This variant has been introduced in version 0.25.

(28) Signature: Shape **insert** (const Edge edge)

Description: Inserts an edge into the shapes list

Starting with version 0.16, this method returns a reference to the newly created shape

(29) Signature: Shape **insert** (const DEdge edge)

Description: Inserts a micrometer-unit edge into the shapes list

Returns: A reference to the new shape (a Shape object)

This method behaves like the insert version with a Edge argument, except that it will internally translate the edge from micrometer to database units.

This variant has been introduced in version 0.25.

(30) Signature: Shape **insert** (const EdgePair edge_pair)

Description: Inserts an edge pair into the shapes list

This method has been introduced in version 0.26.

(31) Signature: Shape **insert** (const DEdgePair edge_pair)

Description: Inserts a micrometer-unit edge pair into the shapes list

Returns: A reference to the new shape (a Shape object)

This method behaves like the insert version with a EdgePair argument, except that it will internally translate the edge pair from micrometer to database units.

This variant has been introduced in version 0.26.

(32) Signature: Shape **insert** (const Point point)

Description: Inserts an point into the shapes list

This variant has been introduced in version 0.28.

(33) Signature: Shape **insert** (const DPoint point)

Description: Inserts a micrometer-unit point into the shapes list

Returns: A reference to the new shape (a Shape object)

This method behaves like the insert version with a Point argument, except that it will internally translate the point from micrometer to database units.

This variant has been introduced in version 0.28.

(34) Signature: Shape **insert** (const Text text)

Description: Inserts a text into the shapes list

Returns: A reference to the new shape (a Shape object)

Starting with version 0.16, this method returns a reference to the newly created shape

(35) Signature: Shape **insert** (const DText text)

Description: Inserts a micrometer-unit text into the shapes list

Returns: A reference to the new shape (a Shape object)

This method behaves like the insert version with a Text argument, except that it will internally translate the text from micrometer to database units.

This variant has been introduced in version 0.25.

(36) Signature: Shape **insert** (const SimplePolygon simple_polygon)

Description: Inserts a simple polygon into the shapes list

Returns: A reference to the new shape (a Shape object)

Starting with version 0.16, this method returns a reference to the newly created shape

(37) Signature: Shape **insert** (const DSimplePolygon simple_polygon)

Description: Inserts a micrometer-unit simple polygon into the shapes list

Returns: A reference to the new shape (a Shape object)

This method behaves like the insert version with a SimplePolygon argument, except that it will internally translate the polygon from micrometer to database units.

This variant has been introduced in version 0.25.

(38) Signature: Shape **insert** (const Polygon polygon)

Description: Inserts a polygon into the shapes list

Returns: A reference to the new shape (a Shape object)

Starting with version 0.16, this method returns a reference to the newly created shape

(39) Signature: Shape **insert** (const DPolygon polygon)

Description: Inserts a micrometer-unit polygon into the shapes list

Returns: A reference to the new shape (a Shape object)

This method behaves like the insert version with a Polygon argument, except that it will internally translate the polygon from micrometer to database units.

This variant has been introduced in version 0.25.

(40) Signature: Shape **insert** (const Box box, unsigned long property_id)

Description: Inserts a box with properties into the shapes list

Returns: A reference to the new shape (a Shape object)

The property Id must be obtained from the Layout object's property_id method which associates a property set with a property Id. Starting with version 0.16, this method returns a reference to the newly created shape

(41) Signature: Shape **insert** (const DBox box, unsigned long property_id)

Description: Inserts a micrometer-unit box with properties into the shapes list

Returns: A reference to the new shape (a Shape object)

This method behaves like the insert version with a Box argument and a property ID, except that it will internally translate the box from micrometer to database units.

This variant has been introduced in version 0.25.

(42) Signature: Shape **insert** (const Path path, unsigned long property_id)

Description: Inserts a path with properties into the shapes list

Returns: A reference to the new shape (a Shape object)

The property Id must be obtained from the Layout object's property_id method which associates a property set with a property Id. Starting with version 0.16, this method returns a reference to the newly created shape

(43) Signature: Shape **insert** (const DPath path, unsigned long property_id)

Description: Inserts a micrometer-unit path with properties into the shapes list

Returns: A reference to the new shape (a Shape object)

This method behaves like the insert version with a Path argument and a property ID, except that it will internally translate the path from micrometer to database units.

This variant has been introduced in version 0.25.

(44) Signature: Shape **insert** (const Edge edge, unsigned long property_id)

Description: Inserts an edge with properties into the shapes list

Returns: A reference to the new shape (a Shape object)

The property Id must be obtained from the Layout object's property_id method which associates a property set with a property Id. Starting with version 0.16, this method returns a reference to the newly created shape.

(45) Signature: Shape **insert** (const DEdge edge, unsigned long property_id)

Description: Inserts a micrometer-unit edge with properties into the shapes list

Returns: A reference to the new shape (a Shape object)

This method behaves like the insert version with a Edge argument and a property ID, except that it will internally translate the edge from micrometer to database units.

This variant has been introduced in version 0.25.

(46) Signature: Shape **insert** (const EdgePair edge_pair, unsigned long property_id)

Description: Inserts an edge pair with properties into the shapes list

Returns: A reference to the new shape (a Shape object)

The property Id must be obtained from the Layout object's property_id method which associates a property set with a property Id. This method has been introduced in version 0.26.

(47) Signature: Shape **insert** (const DEdgePair edge_pair, unsigned long property_id)

Description: Inserts a micrometer-unit edge pair with properties into the shapes list

Returns: A reference to the new shape (a Shape object)

This method behaves like the insert version with a EdgePair argument and a property ID, except that it will internally translate the edge pair from micrometer to database units.

This variant has been introduced in version 0.26.

(48) Signature: Shape **insert** (const Text text, unsigned long property_id)

Description: Inserts a text with properties into the shapes list

Returns: A reference to the new shape (a Shape object)

The property Id must be obtained from the Layout object's property_id method which associates a property set with a property Id. Starting with version 0.16, this method returns a reference to the newly created shape

(49) Signature: Shape **insert** (const DText text, unsigned long property_id)

Description: Inserts a micrometer-unit text with properties into the shapes list

Returns: A reference to the new shape (a Shape object)

This method behaves like the insert version with a Text argument and a property ID, except that it will internally translate the text from micrometer to database units.

This variant has been introduced in version 0.25.

(50) Signature: Shape **insert** (const SimplePolygon simple_polygon, unsigned long property_id)

Description: Inserts a simple polygon with properties into the shapes list

Returns: A reference to the new shape (a Shape object)

The property Id must be obtained from the Layout object's property_id method which associates a property set with a property Id. Starting with version 0.16, this method returns a reference to the newly created shape

(51) Signature: Shape **insert** (const DSimplePolygon simple_polygon, unsigned long property_id)

Description: Inserts a micrometer-unit simple polygon with properties into the shapes list

Returns: A reference to the new shape (a Shape object)

This method behaves like the insert version with a SimplePolygon argument and a property ID, except that it will internally translate the simple polygon from micrometer to database units.

This variant has been introduced in version 0.25.

(52) Signature: Shape **insert** (const Polygon polygon, unsigned long property_id)

Description: Inserts a polygon with properties into the shapes list

Returns: A reference to the new shape (a Shape object)

The property Id must be obtained from the Layout object's property_id method which associates a property set with a property Id. Starting with version 0.16, this method returns a reference to the newly created shape

(53) Signature: Shape **insert** (const DPolygon polygon, unsigned long property_id)

Description: Inserts a micrometer-unit polygon with properties into the shapes list

Returns: A reference to the new shape (a Shape object)

This method behaves like the insert version with a Polygon argument and a property ID, except that it will internally translate the polygon from micrometer to database units.

This variant has been introduced in version 0.25.

insert_as_edges

(1) Signature: void **insert_as_edges** (const EdgePairs edge_pairs)

Description: Inserts the edge pairs from the edge pair collection as individual edges into this shape container

edge_pairs: The edge pairs to insert

This method inserts all edge pairs from the edge pair collection into this shape container. Each edge from the edge pair is inserted individually into the shape container.

This method has been introduced in version 0.23.

(2) Signature: void **insert_as_edges** (const EdgePairs edge_pairs, const ICplxTrans trans)

Description: Inserts the edge pairs from the edge pair collection as individual into this shape container with a transformation

edges: The edge pairs to insert

trans: The transformation to apply

This method inserts all edge pairs from the edge pair collection into this shape container. Each edge from the edge pair is inserted individually into the shape container. Before each edge is inserted into the shape collection, the given transformation is applied.

This method has been introduced in version 0.23.

(3) Signature: void **insert_as_edges** (const EdgePairs edge_pairs, const DCplxTrans trans)

Description: Inserts the edge pairs from the edge pair collection as individual into this shape container with a transformation (given in micrometer units)

edges: The edge pairs to insert

trans: The transformation to apply (displacement in micrometer units)

This method inserts all edge pairs from the edge pair collection into this shape container. Each edge from the edge pair is inserted individually into the shape container. Before each edge is inserted into the shape collection, the given transformation is applied.

This method has been introduced in version 0.25.

insert_as_polygons

(1) Signature: void **insert_as_polygons** (const EdgePairs edge_pairs, int e)

Description: Inserts the edge pairs from the edge pair collection as polygons into this shape container

edge_pairs: The edge pairs to insert

e: The extension to apply when converting the edges to polygons (in database units)

This method inserts all edge pairs from the edge pair collection into this shape container. The edge pairs are converted to polygons covering the area between the edges. The extension parameter specifies a sizing which is applied when converting the edge pairs to polygons. This way, degenerated edge pairs (i.e. two point-like edges) do not vanish.

This method has been introduced in version 0.23.

(2) Signature: void **insert_as_polygons** (const EdgePairs edge_pairs, double e)

Description: Inserts the edge pairs from the edge pair collection as polygons into this shape container

edge_pairs: The edge pairs to insert

e: The extension to apply when converting the edges to polygons (in micrometer units)

This method is identical to the version with a integer-type e parameter, but for this version the e parameter is given in micrometer units.

This method has been introduced in version 0.25.

(3) Signature: void **insert_as_polygons** (const EdgePairs edge_pairs, const ICplxTrans e, int trans)

Description: Inserts the edge pairs from the edge pair collection as polygons into this shape container with a transformation

edges: The edge pairs to insert

e: The extension to apply when converting the edges to polygons (in database units)

trans: The transformation to apply

This method inserts all edge pairs from the edge pair collection into this shape container. The edge pairs are converted to polygons covering the area between the edges. The extension parameter specifies a sizing which is applied when converting the edge pairs to polygons. This way, degenerated edge pairs (i.e. two point-like edges) do not vanish. Before a polygon is inserted into the shape collection, the given transformation is applied.

This method has been introduced in version 0.23.

(4) Signature: void **insert_as_polygons** (const EdgePairs edge_pairs, const DCplxTrans e, double trans)

Description: Inserts the edge pairs from the edge pair collection as polygons into this shape container with a transformation

edges: The edge pairs to insert

e: The extension to apply when converting the edges to polygons (in micrometer units)

trans: The transformation to apply (displacement in micrometer units)

This method is identical to the version with a integer-type e and trans parameter, but for this version the e parameter is given in micrometer units and the trans parameter is a micrometer-unit transformation.

This method has been introduced in version 0.25.

insert_box

Signature: Shape **insert_box** (const Box box)

Description: Inserts a box into the shapes list

Returns: A reference to the new shape (a Shape object)

Use of this method is deprecated. Use insert instead

Starting with version 0.16, this method returns a reference to the newly created shape

insert_box_with_properties

Signature: Shape **insert_box_with_properties** (const Box box, unsigned long property_id)

Description: Inserts a box with properties into the shapes list

Returns: A reference to the new shape (a Shape object)

Use of this method is deprecated. Use insert instead

The property Id must be obtained from the Layout object's property_id method which associates a property set with a property Id. Starting with version 0.16, this method returns a reference to the newly created shape

insert_edge

Signature: Shape **insert_edge** (const Edge edge)

Description: Inserts an edge into the shapes list

Use of this method is deprecated. Use insert instead

Starting with version 0.16, this method returns a reference to the newly created shape

insert_edge_with_properties

Signature: Shape **insert_edge_with_properties** (const Edge edge, unsigned long property_id)

Description: Inserts an edge with properties into the shapes list

Returns: A reference to the new shape (a Shape object)

Use of this method is deprecated. Use insert instead

The property Id must be obtained from the Layout object's property_id method which associates a property set with a property Id. Starting with version 0.16, this method returns a reference to the newly created shape.

insert_path

Signature: Shape **insert_path** (const Path path)

Description: Inserts a path into the shapes list

Returns: A reference to the new shape (a Shape object)

Use of this method is deprecated. Use insert instead

Starting with version 0.16, this method returns a reference to the newly created shape

insert_path_with_properties

Signature: Shape **insert_path_with_properties** (const Path path, unsigned long property_id)

Description: Inserts a path with properties into the shapes list

Returns: A reference to the new shape (a Shape object)

Use of this method is deprecated. Use insert instead

The property Id must be obtained from the Layout object's property_id method which associates a property set with a property Id. Starting with version 0.16, this method returns a reference to the newly created shape

insert_point

Signature: Shape **insert_point** (const Point point)

Description: Inserts an point into the shapes list

Use of this method is deprecated. Use insert instead

This variant has been introduced in version 0.28.

insert_polygon

Signature: Shape **insert_polygon** (const Polygon polygon)

Description: Inserts a polygon into the shapes list

Returns: A reference to the new shape (a Shape object)

Use of this method is deprecated. Use insert instead

Starting with version 0.16, this method returns a reference to the newly created shape

insert_polygon_with_properties

Signature: Shape **insert_polygon_with_properties** (const Polygon polygon, unsigned long property_id)

Description: Inserts a polygon with properties into the shapes list

Returns: A reference to the new shape (a Shape object)

Use of this method is deprecated. Use insert instead

The property Id must be obtained from the Layout object's property_id method which associates a property set with a property Id. Starting with version 0.16, this method returns a reference to the newly created shape

insert_simple_polygon

Signature: Shape **insert_simple_polygon** (const SimplePolygon simple_polygon)

Description: Inserts a simple polygon into the shapes list

Returns: A reference to the new shape (a Shape object)

Use of this method is deprecated. Use insert instead

Starting with version 0.16, this method returns a reference to the newly created shape

insert_simple_polygon_with_properties

Signature: Shape **insert_simple_polygon_with_properties** (const SimplePolygon simple_polygon, unsigned long property_id)

Description: Inserts a simple polygon with properties into the shapes list

Returns: A reference to the new shape (a Shape object)

Use of this method is deprecated. Use insert instead

The property Id must be obtained from the Layout object's property_id method which associates a property set with a property Id. Starting with version 0.16, this method returns a reference to the newly created shape

insert_text

Signature: Shape **insert_text** (const Text text)

Description: Inserts a text into the shapes list

Returns: A reference to the new shape (a Shape object)

Use of this method is deprecated. Use insert instead

Starting with version 0.16, this method returns a reference to the newly created shape

insert_text_with_properties

Signature: Shape **insert_text_with_properties** (const Text text, unsigned long property_id)

Description: Inserts a text with properties into the shapes list

Returns: A reference to the new shape (a Shape object)

Use of this method is deprecated. Use insert instead

The property Id must be obtained from the Layout object's property_id method which associates a property set with a property Id. Starting with version 0.16, this method returns a reference to the newly created shape

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_empty?

Signature: *[const]* bool **is_empty?**

Description: Returns a value indicating whether the shapes container is empty

This method has been introduced in version 0.20.

is_valid?

Signature: *[const]* bool **is_valid?** (const Shape shape)

Description: Tests if the given Shape object is still pointing to a valid object

This method has been introduced in version 0.16. If the shape represented by the given reference has been deleted, this method returns false. If however, another shape has been inserted already that occupies the original shape's position, this method will return true again.

layout

Signature: Layout ptr **layout**

Description: Gets the layout object the shape container belongs to

This method returns nil if the shape container does not belong to a layout.

This method has been added in version 0.28.

new

Signature: *[static]* new Shapes ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

replace

(1) Signature: Shape **replace** (const Shape shape, const Box box)

Description: Replaces the given shape with a box

Returns: A reference to the new shape (a Shape object)

This method has been introduced with version 0.16. It replaces the given shape with the object specified. It does not change the property Id. To change the property Id, use the replace_prop_id method. To replace a shape and discard the property Id, erase the shape and insert a new shape. This method is permitted in editable mode only.

(2) Signature: Shape **replace** (const Shape shape, const DBox box)

Description: Replaces the given shape with a box given in micrometer units

Returns: A reference to the new shape (a Shape object)

This method behaves like the replace version with a Box argument, except that it will internally translate the box from micrometer to database units.

This variant has been introduced in version 0.25.

(3) Signature: Shape **replace** (const Shape shape, const Path path)

Description: Replaces the given shape with a path

Returns: A reference to the new shape (a Shape object)

This method has been introduced with version 0.16. It replaces the given shape with the object specified. It does not change the property Id. To change the property Id, use the replace_prop_id method. To replace a shape and discard the property Id, erase the shape and insert a new shape. This method is permitted in editable mode only.

(4) Signature: Shape **replace** (const Shape shape, const DPath path)

Description: Replaces the given shape with a path given in micrometer units

Returns: A reference to the new shape (a Shape object)

This method behaves like the replace version with a Path argument, except that it will internally translate the path from micrometer to database units.

This variant has been introduced in version 0.25.

(5) Signature: Shape **replace** (const Shape shape, const Edge edge)

Description: Replaces the given shape with an edge object

This method has been introduced with version 0.16. It replaces the given shape with the object specified. It does not change the property Id. To change the property Id, use the replace_prop_id method. To replace a shape and discard the property Id, erase the shape and insert a new shape. This method is permitted in editable mode only.

(6) Signature: Shape **replace** (const Shape shape, const DEdge edge)

Description: Replaces the given shape with an edge given in micrometer units

Returns: A reference to the new shape (a Shape object)

This method behaves like the replace version with an Edge argument, except that it will internally translate the edge from micrometer to database units.

This variant has been introduced in version 0.25.

(7) Signature: Shape **replace** (const Shape shape, const EdgePair edge_pair)

Description: Replaces the given shape with an edge pair object

It replaces the given shape with the object specified. It does not change the property Id. To change the property Id, use the replace_prop_id method. To replace a shape and discard the property Id, erase the shape and insert a new shape. This method is permitted in editable mode only.

This method has been introduced in version 0.26.

(8) Signature: Shape **replace** (const Shape shape, const DEdgePair edge_pair)

Description: Replaces the given shape with an edge pair given in micrometer units

Returns: A reference to the new shape (a Shape object)

This method behaves like the replace version with an EdgePair argument, except that it will internally translate the edge pair from micrometer to database units.

This variant has been introduced in version 0.26.

(9) Signature: Shape **replace** (const Shape shape, const Point point)

Description: Replaces the given shape with an point object

This method replaces the given shape with the object specified. It does not change the property Id. To change the property Id, use the replace_prop_id method. To replace a shape and discard the

property Id, erase the shape and insert a new shape. This variant has been introduced in version 0.28.

(10) Signature: Shape **replace** (const Shape shape, const DPoint point)

Description: Replaces the given shape with an point given in micrometer units

Returns: A reference to the new shape (a Shape object)

This method behaves like the replace version with an Point argument, except that it will internally translate the point from micrometer to database units.

This variant has been introduced in version 0.28.

(11) Signature: Shape **replace** (const Shape shape, const Text text)

Description: Replaces the given shape with a text object

Returns: A reference to the new shape (a Shape object)

This method has been introduced with version 0.16. It replaces the given shape with the object specified. It does not change the property Id. To change the property Id, use the replace_prop_id method. To replace a shape and discard the property Id, erase the shape and insert a new shape. This method is permitted in editable mode only.

(12) Signature: Shape **replace** (const Shape shape, const DText text)

Description: Replaces the given shape with a text given in micrometer units

Returns: A reference to the new shape (a Shape object)

This method behaves like the replace version with a Text argument, except that it will internally translate the text from micrometer to database units.

This variant has been introduced in version 0.25.

(13) Signature: Shape **replace** (const Shape shape, const SimplePolygon simple_polygon)

Description: Replaces the given shape with a simple polygon

Returns: A reference to the new shape (a Shape object)

This method has been introduced with version 0.16. It replaces the given shape with the object specified. It does not change the property Id. To change the property Id, use the replace_prop_id method. To replace a shape and discard the property Id, erase the shape and insert a new shape. This method is permitted in editable mode only.

(14) Signature: Shape **replace** (const Shape shape, const DSimplePolygon simple_polygon)

Description: Replaces the given shape with a simple polygon given in micrometer units

Returns: A reference to the new shape (a Shape object)

This method behaves like the replace version with a SimplePolygon argument, except that it will internally translate the simple polygon from micrometer to database units.

This variant has been introduced in version 0.25.

(15) Signature: Shape **replace** (const Shape shape, const Polygon polygon)

Description: Replaces the given shape with a polygon

Returns: A reference to the new shape (a Shape object)

This method has been introduced with version 0.16. It replaces the given shape with the object specified. It does not change the property Id. To change the property Id, use the replace_prop_id

method. To replace a shape and discard the property Id, erase the shape and insert a new shape. This method is permitted in editable mode only.

(16) Signature: Shape **replace** (const Shape shape, const DPolygon polygon)

Description: Replaces the given shape with a polygon given in micrometer units

Returns: A reference to the new shape (a Shape object)

This method behaves like the replace version with a Polygon argument, except that it will internally translate the polygon from micrometer to database units.

This variant has been introduced in version 0.25.

replace_prop_id

Signature: Shape **replace_prop_id** (const Shape shape, unsigned long property_id)

Description: Replaces (or install) the properties of a shape

Returns: A Shape object representing the new shape

This method has been introduced in version 0.16. It can only be used in editable mode. Changes the properties Id of the given shape or install a properties Id on that shape if it does not have one yet. The property Id must be obtained from the Layout object's property_id method which associates a property set with a property Id. This method will potentially invalidate the shape reference passed to it. Use the reference returned for future references.

s_all

Signature: *[static]* unsigned int **s_all**

Description: Indicates that all shapes shall be retrieved

Use of this method is deprecated. Use SAll instead

You can use this constant to construct 'except' classes - e.g. to specify 'all shape types except boxes' use

```
SAll - SBoxes
```

Python specific notes:
The object exposes a readable attribute 'SAll'. This is the getter.

s_all_with_properties

Signature: *[static]* unsigned int **s_all_with_properties**

Description: Indicates that all shapes with properties shall be retrieved

Use of this method is deprecated. Use SAllWithProperties instead

Using this selector means to retrieve only shapes with properties.You can use this constant to construct 'except' classes - e.g. to specify 'all shape types with properties except boxes' use

```
SAllWithProperties - SBoxes
```

Python specific notes:
The object exposes a readable attribute 'SAllWithProperties'. This is the getter.

s_boxes

Signature: *[static]* unsigned int **s_boxes**

Description: Indicates that boxes shall be retrieved

Use of this method is deprecated. Use SBoxes instead

Python specific notes:
The object exposes a readable attribute 'SBoxes'. This is the getter.

s_edge_pairs

Signature: *[static]* unsigned int **s_edge_pairs**

Description: Indicates that edge pairs shall be retrieved

Use of this method is deprecated. Use SEdgePairs instead

Python specific notes:
The object exposes a readable attribute 'SEdgePairs'. This is the getter.

s_edges

Signature: *[static]* unsigned int **s_edges**

Description: Indicates that edges shall be retrieved

Use of this method is deprecated. Use SEdges instead

Python specific notes:
The object exposes a readable attribute 'SEdges'. This is the getter.

s_paths

Signature: *[static]* unsigned int **s_paths**

Description: Indicates that paths shall be retrieved

Use of this method is deprecated. Use SPaths instead

Python specific notes:
The object exposes a readable attribute 'SPaths'. This is the getter.

s_points

Signature: *[static]* unsigned int **s_points**

Description: Indicates that points shall be retrieved

Use of this method is deprecated. Use SPoints instead

This constant has been added in version 0.28.

Python specific notes:
The object exposes a readable attribute 'SPoints'. This is the getter.

s_polygons

Signature: *[static]* unsigned int **s_polygons**

Description: Indicates that polygons shall be retrieved

Use of this method is deprecated. Use SPolygons instead

Python specific notes:
The object exposes a readable attribute 'SPolygons'. This is the getter.

s_properties

Signature: *[static]* unsigned int **s_properties**

Description: Indicates that only shapes with properties shall be retrieved

Use of this method is deprecated. Use SProperties instead

You can or-combine this flag with the plain shape types to select a certain shape type, but only those shapes with properties. For example to select boxes with properties, use 'SProperties | SBoxes'.

Python specific notes:
The object exposes a readable attribute 'SProperties'. This is the getter.

s_regions

Signature: *[static]* unsigned int **s_regions**

Description: Indicates that objects which can be polygonized shall be retrieved (paths, boxes, polygons etc.)

Use of this method is deprecated. Use SRegions instead

This constant has been added in version 0.27.

Python specific notes:

The object exposes a readable attribute 'SRegions'. This is the getter.

s_texts

Signature: *[static]* unsigned int **s_texts**

Description: Indicates that texts be retrieved

Use of this method is deprecated. Use STexts instead

Python specific notes:
The object exposes a readable attribute 'STexts'. This is the getter.

s_user_objects

Signature: *[static]* unsigned int **s_user_objects**

Description: Indicates that user objects shall be retrieved

Use of this method is deprecated. Use SUserObjects instead

Python specific notes:
The object exposes a readable attribute 'SUserObjects'. This is the getter.

size

Signature: *[const]* unsigned long **size**

Description: Gets the number of shapes in this container

Returns: The number of shapes in this container

This method was introduced in version 0.16

Python specific notes:
This method is also available as 'len(object)'.

transform

(1) Signature: void **transform** (const Trans trans)

Description: Transforms all shapes with the given transformation

This method will invalidate all references to shapes inside this collection.

It has been introduced in version 0.23.

(2) Signature: void **transform** (const DTrans trans)

Description: Transforms all shapes with the given transformation (given in micrometer units)

This method will invalidate all references to shapes inside this collection. The displacement of the transformation is given in micrometer units.

It has been introduced in version 0.25.

(3) Signature: void **transform** (const ICplxTrans trans)

Description: Transforms all shapes with the given complex integer transformation

This method will invalidate all references to shapes inside this collection.

It has been introduced in version 0.23.

(4) Signature: void **transform** (const DCplxTrans trans)

Description: Transforms all shapes with the given transformation (given in micrometer units)

This method will invalidate all references to shapes inside this collection. The displacement of the transformation is given in micrometer units.

It has been introduced in version 0.25.

(5) Signature: Shape **transform** (const Shape shape, const Trans trans)

Description: Transforms the shape given by the reference with the given transformation

Returns: A reference (a Shape object) to the new shape

The original shape may be deleted and re-inserted by this method. Therefore, a new reference is returned. It is permitted in editable mode only.

This method has been introduced in version 0.16.

(6) Signature: Shape **transform** (const Shape shape, const DTrans trans)

Description: Transforms the shape given by the reference with the given transformation, where the transformation is given in micrometer units

trans: The transformation to apply (displacement in micrometer units)

Returns: A reference (a Shape object) to the new shape

The original shape may be deleted and re-inserted by this method. Therefore, a new reference is returned. It is permitted in editable mode only. This method has been introduced in version 0.25.

(7) Signature: Shape **transform** (const Shape shape, const ICplxTrans trans)

Description: Transforms the shape given by the reference with the given complex integer space transformation

Returns: A reference (a Shape object) to the new shape

This method has been introduced in version 0.22. The original shape may be deleted and re-inserted by this method. Therefore, a new reference is returned. It is permitted in editable mode only.

(8) Signature: Shape **transform** (const Shape shape, const DCplxTrans trans)

Description: Transforms the shape given by the reference with the given complex transformation, where the transformation is given in micrometer units

trans: The transformation to apply (displacement in micrometer units)

Returns: A reference (a Shape object) to the new shape

The original shape may be deleted and re-inserted by this method. Therefore, a new reference is returned. It is permitted in editable mode only. This method has been introduced in version 0.25.

4.97. API reference - Class TechnologyComponent

Notation used in Ruby API documentation

Module: db

Description: A part of a technology definition

Technology components extend technology definitions (class Technology) by specialized subfeature definitions. For example, the net tracer supplies its technology-dependent specification through a technology component called NetTracerTechnology.

Components are managed within technologies and can be accessed from a technology using Technology#component.

This class has been introduced in version 0.25.

Public constructors

new TechnologyComponent ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference
	void	**_manage**	Marks the object as managed by the script side.
	void	**_unmanage**	Marks the object as no longer owned by the script side.
[const]	string	**description**	Gets the human-readable description string of the technology component
[const]	string	**name**	Gets the formal name of the technology component

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

description

Signature: *[const]* string **description**

Description: Gets the human-readable description string of the technology component

destroy	**Signature**: void **destroy** **Description**: Explicitly destroys the object Use of this method is deprecated. Use _destroy instead Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
destroyed?	**Signature**: *[const]* bool **destroyed?** **Description**: Returns a value indicating whether the object was already destroyed Use of this method is deprecated. Use _destroyed? instead This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
is_const_object?	**Signature**: *[const]* bool **is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.
name	**Signature**: *[const]* string **name** **Description**: Gets the formal name of the technology component This is the name by which the component can be obtained from a technology using Technology#component.
new	**Signature**: *[static]* new TechnologyComponent ptr **new** **Description**: Creates a new object of this class **Python specific notes:** This method is the default initializer of the object.

4.98. API reference - Class Technology

Notation used in Ruby API documentation

Module: db

Description: Represents a technology

This class represents one technology from a set of technologies. The set of technologies available in the system can be obtained with technology_names. Individual technology definitions are returned with technology_by_name. Use create_technology to register new technologies and remove_technology to delete technologies.

Note that a Technology object needs to be registered in the system, before its name can be used to specify a technology, for example in Layout#technology_name. Technology objects created by create_technology are automatically registered. If you create a Technology object directly, you need to register it explicitly:

```
tech = RBA::Technology::new
tech.load("mytech.lyt")
RBA::Technology::register_technology(tech)
```

Note that in the latter example, an exception will be thrown if a technology with the same name already exists. Also note, that Technology#register will register a copy of the object, so modifying it after registration will not have any effect.

The Technology class has been introduced in version 0.25.

Public constructors

new Technology ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**add_other_layers=**	(bool add)	Sets the flag indicating whether to add other layers to the layer properties
[const]	bool	**add_other_layers?**		Gets the flag indicating whether to add other layers to the layer properties
	void	**assign**	(const Technology other)	Assigns another object to self
[const]	string	**base_path**		Gets the base path of the technology

	TechnologyComponent ptr	**component**	(string name)	Gets the technology component with the given name
[const]	string[]	**component_names**		Gets the names of all components available for component
[const]	string	**correct_path**	(string path)	Makes a file path relative to the base path if one is specified
[const]	double	**dbu**		Gets the default database unit
	void	**dbu=**	(double dbu)	Sets the default database unit
[const]	string	**default_base_path**		Gets the default base path
[const]	double	**default_grid**		Gets the default grid
[const]	double[]	**default_grids**		Gets the default grids
	void	**default_grids=**	(double[] grids)	Sets the default grids
[const]	string	**description**		Gets the description
	void	**description=**	(string description)	Sets the description
[const]	new Technology ptr	**dup**		Creates a copy of self
[const]	string	**eff_layer_properties_file**		Gets the effective path of the layer properties file
[const]	string	**eff_path**	(string path)	Makes a file path relative to the base path if one is specified
[const]	string	**explicit_base_path**		Gets the explicit base path
	void	**explicit_base_path=**	(string path)	Sets the explicit base path
[const]	string	**group**		Gets the technology group
	void	**group=**	(string group)	Sets the technology group
[const]	string	**layer_properties_file**		Gets the path of the layer properties file
	void	**layer_properties_file=**	(string file)	Sets the path of the layer properties file
	void	**load**	(string file)	Loads the technology definition from a file
[const]	LoadLayoutOptions	**load_layout_options**		Gets the layout reader options
	void	**load_layout_options=**	(const LoadLayoutOptio options)	Sets the layout reader options
[const]	string	**name**		Gets the name of the technology
	void	**name=**	(string name)	Sets the name of the technology

[const]	void	**save**	(string file)	Saves the technology definition to a file
[const]	SaveLayoutOptions	**save_layout_options**		Gets the layout writer options
	void	**save_layout_options=**	(const SaveLayoutOptions options)	Sets the layout writer options
	void	**set_default_grids**	(double[] grids, double default_grid = 0)	Sets the default grids and the strong default one
[const]	string	**to_xml**		Returns a XML representation of this technolog

Public static methods and constants

void	**clear_technologies**		Clears all technologies
Technology ptr	**create_technology**	(string name)	Creates a new (empty) technology with the given name
bool	**has_technology?**	(string name)	Returns a value indicating whether there is a technology with this name
Technology ptr	**register_technology**	(const Technology tech)	Registers a technology in the system
void	**remove_technology**	(string name)	Removes the technology with the given name from the system
void	**technologies_from_xml**	(string xml)	Loads the technologies from a XML representation
string	**technologies_to_xml**		Returns a XML representation of all technologies registered in the system
Technology ptr	**technology_by_name**	(string name)	Gets the technology object for a given name
Technology	**technology_from_xml**	(string xml)	Loads the technology from a XML representation
string[]	**technology_names**		Gets a list of technology names defined in the system

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead

[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

add_other_layers=

Signature: void **add_other_layers=** (bool add)

Description: Sets the flag indicating whether to add other layers to the layer properties

Python specific notes:

	The object exposes a writable attribute 'add_other_layers'. This is the setter.
add_other_layers?	**Signature**: *[const]* bool **add_other_layers?** **Description**: Gets the flag indicating whether to add other layers to the layer properties **Python specific notes:** The object exposes a readable attribute 'add_other_layers'. This is the getter.
assign	**Signature**: void **assign** (const Technology other) **Description**: Assigns another object to self
base_path	**Signature**: *[const]* string **base_path** **Description**: Gets the base path of the technology The base path is the effective path where files are read from if their file path is a relative one. If the explicit path is set (see explicit_base_path=), it is used. If not, the default path is used. The default path is the one from which a technology file was imported. The explicit one is the one that is specified explicitly with explicit_base_path=.
clear_technologies	**Signature**: *[static]* void **clear_technologies** **Description**: Clears all technologies This method has been introduced in version 0.26.
component	**Signature**: TechnologyComponent ptr **component** (string name) **Description**: Gets the technology component with the given name The names are unique system identifiers. For all names, use component_names.
component_names	**Signature**: *[const]* string[] **component_names** **Description**: Gets the names of all components available for component
correct_path	**Signature**: *[const]* string **correct_path** (string path) **Description**: Makes a file path relative to the base path if one is specified This method turns an absolute path into one relative to the base path. Only files below the base path will be made relative. Files above or beside won't be made relative. See base_path for details about the default base path.
create	**Signature**: void **create** **Description**: Ensures the C++ object is created Use of this method is deprecated. Use _create instead Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
create_technology	**Signature**: *[static]* Technology ptr **create_technology** (string name) **Description**: Creates a new (empty) technology with the given name The new technology is already registered in the system.

This method returns a reference to the new technology.

dbu

Signature: *[const]* double **dbu**

Description: Gets the default database unit

The default database unit is the one used when creating a layout for example.

Python specific notes:
The object exposes a readable attribute 'dbu'. This is the getter.

dbu=

Signature: void **dbu=** (double dbu)

Description: Sets the default database unit

Python specific notes:
The object exposes a writable attribute 'dbu'. This is the setter.

default_base_path

Signature: *[const]* string **default_base_path**

Description: Gets the default base path

See base_path for details about the default base path.

Python specific notes:
The object exposes a readable attribute 'default_base_path'. This is the getter.

default_grid

Signature: *[const]* double **default_grid**

Description: Gets the default grid

The default grid is a specific one from the default grid list. It indicates the one that is taken if the current grid is not matching one of the default grids.

To set the default grid, use set_default_grids.

This property has been introduced in version 0.29.

default_grids

Signature: *[const]* double[] **default_grids**

Description: Gets the default grids

See default_grids for details.

This property has been introduced in version 0.28.17.

Python specific notes:
The object exposes a readable attribute 'default_grids'. This is the getter.

default_grids=

Signature: void **default_grids=** (double[] grids)

Description: Sets the default grids

If not empty, this list replaces the global grid list for this technology. Note that this method will reset the default grid (see default_grid). Use set_default_grids to set the default grids and the strong default one.

This property has been introduced in version 0.28.17.

Python specific notes:
The object exposes a writable attribute 'default_grids'. This is the setter.

description

Signature: *[const]* string **description**

Description: Gets the description

The technology description is shown to the user in technology selection dialogs and for display purposes.

Python specific notes:
The object exposes a readable attribute 'description'. This is the getter.

description=

Signature: void **description=** (string description)

Description: Sets the description

Python specific notes:
The object exposes a writable attribute 'description'. This is the setter.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new Technology ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

eff_layer_properties_file

Signature: *[const]* string **eff_layer_properties_file**

Description: Gets the effective path of the layer properties file

eff_path

Signature: *[const]* string **eff_path** (string path)

Description: Makes a file path relative to the base path if one is specified

This method will return the actual path for a file from the file's path. If the input path is a relative one, it will be made absolute by using the base path.

See base_path for details about the default base path.

explicit_base_path

Signature: *[const]* string **explicit_base_path**

Description: Gets the explicit base path

See base_path for details about the explicit base path.

Python specific notes:
The object exposes a readable attribute 'explicit_base_path'. This is the getter.

explicit_base_path=

Signature: void **explicit_base_path=** (string path)

Description: Sets the explicit base path

See base_path for details about the explicit base path.

Python specific notes:
The object exposes a writable attribute 'explicit_base_path'. This is the setter.

group

Signature: *[const]* string **group**

Description: Gets the technology group

The technology group is used to group certain technologies together in the technology selection menu. Technologies with the same group are put under a submenu with that group title.

The 'group' attribute has been introduced in version 0.26.2.

Python specific notes:
The object exposes a readable attribute 'group'. This is the getter.

group=

Signature: void **group=** (string group)

Description: Sets the technology group

See group for details about this attribute.

The 'group' attribute has been introduced in version 0.26.2.

Python specific notes:
The object exposes a writable attribute 'group'. This is the setter.

has_technology?

Signature: *[static]* bool **has_technology?** (string name)

Description: Returns a value indicating whether there is a technology with this name

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

layer_properties_file

Signature: *[const]* string **layer_properties_file**

Description: Gets the path of the layer properties file

If empty, no layer properties file is associated with the technology. If non-empty, this path will be corrected by the base path (see correct_path) and this layer properties file will be loaded for layouts with this technology.

Python specific notes:
The object exposes a readable attribute 'layer_properties_file'. This is the getter.

layer_properties_file=

Signature: void **layer_properties_file=** (string file)

Description: Sets the path of the layer properties file

See layer_properties_file for details about this property.

Python specific notes:
The object exposes a writable attribute 'layer_properties_file'. This is the setter.

load

Signature: void **load** (string file)

Description: Loads the technology definition from a file

load_layout_options

Signature: *[const]* LoadLayoutOptions **load_layout_options**

Description: Gets the layout reader options

This method returns the layout reader options that are used when reading layouts with this technology.

Change the reader options by modifying the object and using the setter to change it:

```
opt = tech.load_layout_options
opt.dxf_dbu = 2.5
tech.load_layout_options = opt
```

Python specific notes:
The object exposes a readable attribute 'load_layout_options'. This is the getter.

load_layout_options=

Signature: void **load_layout_options=** (const LoadLayoutOptions options)

Description: Sets the layout reader options

See load_layout_options for a description of this property.

Python specific notes:
The object exposes a writable attribute 'load_layout_options'. This is the setter.

name

Signature: *[const]* string **name**

Description: Gets the name of the technology

Python specific notes:
The object exposes a readable attribute 'name'. This is the getter.

name=

Signature: void **name=** (string name)

Description: Sets the name of the technology

Python specific notes:
The object exposes a writable attribute 'name'. This is the setter.

new

Signature: *[static]* new Technology ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

register_technology

Signature: *[static]* Technology ptr **register_technology** (const Technology tech)

Description: Registers a technology in the system

Only after a technology is registered, it can be used in the system, e.g. by specifying its name in Layout#technology_name. While create_technology already registers the technology, this method allows registering a Technology object that has created in other ways.

This method returns a reference to the new technology object, which is a copy of the argument. remove_technology can be used to remove a technology registered by this method.

This method has been introduced in version 0.28.14.

remove_technology

Signature: *[static]* void **remove_technology** (string name)

Description: Removes the technology with the given name from the system

save

Signature: *[const]* void **save** (string file)

Description: Saves the technology definition to a file

save_layout_options

Signature: *[const]* SaveLayoutOptions **save_layout_options**

Description: Gets the layout writer options

This method returns the layout writer options that are used when writing layouts with this technology.

Change the reader options by modifying the object and using the setter to change it:

```
opt = tech.save_layout_options
opt.dbu = 0.01
tech.save_layout_options = opt
```

Python specific notes:
The object exposes a readable attribute 'save_layout_options'. This is the getter.

save_layout_options=

Signature: void **save_layout_options=** (const SaveLayoutOptions options)

Description: Sets the layout writer options

See save_layout_options for a description of this property.

Python specific notes:
The object exposes a writable attribute 'save_layout_options'. This is the setter.

set_default_grids

Signature: void **set_default_grids** (double[] grids, double default_grid = 0)

Description: Sets the default grids and the strong default one

See default_grids and default_grid for a description of this property. Note that the default grid has to be a member of the 'grids' array to become active.

This method has been introduced in version 0.29.

technologies_from_xml

Signature: *[static]* void **technologies_from_xml** (string xml)

Description: Loads the technologies from a XML representation

See technologies_to_xml for details.

technologies_to_xml

Signature: *[static]* string **technologies_to_xml**

Description: Returns a XML representation of all technologies registered in the system

technologies_from_xml can be used to restore the technology definitions. This method is provided mainly as a substitute for the pre-0.25 way of accessing technology data through the 'technology-data' configuration parameter. This method will return the equivalent string.

technology_by_name

Signature: *[static]* Technology ptr **technology_by_name** (string name)

Description: Gets the technology object for a given name

technology_from_xml

Signature: *[static]* Technology **technology_from_xml** (string xml)

Description: Loads the technology from a XML representation

	See technology_to_xml for details. Note that this function will create a new Technology object which is not registered in the system. See Technology#register for details.
technology_names	**Signature**: *[static]* string[] **technology_names** **Description**: Gets a list of technology names defined in the system
to_xml	**Signature**: *[const]* string **to_xml** **Description**: Returns a XML representation of this technolog technology_from_xml can be used to restore the technology definition.

4.99. API reference - Class Text

Notation used in Ruby API documentation

Module: db

Description: A text object

A text object has a point (location), a text, a text transformation, a text size and a font id. Text size and font id are provided to be be able to render the text correctly. Text objects are used as labels (i.e. for pins) or to indicate a particular position.

The Text class uses integer coordinates. A class that operates with floating-point coordinates is DText.

See The Database API for more details about the database objects.

Public constructors

new Text ptr	**new**	(const DText dtext)	Creates an integer coordinate text from a floating-point coordinate text
new Text ptr	**new**		Default constructor
new Text ptr	**new**	(string string, const Trans trans)	Constructor with string and transformation
new Text ptr	**new**	(string string, int x, int y)	Constructor with string and location
new Text ptr	**new**	(string string, const Trans trans, int height, int font)	Constructor with string, transformation, text height and font

Public methods

[const]	bool	**!=**	(const Text text)	Inequality
[const]	bool	**<**	(const Text t)	Less operator
[const]	bool	**==**	(const Text text)	Equality
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.

	void	**assign**	(const Text other)	Assigns another object to self
[const]	Box	**bbox**		Gets the bounding box of the text
[const]	new Text ptr	**dup**		Creates a copy of self
[const]	int	**font**		Gets the font number
	void	**font=**	(int f)	Sets the font number
[const]	HAlign	**halign**		Gets the horizontal alignment
	void	**halign=**	(HAlign a)	Sets the horizontal alignment
[const]	unsigned long	**hash**		Computes a hash value
	Text	**move**	(const Vector distance)	Moves the text by a certain distance (modifies self)
	Text	**move**	(int dx, int dy)	Moves the text by a certain distance (modifies self)
[const]	Text	**moved**	(const Vector distance)	Returns the text moved by a certain distance (does not modify self)
[const]	Text	**moved**	(int dx, int dy)	Returns the text moved by a certain distance (does not modify self)
[const]	Point	**position**		Gets the position of the text
[const]	int	**size**		Gets the text height
	void	**size=**	(int s)	Sets the text height of this object
[const]	string	**string**		Get the text string
	void	**string=**	(string text)	Assign a text string to this object
[const]	DText	**to_dtype**	(double dbu = 1)	Converts the text to a floating-point coordinate text
[const]	string	**to_s**	(double dbu = 0)	Converts the object to a string.
[const]	Trans	**trans**		Gets the transformation
	void	**trans=**	(const Trans t)	Assign a transformation (text position and orientation) to this object
[const]	Text	**transformed**	(const ICplxTrans t)	Transform the text with the given complex transformation
[const]	Text	**transformed**	(const Trans t)	Transforms the text with the given simple transformation
[const]	DText	**transformed**	(const CplxTrans t)	Transforms the text with the given complex transformation

[const]	VAlign	**valign**		Gets the vertical alignment
	void	**valign=**	(VAlign a)	Sets the vertical alignment
[const]	int	**x**		Gets the x location of the text
	void	**x=**	(int x)	Sets the x location of the text
[const]	int	**y**		Gets the y location of the text
	void	**y=**	(int y)	Sets the y location of the text

Public static methods and constants

[static,const]	HAlign	**HAlignCenter**		Centered horizontal alignment
[static,const]	HAlign	**HAlignLeft**		Left horizontal alignment
[static,const]	HAlign	**HAlignRight**		Right horizontal alignment
[static,const]	HAlign	**NoHAlign**		Undefined horizontal alignment
[static,const]	VAlign	**NoVAlign**		Undefined vertical alignment
[static,const]	VAlign	**VAlignBottom**		Bottom vertical alignment
[static,const]	VAlign	**VAlignCenter**		Centered vertical alignment
[static,const]	VAlign	**VAlignTop**		Top vertical alignment
	new Text ptr	**from_s**	(string s)	Creates an object from a string

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**		Use of this method is deprecated. Use _create instead
	void	**destroy**		Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**		Use of this method is deprecated. Use _destroyed? instead
	void	**halign=**	(int a)	Use of this method is deprecated
[const]	bool	**is_const_object?**		Use of this method is deprecated. Use _is_const_object? instead
	void	**valign=**	(int a)	Use of this method is deprecated

Detailed description

!=

Signature: *[const]* bool **!=** (const Text text)
Description: Inequality

	Return true, if this text object and the given text are not equal
<	**Signature**: *[const]* bool **<** (const Text t) **Description**: Less operator **t**: The object to compare against This operator is provided to establish some, not necessarily a certain sorting order
==	**Signature**: *[const]* bool **==** (const Text text) **Description**: Equality Return true, if this text object and the given text are equal
HAlignCenter	**Signature**: *[static,const]* HAlign **HAlignCenter** **Description**: Centered horizontal alignment **Python specific notes:** The object exposes a readable attribute 'HAlignCenter'. This is the getter.
HAlignLeft	**Signature**: *[static,const]* HAlign **HAlignLeft** **Description**: Left horizontal alignment **Python specific notes:** The object exposes a readable attribute 'HAlignLeft'. This is the getter.
HAlignRight	**Signature**: *[static,const]* HAlign **HAlignRight** **Description**: Right horizontal alignment **Python specific notes:** The object exposes a readable attribute 'HAlignRight'. This is the getter.
NoHAlign	**Signature**: *[static,const]* HAlign **NoHAlign** **Description**: Undefined horizontal alignment **Python specific notes:** The object exposes a readable attribute 'NoHAlign'. This is the getter.
NoVAlign	**Signature**: *[static,const]* VAlign **NoVAlign** **Description**: Undefined vertical alignment **Python specific notes:** The object exposes a readable attribute 'NoVAlign'. This is the getter.
VAlignBottom	**Signature**: *[static,const]* VAlign **VAlignBottom** **Description**: Bottom vertical alignment **Python specific notes:** The object exposes a readable attribute 'VAlignBottom'. This is the getter.
VAlignCenter	**Signature**: *[static,const]* VAlign **VAlignCenter** **Description**: Centered vertical alignment **Python specific notes:** The object exposes a readable attribute 'VAlignCenter'. This is the getter.

VAlignTop

Signature: *[static,const]* VAlign **VAlignTop**

Description: Top vertical alignment

Python specific notes:
The object exposes a readable attribute 'VAlignTop'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const Text other)

Description: Assigns another object to self

bbox

Signature: *[const]* Box **bbox**

Description: Gets the bounding box of the text

The bounding box of the text is a single point - the location of the text. Both points of the box are identical.

This method has been added in version 0.28.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new Text ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

font

Signature: *[const]* int **font**

Description: Gets the font number

See font= for a description of this property.

Python specific notes:
The object exposes a readable attribute 'font'. This is the getter.

font=

Signature: void **font=** (int f)

Description: Sets the font number

The font number does not play a role for KLayout. This property is provided for compatibility with other systems which allow using different fonts for the text objects.

Python specific notes:
The object exposes a writable attribute 'font'. This is the setter.

from_s

Signature: *[static]* new Text ptr **from_s** (string s)

Description: Creates an object from a string

Creates the object from a string representation (as returned by to_s)

This method has been added in version 0.23.

halign

Signature: *[const]* HAlign **halign**

Description: Gets the horizontal alignment

See halign= for a description of this property.

Python specific notes:
The object exposes a readable attribute 'halign'. This is the getter.

halign=

(1) Signature: void **halign=** (int a)

Description: Sets the horizontal alignment

Use of this method is deprecated

This is the version accepting integer values. It's provided for backward compatibility.

Python specific notes:
The object exposes a writable attribute 'halign'. This is the setter.

(2) Signature: void **halign=** (HAlign a)

Description: Sets the horizontal alignment

This property specifies how the text is aligned relative to the anchor point. This property has been introduced in version 0.22 and extended to enums in 0.28.

Python specific notes:
The object exposes a writable attribute 'halign'. This is the setter.

hash

Signature: *[const]* unsigned long **hash**

Description: Computes a hash value

Returns a hash value for the given text object. This method enables texts as hash keys.

This method has been introduced in version 0.25.

Python specific notes:
This method is also available as 'hash(object)'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

move

(1) Signature: Text **move** (const Vector distance)

Description: Moves the text by a certain distance (modifies self)

p:	The offset to move the text.
Returns:	A reference to this text object

Moves the text by a given offset and returns the moved text. Does not check for coordinate overflows.

(2) Signature: Text **move** (int dx, int dy)

Description: Moves the text by a certain distance (modifies self)

dx: The x distance to move the text.

dy: The y distance to move the text.

Returns: A reference to this text object

Moves the text by a given distance in x and y direction and returns the moved text. Does not check for coordinate overflows.

This method was introduced in version 0.23.

moved

(1) Signature: *[const]* Text **moved** (const Vector distance)

Description: Returns the text moved by a certain distance (does not modify self)

p: The offset to move the text.

Returns: The moved text.

Moves the text by a given offset and returns the moved text. Does not modify *this. Does not check for coordinate overflows.

(2) Signature: *[const]* Text **moved** (int dx, int dy)

Description: Returns the text moved by a certain distance (does not modify self)

dx: The x distance to move the text.

dy: The y distance to move the text.

Returns: The moved text.

Moves the text by a given offset and returns the moved text. Does not modify *this. Does not check for coordinate overflows.

This method was introduced in version 0.23.

new

(1) Signature: *[static]* new Text ptr **new** (const DText dtext)

Description: Creates an integer coordinate text from a floating-point coordinate text

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_dtext'.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new Text ptr **new**

Description: Default constructor

Creates a text with unit transformation and empty text.

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new Text ptr **new** (string string, const Trans trans)

Description: Constructor with string and transformation

A string and a transformation is provided to this constructor. The transformation specifies the location and orientation of the text object.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new Text ptr **new** (string string, int x, int y)

Description: Constructor with string and location

A string and a location is provided to this constructor. The location is specifies as a pair of x and y coordinates.

This method has been introduced in version 0.23.

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new Text ptr **new** (string string, const Trans trans, int height, int font)

Description: Constructor with string, transformation, text height and font

A string and a transformation is provided to this constructor. The transformation specifies the location and orientation of the text object. In addition, the text height and font can be specified.

Python specific notes:
This method is the default initializer of the object.

position

Signature: *[const]* Point **position**

Description: Gets the position of the text

This convenience method has been added in version 0.28.

size

Signature: *[const]* int **size**

Description: Gets the text height

Python specific notes:
The object exposes a readable attribute 'size'. This is the getter.

size=

Signature: void **size=** (int s)

Description: Sets the text height of this object

Python specific notes:
The object exposes a writable attribute 'size'. This is the setter.

string

Signature: *[const]* string **string**

Description: Get the text string

Python specific notes:
The object exposes a readable attribute 'string'. This is the getter.

string=

Signature: void **string=** (string text)

Description: Assign a text string to this object

Python specific notes:
The object exposes a writable attribute 'string'. This is the setter.

to_dtype

Signature: *[const]* DText **to_dtype** (double dbu = 1)

Description: Converts the text to a floating-point coordinate text

The database unit can be specified to translate the integer-coordinate text into a floating-point coordinate text in micron units. The database unit is basically a scaling factor.

This method has been introduced in version 0.25.

to_s

Signature: *[const]* string **to_s** (double dbu = 0)

Description: Converts the object to a string.

If a DBU is given, the output units will be micrometers.

The DBU argument has been added in version 0.27.6.

Python specific notes:
This method is also available as 'str(object)'.

trans

Signature: *[const]* Trans **trans**

Description: Gets the transformation

Python specific notes:
The object exposes a readable attribute 'trans'. This is the getter.

trans=

Signature: void **trans=** (const Trans t)

Description: Assign a transformation (text position and orientation) to this object

Python specific notes:
The object exposes a writable attribute 'trans'. This is the setter.

transformed

(1) Signature: *[const]* Text **transformed** (const ICplxTrans t)

Description: Transform the text with the given complex transformation

t:	The magnifying transformation to apply
Returns:	The transformed text (in this case an integer coordinate object now)

This method has been introduced in version 0.18.

(2) Signature: *[const]* Text **transformed** (const Trans t)

Description: Transforms the text with the given simple transformation

t:	The transformation to apply
Returns:	The transformed text

(3) Signature: *[const]* DText **transformed** (const CplxTrans t)

Description: Transforms the text with the given complex transformation

t:	The magnifying transformation to apply
Returns:	The transformed text (a DText now)

valign

Signature: *[const]* VAlign **valign**

Description: Gets the vertical alignment

See valign= for a description of this property.

Python specific notes:
The object exposes a readable attribute 'valign'. This is the getter.

valign=

(1) Signature: void **valign=** (int a)

Description: Sets the vertical alignment

Use of this method is deprecated

This is the version accepting integer values. It's provided for backward compatibility.

Python specific notes:

	The object exposes a writable attribute 'valign'. This is the setter. **(2) Signature**: void **valign=** (VAlign a) **Description**: Sets the vertical alignment This property specifies how the text is aligned relative to the anchor point. This property has been introduced in version 0.22 and extended to enums in 0.28. **Python specific notes:** The object exposes a writable attribute 'valign'. This is the setter.
x	**Signature**: *[const]* int **x** **Description**: Gets the x location of the text This method has been introduced in version 0.23. **Python specific notes:** The object exposes a readable attribute 'x'. This is the getter.
x=	**Signature**: void **x=** (int x) **Description**: Sets the x location of the text This method has been introduced in version 0.23. **Python specific notes:** The object exposes a writable attribute 'x'. This is the setter.
y	**Signature**: *[const]* int **y** **Description**: Gets the y location of the text This method has been introduced in version 0.23. **Python specific notes:** The object exposes a readable attribute 'y'. This is the getter.
y=	**Signature**: void **y=** (int y) **Description**: Sets the y location of the text This method has been introduced in version 0.23. **Python specific notes:** The object exposes a writable attribute 'y'. This is the setter.

4.100. API reference - Class DText

Notation used in Ruby API documentation

Module: db

Description: A text object

A text object has a point (location), a text, a text transformation, a text size and a font id. Text size and font id are provided to be be able to render the text correctly. Text objects are used as labels (i.e. for pins) or to indicate a particular position.

The DText class uses floating-point coordinates. A class that operates with integer coordinates is Text.

See The Database API for more details about the database objects.

Public constructors

new DText ptr	**new**	(const Text Text)	Creates a floating-point coordinate text from an integer coordinate text
new DText ptr	**new**		Default constructor
new DText ptr	**new**	(string string, const DTrans trans)	Constructor with string and transformation
new DText ptr	**new**	(string string, double x, double y)	Constructor with string and location
new DText ptr	**new**	(string string, const DTrans trans, double height, int font)	Constructor with string, transformation, text height and font

Public methods

[const]	bool	**!=**	(const DText text)	Inequality
[const]	bool	**<**	(const DText t)	Less operator
[const]	bool	**==**	(const DText text)	Equality
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.

	void	**assign**	(const DText other)	Assigns another object to self
[const]	DBox	**bbox**		Gets the bounding box of the text
[const]	new DText ptr	**dup**		Creates a copy of self
[const]	int	**font**		Gets the font number
	void	**font=**	(int f)	Sets the font number
[const]	HAlign	**halign**		Gets the horizontal alignment
	void	**halign=**	(HAlign a)	Sets the horizontal alignment
[const]	unsigned long	**hash**		Computes a hash value
	DText	**move**	(const DVector distance)	Moves the text by a certain distance (modifies self)
	DText	**move**	(double dx, double dy)	Moves the text by a certain distance (modifies self)
[const]	DText	**moved**	(const DVector distance)	Returns the text moved by a certain distance (does not modify self)
[const]	DText	**moved**	(double dx, double dy)	Returns the text moved by a certain distance (does not modify self)
[const]	DPoint	**position**		Gets the position of the text
[const]	double	**size**		Gets the text height
	void	**size=**	(double s)	Sets the text height of this object
[const]	string	**string**		Get the text string
	void	**string=**	(string text)	Assign a text string to this object
[const]	Text	**to_itype**	(double dbu = 1)	Converts the text to an integer coordinate text
[const]	string	**to_s**	(double dbu = 0)	Converts the object to a string.
[const]	DTrans	**trans**		Gets the transformation
	void	**trans=**	(const DTrans t)	Assign a transformation (text position and orientation) to this object
[const]	Text	**transformed**	(const VCplxTrans t)	Transforms the text with the given complex transformation
[const]	DText	**transformed**	(const DTrans t)	Transforms the text with the given simple transformation
[const]	DText	**transformed**	(const DCplxTrans t)	Transforms the text with the given complex transformation
[const]	VAlign	**valign**		Gets the vertical alignment

	void	valign=	(VAlign a)	Sets the vertical alignment
[const]	double	x		Gets the x location of the text
	void	x=	(double x)	Sets the x location of the text
[const]	double	y		Gets the y location of the text
	void	y=	(double y)	Sets the y location of the text

Public static methods and constants

[static,const]	HAlign	HAlignCenter		Centered horizontal alignment
[static,const]	HAlign	HAlignLeft		Left horizontal alignment
[static,const]	HAlign	HAlignRight		Right horizontal alignment
[static,const]	HAlign	NoHAlign		Undefined horizontal alignment
[static,const]	VAlign	NoVAlign		Undefined vertical alignment
[static,const]	VAlign	VAlignBottom		Bottom vertical alignment
[static,const]	VAlign	VAlignCenter		Centered vertical alignment
[static,const]	VAlign	VAlignTop		Top vertical alignment
	new DText ptr	from_s	(string s)	Creates an object from a string

Deprecated methods (protected, public, static, non-static and constructors)

	void	create		Use of this method is deprecated. Use _create instead
	void	destroy		Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?		Use of this method is deprecated. Use _destroyed? instead
	void	halign=	(int a)	Use of this method is deprecated
[const]	bool	is_const_object?		Use of this method is deprecated. Use _is_const_object? instead
	void	valign=	(int a)	Use of this method is deprecated

Detailed description

!=

Signature: *[const]* bool **!=** (const DText text)
Description: Inequality

Return true, if this text object and the given text are not equal

<	**Signature**: *[const]* bool **<** (const DText t) **Description**: Less operator **t**: The object to compare against This operator is provided to establish some, not necessarily a certain sorting order
==	**Signature**: *[const]* bool **==** (const DText text) **Description**: Equality Return true, if this text object and the given text are equal
HAlignCenter	**Signature**: *[static,const]* HAlign **HAlignCenter** **Description**: Centered horizontal alignment **Python specific notes:** The object exposes a readable attribute 'HAlignCenter'. This is the getter.
HAlignLeft	**Signature**: *[static,const]* HAlign **HAlignLeft** **Description**: Left horizontal alignment **Python specific notes:** The object exposes a readable attribute 'HAlignLeft'. This is the getter.
HAlignRight	**Signature**: *[static,const]* HAlign **HAlignRight** **Description**: Right horizontal alignment **Python specific notes:** The object exposes a readable attribute 'HAlignRight'. This is the getter.
NoHAlign	**Signature**: *[static,const]* HAlign **NoHAlign** **Description**: Undefined horizontal alignment **Python specific notes:** The object exposes a readable attribute 'NoHAlign'. This is the getter.
NoVAlign	**Signature**: *[static,const]* VAlign **NoVAlign** **Description**: Undefined vertical alignment **Python specific notes:** The object exposes a readable attribute 'NoVAlign'. This is the getter.
VAlignBottom	**Signature**: *[static,const]* VAlign **VAlignBottom** **Description**: Bottom vertical alignment **Python specific notes:** The object exposes a readable attribute 'VAlignBottom'. This is the getter.
VAlignCenter	**Signature**: *[static,const]* VAlign **VAlignCenter** **Description**: Centered vertical alignment **Python specific notes:** The object exposes a readable attribute 'VAlignCenter'. This is the getter.

VAlignTop

Signature: *[static,const]* VAlign **VAlignTop**

Description: Top vertical alignment

Python specific notes:
The object exposes a readable attribute 'VAlignTop'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const DText other)

Description: Assigns another object to self

bbox

Signature: *[const]* DBox **bbox**

Description: Gets the bounding box of the text

The bounding box of the text is a single point - the location of the text. Both points of the box are identical.

This method has been added in version 0.28.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new DText ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

font

Signature: *[const]* int **font**

Description: Gets the font number

See font= for a description of this property.

Python specific notes:
The object exposes a readable attribute 'font'. This is the getter.

font=

Signature: void **font=** (int f)

Description: Sets the font number

The font number does not play a role for KLayout. This property is provided for compatibility with other systems which allow using different fonts for the text objects.

Python specific notes:
The object exposes a writable attribute 'font'. This is the setter.

from_s

Signature: *[static]* new DText ptr **from_s** (string s)

Description: Creates an object from a string

Creates the object from a string representation (as returned by to_s)

This method has been added in version 0.23.

halign

Signature: *[const]* HAlign **halign**

Description: Gets the horizontal alignment

See halign= for a description of this property.

Python specific notes:
The object exposes a readable attribute 'halign'. This is the getter.

halign=

(1) Signature: void **halign=** (int a)

Description: Sets the horizontal alignment

Use of this method is deprecated

This is the version accepting integer values. It's provided for backward compatibility.

Python specific notes:
The object exposes a writable attribute 'halign'. This is the setter.

(2) Signature: void **halign=** (HAlign a)

Description: Sets the horizontal alignment

This property specifies how the text is aligned relative to the anchor point. This property has been introduced in version 0.22 and extended to enums in 0.28.

Python specific notes:
The object exposes a writable attribute 'halign'. This is the setter.

hash

Signature: *[const]* unsigned long **hash**

Description: Computes a hash value

Returns a hash value for the given text object. This method enables texts as hash keys.

This method has been introduced in version 0.25.

Python specific notes:
This method is also available as 'hash(object)'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

move

(1) Signature: DText **move** (const DVector distance)

Description: Moves the text by a certain distance (modifies self)

p:	The offset to move the text.
Returns:	A reference to this text object

Moves the text by a given offset and returns the moved text. Does not check for coordinate overflows.

(2) Signature: DText **move** (double dx, double dy)

Description: Moves the text by a certain distance (modifies self)

dx:	The x distance to move the text.
dy:	The y distance to move the text.
Returns:	A reference to this text object

Moves the text by a given distance in x and y direction and returns the moved text. Does not check for coordinate overflows.

This method was introduced in version 0.23.

moved

(1) Signature: *[const]* DText **moved** (const DVector distance)

Description: Returns the text moved by a certain distance (does not modify self)

p:	The offset to move the text.
Returns:	The moved text.

Moves the text by a given offset and returns the moved text. Does not modify *this. Does not check for coordinate overflows.

(2) Signature: *[const]* DText **moved** (double dx, double dy)

Description: Returns the text moved by a certain distance (does not modify self)

dx:	The x distance to move the text.
dy:	The y distance to move the text.
Returns:	The moved text.

Moves the text by a given offset and returns the moved text. Does not modify *this. Does not check for coordinate overflows.

This method was introduced in version 0.23.

new

(1) Signature: *[static]* new DText ptr **new** (const Text Text)

Description: Creates a floating-point coordinate text from an integer coordinate text

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_itext'.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new DText ptr **new**

Description: Default constructor

Creates a text with unit transformation and empty text.

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new DText ptr **new** (string string, const DTrans trans)

Description: Constructor with string and transformation

A string and a transformation is provided to this constructor. The transformation specifies the location and orientation of the text object.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new DText ptr **new** (string string, double x, double y)

Description: Constructor with string and location

A string and a location is provided to this constructor. The location is specifies as a pair of x and y coordinates.

This method has been introduced in version 0.23.

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new DText ptr **new** (string string, const DTrans trans, double height, int font)

Description: Constructor with string, transformation, text height and font

A string and a transformation is provided to this constructor. The transformation specifies the location and orientation of the text object. In addition, the text height and font can be specified.

Python specific notes:
This method is the default initializer of the object.

position

Signature: *[const]* DPoint **position**

Description: Gets the position of the text

This convenience method has been added in version 0.28.

size

Signature: *[const]* double **size**

Description: Gets the text height

Python specific notes:
The object exposes a readable attribute 'size'. This is the getter.

size=

Signature: void **size=** (double s)

Description: Sets the text height of this object

Python specific notes:
The object exposes a writable attribute 'size'. This is the setter.

string

Signature: *[const]* string **string**

Description: Get the text string

Python specific notes:
The object exposes a readable attribute 'string'. This is the getter.

string=

Signature: void **string=** (string text)

Description: Assign a text string to this object

Python specific notes:
The object exposes a writable attribute 'string'. This is the setter.

to_itype

Signature: *[const]* Text **to_itype** (double dbu = 1)

Description: Converts the text to an integer coordinate text

The database unit can be specified to translate the floating-point coordinate Text in micron units to an integer-coordinate text in database units. The text's coordinates will be divided by the database unit.

This method has been introduced in version 0.25.

to_s

Signature: *[const]* string **to_s** (double dbu = 0)

Description: Converts the object to a string.

If a DBU is given, the output units will be micrometers.

The DBU argument has been added in version 0.27.6.

Python specific notes:
This method is also available as 'str(object)'.

trans

Signature: *[const]* DTrans **trans**

Description: Gets the transformation

Python specific notes:
The object exposes a readable attribute 'trans'. This is the getter.

trans=

Signature: void **trans=** (const DTrans t)

Description: Assign a transformation (text position and orientation) to this object

Python specific notes:
The object exposes a writable attribute 'trans'. This is the setter.

transformed

(1) Signature: *[const]* Text **transformed** (const VCplxTrans t)

Description: Transforms the text with the given complex transformation

t:	The magnifying transformation to apply
Returns:	The transformed text (in this case an integer coordinate text)

This method has been introduced in version 0.25.

(2) Signature: *[const]* DText **transformed** (const DTrans t)

Description: Transforms the text with the given simple transformation

t:	The transformation to apply
Returns:	The transformed text

(3) Signature: *[const]* DText **transformed** (const DCplxTrans t)

Description: Transforms the text with the given complex transformation

t:	The magnifying transformation to apply
Returns:	The transformed text (a DText now)

valign

Signature: *[const]* VAlign **valign**

Description: Gets the vertical alignment

See valign= for a description of this property.

Python specific notes:
The object exposes a readable attribute 'valign'. This is the getter.

valign=

(1) Signature: void **valign=** (int a)

Description: Sets the vertical alignment

Use of this method is deprecated

This is the version accepting integer values. It's provided for backward compatibility.

Python specific notes:
The object exposes a writable attribute 'valign'. This is the setter.

(2) Signature: void **valign=** (VAlign a)

Description: Sets the vertical alignment

This property specifies how the text is aligned relative to the anchor point. This property has been introduced in version 0.22 and extended to enums in 0.28.

Python specific notes:
The object exposes a writable attribute 'valign'. This is the setter.

x

Signature: *[const]* double **x**

Description: Gets the x location of the text

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a readable attribute 'x'. This is the getter.

x=

Signature: void **x=** (double x)

Description: Sets the x location of the text

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'x'. This is the setter.

y

Signature: *[const]* double **y**

Description: Gets the y location of the text

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a readable attribute 'y'. This is the getter.

y=

Signature: void **y=** (double y)

Description: Sets the y location of the text

This method has been introduced in version 0.23.

Python specific notes:
The object exposes a writable attribute 'y'. This is the setter.

4.101. API reference - Class HAlign

Notation used in Ruby API documentation

Module: db

Description: This class represents the horizontal alignment modes.

This enum has been introduced in version 0.28.

Public constructors

new HAlign ptr	**new**	(int i)		Creates an enum from an integer value
new HAlign ptr	**new**	(string s)		Creates an enum from a string value

Public methods

[const]	bool	**!=**	(const HAlign other)	Compares two enums for inequality
[const]	bool	**!=**	(int other)	Compares an enum with an integer for inequality
[const]	bool	**<**	(const HAlign other)	Returns true if the first enum is less (in the enum symbol order) than the second
[const]	bool	**<**	(int other)	Returns true if the enum is less (in the enum symbol order) than the integer value
[const]	bool	**==**	(const HAlign other)	Compares two enums
[const]	bool	**==**	(int other)	Compares an enum with an integer value
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const HAlign other)	Assigns another object to self
[const]	new HAlign ptr	**dup**		Creates a copy of self
[const]	int	**hash**		Gets the hash value from the enum
[const]	string	**inspect**		Converts an enum to a visual string

[const]	int	**to_i**	Gets the integer value from the enum
[const]	string	**to_s**	Gets the symbolic string from an enum

Public static methods and constants

[static,const]	HAlign	**HAlignCenter**	Centered horizontal alignment
[static,const]	HAlign	**HAlignLeft**	Left horizontal alignment
[static,const]	HAlign	**HAlignRight**	Right horizontal alignment
[static,const]	HAlign	**NoHAlign**	Undefined horizontal alignment

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

!=

(1) Signature: *[const]* bool **!=** (const HAlign other)
Description: Compares two enums for inequality

(2) Signature: *[const]* bool **!=** (int other)
Description: Compares an enum with an integer for inequality

<

(1) Signature: *[const]* bool **<** (const HAlign other)
Description: Returns true if the first enum is less (in the enum symbol order) than the second

(2) Signature: *[const]* bool **<** (int other)
Description: Returns true if the enum is less (in the enum symbol order) than the integer value

==

(1) Signature: *[const]* bool **==** (const HAlign other)
Description: Compares two enums

(2) Signature: *[const]* bool **==** (int other)
Description: Compares an enum with an integer value

HAlignCenter

Signature: *[static,const]* HAlign **HAlignCenter**
Description: Centered horizontal alignment
Python specific notes:

The object exposes a readable attribute 'HAlignCenter'. This is the getter.

HAlignLeft

Signature: *[static,const]* HAlign **HAlignLeft**

Description: Left horizontal alignment

Python specific notes:
The object exposes a readable attribute 'HAlignLeft'. This is the getter.

HAlignRight

Signature: *[static,const]* HAlign **HAlignRight**

Description: Right horizontal alignment

Python specific notes:
The object exposes a readable attribute 'HAlignRight'. This is the getter.

NoHAlign

Signature: *[static,const]* HAlign **NoHAlign**

Description: Undefined horizontal alignment

Python specific notes:
The object exposes a readable attribute 'NoHAlign'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const HAlign other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new HAlign ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

hash

Signature: *[const]* int **hash**

Description: Gets the hash value from the enum

Python specific notes:
This method is also available as 'hash(object)'.

inspect

Signature: *[const]* string **inspect**

Description: Converts an enum to a visual string

Python specific notes:

	This method is also available as 'repr(object)'.
is_const_object?	**Signature**: *[const]* bool **is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.
new	**(1) Signature**: *[static]* new HAlign ptr **new** (int i) **Description**: Creates an enum from an integer value **Python specific notes:** This method is the default initializer of the object. **(2) Signature**: *[static]* new HAlign ptr **new** (string s) **Description**: Creates an enum from a string value **Python specific notes:** This method is the default initializer of the object.
to_i	**Signature**: *[const]* int **to_i** **Description**: Gets the integer value from the enum **Python specific notes:** This method is also available as 'int(object)'.
to_s	**Signature**: *[const]* string **to_s** **Description**: Gets the symbolic string from an enum **Python specific notes:** This method is also available as 'str(object)'.

4.102. API reference - Class VAlign

Notation used in Ruby API documentation

Module: db

Description: This class represents the vertical alignment modes.

This enum has been introduced in version 0.28.

Public constructors

new VAlign ptr	**new**	(int i)		Creates an enum from an integer value
new VAlign ptr	**new**	(string s)		Creates an enum from a string value

Public methods

[const]	bool	**!=**	(const VAlign other)	Compares two enums for inequality
[const]	bool	**!=**	(int other)	Compares an enum with an integer for inequality
[const]	bool	**<**	(const VAlign other)	Returns true if the first enum is less (in the enum symbol order) than the second
[const]	bool	**<**	(int other)	Returns true if the enum is less (in the enum symbol order) than the integer value
[const]	bool	**==**	(const VAlign other)	Compares two enums
[const]	bool	**==**	(int other)	Compares an enum with an integer value
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const VAlign other)	Assigns another object to self
[const]	new VAlign ptr	**dup**		Creates a copy of self
[const]	int	**hash**		Gets the hash value from the enum
[const]	string	**inspect**		Converts an enum to a visual string

[const]	int	**to_i**	Gets the integer value from the enum
[const]	string	**to_s**	Gets the symbolic string from an enum

Public static methods and constants

[static,const]	VAlign	**NoVAlign**	Undefined vertical alignment
[static,const]	VAlign	**VAlignBottom**	Bottom vertical alignment
[static,const]	VAlign	**VAlignCenter**	Centered vertical alignment
[static,const]	VAlign	**VAlignTop**	Top vertical alignment

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

!=

(1) Signature: *[const]* bool **!=** (const VAlign other)
Description: Compares two enums for inequality

(2) Signature: *[const]* bool **!=** (int other)
Description: Compares an enum with an integer for inequality

<

(1) Signature: *[const]* bool **<** (const VAlign other)
Description: Returns true if the first enum is less (in the enum symbol order) than the second

(2) Signature: *[const]* bool **<** (int other)
Description: Returns true if the enum is less (in the enum symbol order) than the integer value

==

(1) Signature: *[const]* bool **==** (const VAlign other)
Description: Compares two enums

(2) Signature: *[const]* bool **==** (int other)
Description: Compares an enum with an integer value

NoVAlign

Signature: *[static,const]* VAlign **NoVAlign**
Description: Undefined vertical alignment
Python specific notes:

The object exposes a readable attribute 'NoVAlign'. This is the getter.

VAlignBottom

Signature: *[static,const]* VAlign **VAlignBottom**

Description: Bottom vertical alignment

Python specific notes:
The object exposes a readable attribute 'VAlignBottom'. This is the getter.

VAlignCenter

Signature: *[static,const]* VAlign **VAlignCenter**

Description: Centered vertical alignment

Python specific notes:
The object exposes a readable attribute 'VAlignCenter'. This is the getter.

VAlignTop

Signature: *[static,const]* VAlign **VAlignTop**

Description: Top vertical alignment

Python specific notes:
The object exposes a readable attribute 'VAlignTop'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const VAlign other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new VAlign ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

hash

Signature: *[const]* int **hash**

Description: Gets the hash value from the enum

Python specific notes:
This method is also available as 'hash(object)'.

inspect

Signature: *[const]* string **inspect**

Description: Converts an enum to a visual string

Python specific notes:

	This method is also available as 'repr(object)'.
is_const_object?	**Signature**: *[const]* bool **is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.
new	**(1) Signature**: *[static]* new VAlign ptr **new** (int i) **Description**: Creates an enum from an integer value **Python specific notes:** This method is the default initializer of the object. **(2) Signature**: *[static]* new VAlign ptr **new** (string s) **Description**: Creates an enum from a string value **Python specific notes:** This method is the default initializer of the object.
to_i	**Signature**: *[const]* int **to_i** **Description**: Gets the integer value from the enum **Python specific notes:** This method is also available as 'int(object)'.
to_s	**Signature**: *[const]* string **to_s** **Description**: Gets the symbolic string from an enum **Python specific notes:** This method is also available as 'str(object)'.

4.103. API reference - Class TileOutputReceiver

Notation used in Ruby API documentation

Module: db

Description: A receiver abstraction for the tiling processor.

Class hierarchy: TileOutputReceiver

The tiling processor (TilingProcessor) is a framework for executing sequences of operations on tiles of a layout or multiple layouts. The TileOutputReceiver class is used to specify an output channel for the tiling processor. See TilingProcessor#output for more details.

This class has been introduced in version 0.23.

Public constructors

new TileOutputReceiver ptr	**new**		Creates a new object of this class

Public methods

	void	**_assign**	(const TileOutputReceiver other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new TileOutputReceiver ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const TileOutputReceiver other)	Assigns another object to self
[virtual]	void	**begin**	(unsigned long nx, unsigned long ny, const DPoint p0, double dx, double dy, const DBox frame)	Initiates the delivery
[const]	new TileOutputReceiver ptr	**dup**		Creates a copy of self

[virtual]	void	**finish**	(bool success)	Indicates the end of the execution
[const]	TilingProcessor ptr	**processor**		Gets the processor the receiver is attached to
[virtual]	void	**put**	(unsigned long ix, unsigned long iy, const Box tile, variant obj, double dbu, bool clip)	Delivers data for one tile

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_assign

Signature: void **_assign** (const TileOutputReceiver other)

Description: Assigns another object to self

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_dup

Signature: *[const]* new TileOutputReceiver ptr **_dup**

Description: Creates a copy of self

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const TileOutputReceiver other)

Description: Assigns another object to self

begin

Signature: *[virtual]* void **begin** (unsigned long nx, unsigned long ny, const DPoint p0, double dx, double dy, const DBox frame)

Description: Initiates the delivery

nx:	The number of tiles in x direction
ny:	The number of tiles in y direction
p0:	The initial point
dx:	The tile's x dimension
dy:	The tile's y dimension
frame:	The overall frame that is the basis of the tiling

This method is called before the first tile delivers its data.

The tile's coordinates will be p0+(ix*dx,iy*dy)..p0+((ix+1)*dx,(iy+1)*dy) where ix=0..nx-1, iy=0..ny-1.

All coordinates are given in micron. If tiles are not used, nx and ny are 0.

The frame parameter has been added in version 0.25.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new TileOutputReceiver ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

finish

Signature: *[virtual]* void **finish** (bool success)

Description: Indicates the end of the execution

This method is called when the tiling processor has finished the last tile and script item. The success flag is set to true, if every tile has finished successfully. Otherwise, this value is false.

The success flag has been added in version 0.25.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new TileOutputReceiver ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

processor

Signature: *[const]* TilingProcessor ptr **processor**

Description: Gets the processor the receiver is attached to

This attribute is set before begin and can be nil if the receiver is not attached to a processor.

This method has been introduced in version 0.25.

put

Signature: *[virtual]* void **put** (unsigned long ix, unsigned long iy, const Box tile, variant obj, double dbu, bool clip)

Description: Delivers data for one tile

ix:	The x index of the tile
iy:	The y index of the tile

tile:	The tile's box
obj:	The object which is delivered
dbu:	The database unit
clip:	True if clipping at the tile box is requested

When the script's "_output" function is called, the data will be delivered through this method. "obj" is the data passed as the second argument to _output. The interpretation of the object remains subject to the implementation.

The obj and clip parameters are taken from the _output method call inside the script. If clip is set to true, this usually means that output shall be clipped to the tile.

4.104. API reference - Class TilingProcessor

Notation used in Ruby API documentation

Module: db

Description: A processor for layout which distributes tasks over tiles

The tiling processor executes one or several scripts on one or multiple layouts providing a tiling scheme. In that scheme, the processor divides the original layout into rectangular tiles and executes the scripts on each tile separately. The tiling processor allows one to specify multiple, independent scripts which are run separately on each tile. It can make use of multi-core CPU's by supporting multiple threads running the tasks in parallel (with respect to tiles and scripts).

Tiling a optional - if no tiles are specified, the tiling processing basically operates flat and parallelization extends to the scripts only.

Tiles can be overlapping to gather input from neighboring tiles into the current tile. In order to provide that feature, a border can be specified which gives the amount by which the search region is extended beyond the border of the tile. To specify the border, use the TilingProcessor#tile_border method.

The basis of the tiling processor are Region objects and expressions. Expressions are a built-in simple language to form simple scripts. Expressions allow access to the objects and methods built into KLayout. Each script can consist of multiple operations. Scripts are specified using TilingProcessor#queue.

Input is provided to the script through variables holding a Region object each. From outside the tiling processor, input is specified with the TilingProcessor#input method. This method is given a name and a RecursiveShapeIterator object which delivers the data for the input. On the script side, a Region object is provided through a variable named like the first argument of the "input" method.

Inside the script the following functions are provided:

- "_dbu" delivers the database unit used for the computations
- "_tile" delivers a region containing a mask for the tile (a rectangle) or nil if no tiling is used
- "_output" is used to deliver output (see below)

Output can be obtained from the tiling processor by registering a receiver with a channel. A channel is basically a name. Inside the script, the name describes a variable which can be used as the first argument of the "_output" function to identify the channel. A channel is registers using the TilingProcessor#output method. Beside the name, a receiver must be specified. A receiver is either another layout (a cell of that), a report database or a custom receiver implemented through the TileOutputReceiver class.

The "_output" function expects two or three parameters: one channel id (the variable that was defined by the name given in the output method call) and an object to output (a Region, Edges, EdgePairs or a geometrical primitive such as Polygon or Box). In addition, a boolean argument can be given indicating whether clipping at the tile shall be applied. If clipping is requested (the default), the shapes will be clipped at the tile's box.

The tiling can be specified either through a tile size, a tile number or both. If a tile size is specified with the TilingProcessor#tile_size method, the tiling processor will compute the number of tiles required. If the tile count is given (through TilingProcessor#tiles), the tile size will be computed. If both are given, the tiling array is fixed and the array is centered around the original layout's center. If the tiling origin is given as well, the tiling processor will use the given array without any modifications.

Once the tiling processor has been set up, the operation can be launched using TilingProcessor#execute.

This is some sample code. It performs two XOR operations between two layouts and delivers the results to a report database:

```
ly1 = ... # first layout
ly2 = ... # second layout

rdb = RBA::ReportDatabase::new("xor")
output_cell = rdb.create_cell(ly1.top_cell.name)
output_cat1 = rbd.create_category("XOR 1-10")
output_cat2 = rbd.create_category("XOR 2-11")

tp = RBA::TilingProcessor::new
tp.input("a1", ly1, ly1.top_cell.cell_index, RBA::LayerInfo::new(1, 0))
tp.input("a2", ly1, ly1.top_cell.cell_index, RBA::LayerInfo::new(2, 0))
tp.input("b1", ly2, ly2.top_cell.cell_index, RBA::LayerInfo::new(11, 0))
tp.input("b2", ly2, ly2.top_cell.cell_index, RBA::LayerInfo::new(12, 0))
```

```
tp.output("o1", rdb, output_cell, output_cat1)
tp.output("o2", rdb, output_cell, output_cat2)
tp.queue("_output(o1, a1 ^ b1)")
tp.queue("_output(o2, a2 ^ b2)")
tp.tile_size(50.0, 50.0)
tp.execute("Job description")
```

This class has been introduced in version 0.23.

Public constructors

new TilingProcessor ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const TilingProcessor other)	Assigns another object to self
[const]	double	**dbu**		Gets the database unit under which the computations will be done
	void	**dbu=**	(double u)	Sets the database unit under which the computations will be done
[const]	new TilingProcessor ptr	**dup**		Creates a copy of self
	void	**execute**	(string desc)	Runs the job
	void	**frame=**	(const DBox frame)	Sets the layout frame
	void	**input**	(string name, const RecursiveShapeIterator iter)	Specifies input for the tiling processor
	void	**input**	(string name, const RecursiveShapeIterator iter, const ICplxTrans trans)	Specifies input for the tiling processor
	void	**input**	(string name, const Layout layout,	Specifies input for the tiling processor

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead

[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const TilingProcessor other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

dbu

Signature: *[const]* double **dbu**

Description: Gets the database unit under which the computations will be done

Python specific notes:
The object exposes a readable attribute 'dbu'. This is the getter.

dbu=

Signature: void **dbu=** (double u)

Description: Sets the database unit under which the computations will be done

All data used within the scripts will be brought to that database unit. If none is given it will be the database unit of the first layout given or 1nm if no layout is specified.

Python specific notes:
The object exposes a writable attribute 'dbu'. This is the setter.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new TilingProcessor ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

execute

Signature: void **execute** (string desc)

Description: Runs the job

This method will initiate execution of the queued scripts, once for every tile. The desc is a text shown in the progress bar for example.

frame=

Signature: void **frame=** (const DBox frame)

Description: Sets the layout frame

The layout frame is the box (in micron units) taken into account for computing the tiles if the tile counts are not given. If the layout frame is not set or set to an empty box, the processor will try to derive the frame from the given inputs.

This method has been introduced in version 0.25.

Python specific notes:
The object exposes a writable attribute 'frame'. This is the setter.

input

(1) Signature: void **input** (string name, const RecursiveShapeIterator iter)

Description: Specifies input for the tiling processor

This method will establish an input channel for the processor. This version receives input from a recursive shape iterator, hence from a hierarchy of shapes from a layout.

The name specifies the variable under which the input can be used in the scripts.

(2) Signature: void **input** (string name, const RecursiveShapeIterator iter, const ICplxTrans trans)

Description: Specifies input for the tiling processor

This method will establish an input channel for the processor. This version receives input from a recursive shape iterator, hence from a hierarchy of shapes from a layout. In addition, a transformation can be specified which will be applied to the shapes before they are used.

The name specifies the variable under which the input can be used in the scripts.

(3) Signature: void **input** (string name, const Layout layout, unsigned int cell_index, const LayerInfo lp)

Description: Specifies input for the tiling processor

This method will establish an input channel for the processor. This version receives input from a layout and the hierarchy below the cell with the given cell index. "lp" is a LayerInfo object specifying the input layer.

The name specifies the variable under which the input can be used in the scripts.

(4) Signature: void **input** (string name, const Layout layout, unsigned int cell_index, unsigned int layer)

Description: Specifies input for the tiling processor

This method will establish an input channel for the processor. This version receives input from a layout and the hierarchy below the cell with the given cell index. "layer" is the layer index of the input layer.

The name specifies the variable under which the input can be used in the scripts.

(5) Signature: void **input** (string name, const Layout layout, unsigned int cell_index, const LayerInfo lp, const ICplxTrans trans)

Description: Specifies input for the tiling processor

This method will establish an input channel for the processor. This version receives input from a layout and the hierarchy below the cell with the given cell index. "lp" is a LayerInfo object specifying the input layer. In addition, a transformation can be specified which will be applied to the shapes before they are used.

The name specifies the variable under which the input can be used in the scripts.

(6) Signature: void **input** (string name, const Layout layout, unsigned int cell_index, unsigned int layer, const ICplxTrans trans)

Description: Specifies input for the tiling processor

This method will establish an input channel for the processor. This version receives input from a layout and the hierarchy below the cell with the given cell index. "layer" is the layer index of the input layer. In addition, a transformation can be specified which will be applied to the shapes before they are used.

The name specifies the variable under which the input can be used in the scripts.

(7) Signature: void **input** (string name, const Region region)

Description: Specifies input for the tiling processor

This method will establish an input channel for the processor. This version receives input from a Region object. Regions don't always come with a database unit, hence a database unit should be specified with the dbu= method unless a layout object is specified as input too.

Caution: the Region object must stay valid during the lifetime of the tiling processor. Take care to store it in a variable to prevent early destruction of the Region object. Not doing so may crash the application.

The name specifies the variable under which the input can be used in the scripts.

(8) Signature: void **input** (string name, const Region region, const ICplxTrans trans)

Description: Specifies input for the tiling processor

This method will establish an input channel for the processor. This version receives input from a Region object. Regions don't always come with a database unit, hence a database unit should be specified with the dbu= method unless a layout object is specified as input too.

Caution: the Region object must stay valid during the lifetime of the tiling processor. Take care to store it in a variable to prevent early destruction of the Region object. Not doing so may crash the application.

The name specifies the variable under which the input can be used in the scripts. This variant allows one to specify an additional transformation too. It has been introduced in version 0.23.2.

(9) Signature: void **input** (string name, const Edges edges)

Description: Specifies input for the tiling processor

This method will establish an input channel for the processor. This version receives input from an Edges object. Edge collections don't always come with a database unit, hence a database unit should be specified with the dbu= method unless a layout object is specified as input too.

Caution: the Edges object must stay valid during the lifetime of the tiling processor. Take care to store it in a variable to prevent early destruction of the Edges object. Not doing so may crash the application.

The name specifies the variable under which the input can be used in the scripts.

(10) Signature: void **input** (string name, const Edges edges, const ICplxTrans trans)

Description: Specifies input for the tiling processor

This method will establish an input channel for the processor. This version receives input from an Edges object. Edge collections don't always come with a database unit, hence a database unit should be specified with the dbu= method unless a layout object is specified as input too.

Caution: the Edges object must stay valid during the lifetime of the tiling processor. Take care to store it in a variable to prevent early destruction of the Edges object. Not doing so may crash the application.

The name specifies the variable under which the input can be used in the scripts. This variant allows one to specify an additional transformation too. It has been introduced in version 0.23.2.

(11) Signature: void **input** (string name, const EdgePairs edge_pairs)

Description: Specifies input for the tiling processor

This method will establish an input channel for the processor. This version receives input from an EdgePairs object. Edge pair collections don't always come with a database unit, hence a database unit should be specified with the dbu= method unless a layout object is specified as input too.

Caution: the EdgePairs object must stay valid during the lifetime of the tiling processor. Take care to store it in a variable to prevent early destruction of the EdgePairs object. Not doing so may crash the application.

The name specifies the variable under which the input can be used in the scripts. This variant has been introduced in version 0.27.

(12) Signature: void **input** (string name, const EdgePairs edge_pairs, const ICplxTrans trans)

Description: Specifies input for the tiling processor

This method will establish an input channel for the processor. This version receives input from an EdgePairs object. Edge pair collections don't always come with a database unit, hence a database unit should be specified with the dbu= method unless a layout object is specified as input too.

Caution: the EdgePairs object must stay valid during the lifetime of the tiling processor. Take care to store it in a variable to prevent early destruction of the EdgePairs object. Not doing so may crash the application.

The name specifies the variable under which the input can be used in the scripts. This variant has been introduced in version 0.27.

(13) Signature: void **input** (string name, const Texts texts)

Description: Specifies input for the tiling processor

This method will establish an input channel for the processor. This version receives input from an Texts object. Text collections don't always come with a database unit, hence a database unit should be specified with the dbu= method unless a layout object is specified as input too.

Caution: the Texts object must stay valid during the lifetime of the tiling processor. Take care to store it in a variable to prevent early destruction of the Texts object. Not doing so may crash the application.

The name specifies the variable under which the input can be used in the scripts. This variant has been introduced in version 0.27.

(14) Signature: void **input** (string name, const Texts texts, const ICplxTrans trans)

Description: Specifies input for the tiling processor

This method will establish an input channel for the processor. This version receives input from an Texts object. Text collections don't always come with a database unit, hence a database unit should be specified with the dbu= method unless a layout object is specified as input too.

Caution: the Texts object must stay valid during the lifetime of the tiling processor. Take care to store it in a variable to prevent early destruction of the Texts object. Not doing so may crash the application.

The name specifies the variable under which the input can be used in the scripts. This variant has been introduced in version 0.27.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new TilingProcessor ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

output

(1) Signature: void **output** (string name, TileOutputReceiver ptr rec)

Description: Specifies output for the tiling processor

This method will establish an output channel for the processor. For that it registers an output receiver which will receive data from the scripts. The scripts call the _output function to deliver data. "name" will be name of the variable which must be passed to the first argument of the _output function in order to address this channel.

Please note that the tiling processor will destroy the receiver object when it is freed itself. Hence if you need to address the receiver object later, make sure that the processor is still alive, i.e. by assigning the object to a variable.

The following code uses the output receiver. It takes the shapes of a layer from a layout, computes the area of each tile and outputs the area to the custom receiver:

```
layout = ... # the layout
cell = ... # the top cell's index
layout = ... # the input layer

class MyReceiver < RBA::TileOutputReceiver
  def put(ix, iy, tile, obj, dbu, clip)
    puts "got area for tile #{ix+1},#{iy+1}: #{obj.to_s}"
  end
end

tp = RBA::TilingProcessor::new

# register the custom receiver
tp.output("my_receiver", MyReceiver::new)
tp.input("the_input", layout.begin_shapes(cell, layer))
tp.tile_size(100, 100)  # 100x100 um tile size
# The script clips the input at the tile and computes the (merged) area:
tp.queue("_output(my_receiver, (the_input & _tile).area)")
tp.execute("Job description")
```

(2) Signature: void **output** (string name, Layout layout, unsigned int cell, const LayerInfo lp)

Description: Specifies output to a layout layer

name:	The name of the channel
layout:	The layout to which the data is sent
cell:	The index of the cell to which the data is sent
lp:	The layer specification where the output will be sent to

This method will establish an output channel to a layer in a layout. The output sent to that channel will be put into the specified layer and cell. In this version, the layer is specified through a LayerInfo object, i.e. layer and datatype number. If no such layer exists, it will be created.

The name is the name which must be used in the _output function of the scripts in order to address that channel.

(3) Signature: void **output** (string name, Layout layout, unsigned int cell, unsigned int layer_index)

Description: Specifies output to a layout layer

name:	The name of the channel
layout:	The layout to which the data is sent
cell:	The index of the cell to which the data is sent

layer_index: The layer index where the output will be sent to

This method will establish an output channel to a layer in a layout. The output sent to that channel will be put into the specified layer and cell. In this version, the layer is specified through a layer index, hence it must be created before.

The name is the name which must be used in the _output function of the scripts in order to address that channel.

(4) Signature: void **output** (string name, Region region)

Description: Specifies output to a Region object

name: The name of the channel

region: The Region object to which the data is sent

This method will establish an output channel to a Region object. The output sent to that channel will be put into the specified region.

The name is the name which must be used in the _output function of the scripts in order to address that channel. Edges sent to this channel are discarded. Edge pairs are converted to polygons.

(5) Signature: void **output** (string name, Edges edges)

Description: Specifies output to an Edges object

name: The name of the channel

edges: The Edges object to which the data is sent

This method will establish an output channel to an Edges object. The output sent to that channel will be put into the specified edge collection. 'Solid' objects such as polygons will be converted to edges by resolving their hulls into edges. Edge pairs are resolved into single edges.

The name is the name which must be used in the _output function of the scripts in order to address that channel.

(6) Signature: void **output** (string name, EdgePairs edge_pairs)

Description: Specifies output to an EdgePairs object

name: The name of the channel

edge_pairs: The EdgePairs object to which the data is sent

This method will establish an output channel to an EdgePairs object. The output sent to that channel will be put into the specified edge pair collection. Only EdgePair objects are accepted. Other objects are discarded.

The name is the name which must be used in the _output function of the scripts in order to address that channel.

(7) Signature: void **output** (string name, Texts texts)

Description: Specifies output to an Texts object

name: The name of the channel

texts: The Texts object to which the data is sent

This method will establish an output channel to an Texts object. The output sent to that channel will be put into the specified edge pair collection. Only Text objects are accepted. Other objects are discarded.

The name is the name which must be used in the _output function of the scripts in order to address that channel.

This variant has been introduced in version 0.27.

(8) Signature: void **output** (string name, double ptr sum)

Description: Specifies output to single value

This method will establish an output channel which sums up float data delivered by calling the _output function. In order to specify the target for the data, a Value object must be provided for the "sum" parameter.

The name is the name which must be used in the _output function of the scripts in order to address that channel.

(9) Signature: void **output** (string name, ReportDatabase rdb, unsigned long cell_id, unsigned long category_id)

Description: Specifies output to a report database

This method will establish an output channel for the processor. The output sent to that channel will be put into the report database given by the "rdb" parameter. "cell_id" specifies the cell and "category_id" the category to use.

The name is the name which must be used in the _output function of the scripts in order to address that channel.

(10) Signature: void **output** (string name, Image ptr image)

Description: Specifies output to an image

This method will establish an output channel which delivers float data to image data. The image is a monochrome image where each pixel corresponds to a single tile. This method for example is useful to collect density information into an image. The image is configured such that each pixel covers one tile.

The name is the name which must be used in the _output function of the scripts in order to address that channel.

queue

Signature: void **queue** (string script)

Description: Queues a script for parallel execution

With this method, scripts are registered that are executed in parallel on each tile. The scripts have "Expressions" syntax and can make use of several predefined variables and functions. See the TilingProcessor class description for details.

scale_to_dbu=

Signature: void **scale_to_dbu=** (bool en)

Description: Enables or disabled automatic scaling to database unit

If automatic scaling to database unit is enabled, the input is automatically scaled to the database unit set inside the tile processor. This is the default.

This method has been introduced in version 0.23.2.

Python specific notes:
The object exposes a writable attribute 'scale_to_dbu'. This is the setter.

scale_to_dbu?

Signature: *[const]* bool **scale_to_dbu?**

Description: Gets a valid indicating whether automatic scaling to database unit is enabled

This method has been introduced in version 0.23.2.

Python specific notes:
The object exposes a readable attribute 'scale_to_dbu'. This is the getter.

threads

Signature: *[const]* unsigned long **threads**

Description: Gets the number of threads to use

Python specific notes:

The object exposes a readable attribute 'threads'. This is the getter.

threads=

Signature: void **threads=** (unsigned long n)

Description: Specifies the number of threads to use

Python specific notes:
The object exposes a writable attribute 'threads'. This is the setter.

tile_border

Signature: void **tile_border** (double bx, double by)

Description: Sets the tile border

Specifies the tile border. The border is a margin that is considered when fetching shapes. By specifying a border you can fetch shapes into the tile's data which are outside the tile but still must be considered in the computations (i.e. because they might grow into the tile).

The tile border is given in micron.

tile_origin

Signature: void **tile_origin** (double xo, double yo)

Description: Sets the tile origin

Specifies the origin (lower left corner) of the tile field. If no origin is specified, the tiles are centered to the layout's bounding box. Giving the origin together with the tile count and dimensions gives full control over the tile array.

The tile origin is given in micron.

tile_size

Signature: void **tile_size** (double w, double h)

Description: Sets the tile size

Specifies the size of the tiles to be used. If no tile size is specified, tiling won't be used and all computations will be done on the whole layout.

The tile size is given in micron.

tiles

Signature: void **tiles** (unsigned long nw, unsigned long nh)

Description: Sets the tile count

Specifies the number of tiles to be used. If no tile number is specified, the number of tiles required is computed from the layout's dimensions and the tile size. If a number is given, but no tile size, the tile size will be computed from the layout's dimensions.

var

Signature: void **var** (string name, variant value)

Description: Defines a variable for the tiling processor script

The name specifies the variable under which the value can be used in the scripts.

4.105. API reference - Class Trans

Notation used in Ruby API documentation

Module: db

Description: A simple transformation

Simple transformations only provide rotations about angles which a multiples of 90 degree. Together with the mirror options, this results in 8 distinct orientations (fixpoint transformations). These can be combined with a displacement which is applied after the rotation/mirror. This version acts on integer coordinates. A version for floating-point coordinates is DTrans.

Here are some examples for using the Trans class:

```
t = RBA::Trans::new(0, 100)  # displacement by 100 DBU in y direction
# the inverse: -> "r0 0,-100"
t.inverted.to_s
# concatenation: -> "r90 -100,0"
(RBA::Trans::R90 * t).to_s
# apply to a point: -> "0,100"
RBA::Trans::R90.trans(RBA::Point::new(100, 0))
```

See The Database API for more details about the database objects.

Public constructors

new Trans ptr	**new**	(const DTrans dtrans)	Creates an integer coordinate transformation from a floating-point coordinate transformation
new Trans ptr	**new**		Creates a unit transformation
new Trans ptr	**new**	(const Trans c, const Vector u = 0,0)	Creates a transformation from another transformation plus a displacement
new Trans ptr	**new**	(const Trans c, int x = 0, int y = 0)	Creates a transformation from another transformation plus a displacement
new Trans ptr	**new**	(int rot = 0, bool mirrx = false, const Vector u = 0,0)	Creates a transformation using angle and mirror flag
new Trans ptr	**new**	(int rot = 0, bool mirrx = false, int x = 0, int y = 0)	Creates a transformation using angle and mirror flag and two coordinate values for displacement
new Trans ptr	**new**	(const Vector u)	Creates a transformation using a displacement only
new Trans ptr	**new**	(int x, int y)	Creates a transformation using a displacement given as two coordinates

Public methods

[const]	bool	**!=**	(const Trans other)	Tests for inequality
[const]	unsigned int	*****	(unsigned int d)	Transforms a distance

[const]	Point	*****	(const Point p)	Transforms a point
[const]	Vector	*****	(const Vector v)	Transforms a vector
[const]	Box	*****	(const Box box)	Transforms a box
[const]	Edge	*****	(const Edge edge)	Transforms an edge
[const]	Polygon	*****	(const Polygon polygon)	Transforms a polygon
[const]	Path	*****	(const Path path)	Transforms a path
[const]	Text	*****	(const Text text)	Transforms a text
[const]	Trans	*****	(const Trans t)	Returns the concatenated transformation
[const]	bool	**<**	(const Trans other)	Provides a 'less' criterion for sorting
[const]	bool	**==**	(const Trans other)	Tests for equality
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	int	**angle**		Gets the angle in units of 90 degree
	void	**angle=**	(int a)	Sets the angle in units of 90 degree
	void	**assign**	(const Trans other)	Assigns another object to self
[const]	unsigned int	**ctrans**	(unsigned int d)	Transforms a distance
[const]	Vector	**disp**		Gets to the displacement vector
	void	**disp=**	(const Vector u)	Sets the displacement
[const]	new Trans ptr	**dup**		Creates a copy of self
[const]	unsigned long	**hash**		Computes a hash value
	Trans	**invert**		Inverts the transformation (in place)
[const]	Trans	**inverted**		Returns the inverted transformation
[const]	bool	**is_mirror?**		Gets the mirror flag

	void	**mirror=**	(bool m)	Sets the mirror flag
[const]	int	**rot**		Gets the angle/mirror code
	void	**rot=**	(int r)	Sets the angle/mirror code
[const]	DTrans	**to_dtype**	(double dbu = 1)	Converts the transformation to a floating-point coordinate transformation
[const]	string	**to_s**	(double dbu = 0)	String conversion
[const]	Point	**trans**	(const Point p)	Transforms a point
[const]	Vector	**trans**	(const Vector v)	Transforms a vector
[const]	Box	**trans**	(const Box box)	Transforms a box
[const]	Edge	**trans**	(const Edge edge)	Transforms an edge
[const]	Polygon	**trans**	(const Polygon polygon)	Transforms a polygon
[const]	Path	**trans**	(const Path path)	Transforms a path
[const]	Text	**trans**	(const Text text)	Transforms a text

Public static methods and constants

Trans	**M0**		A constant giving "mirrored at the x-axis" transformation
Trans	**M135**		A constant giving "mirrored at the 135 degree axis" transformation
Trans	**M45**		A constant giving "mirrored at the 45 degree axis" transformation
Trans	**M90**		A constant giving "mirrored at the y (90 degree) axis" transformation
Trans	**R0**		A constant giving "unrotated" (unit) transformation
Trans	**R180**		A constant giving "rotated by 180 degree counterclockwise" transformation
Trans	**R270**		A constant giving "rotated by 270 degree counterclockwise" transformation
Trans	**R90**		A constant giving "rotated by 90 degree counterclockwise" transformation
new Trans ptr	**from_s**	(string s)	Creates a transformation from a string

Deprecated methods (protected, public, static, non-static and constructors)

void	**create**		Use of this method is deprecated. Use _create instead

	void	**destroy**		Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**		Use of this method is deprecated. Use _destroyed? instead
[static]	new Trans ptr	**from_dtrans**	(const DTrans dtrans)	Use of this method is deprecated. Use new instead
[const]	bool	**is_const_object?**		Use of this method is deprecated. Use _is_const_object? instead

Detailed description

!=

Signature: *[const]* bool **!=** (const Trans other)

Description: Tests for inequality

*****

(1) Signature: *[const]* unsigned int ***** (unsigned int d)

Description: Transforms a distance

d: The distance to transform

Returns: The transformed distance

The "ctrans" method transforms the given distance. e = t(d). For the simple transformations, there is no magnification and no modification of the distance therefore.

The product '*' has been added as a synonym in version 0.28.

Python specific notes:
This method also implements '__rmul__'.

(2) Signature: *[const]* Point ***** (const Point p)

Description: Transforms a point

p: The point to transform

Returns: The transformed point

The "trans" method or the * operator transforms the given point. q = t(p)

The * operator has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(3) Signature: *[const]* Vector ***** (const Vector v)

Description: Transforms a vector

v: The vector to transform

Returns: The transformed vector

The "trans" method or the * operator transforms the given vector. w = t(v)

Vector transformation has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(4) Signature: *[const]* Box ***** (const Box box)

Description: Transforms a box

box:	The box to transform
Returns:	The transformed box

't*box' or 't.trans(box)' is equivalent to box.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(5) Signature: *[const]* Edge ***** (const Edge edge)

Description: Transforms an edge

edge:	The edge to transform
Returns:	The transformed edge

't*edge' or 't.trans(edge)' is equivalent to edge.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(6) Signature: *[const]* Polygon ***** (const Polygon polygon)

Description: Transforms a polygon

polygon:	The polygon to transform
Returns:	The transformed polygon

't*polygon' or 't.trans(polygon)' is equivalent to polygon.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(7) Signature: *[const]* Path ***** (const Path path)

Description: Transforms a path

path:	The path to transform
Returns:	The transformed path

't*path' or 't.trans(path)' is equivalent to path.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(8) Signature: *[const]* Text ***** (const Text text)

Description: Transforms a text

text:	The text to transform
Returns:	The transformed text

't*text' or 't.trans(text)' is equivalent to text.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(9) Signature: *[const]* Trans ***** (const Trans t)

Description: Returns the concatenated transformation

t:	The transformation to apply before
Returns:	The modified transformation

The * operator returns self*t ("t is applied before this transformation").

<

Signature: *[const]* bool **<** (const Trans other)

Description: Provides a 'less' criterion for sorting

This method is provided to implement a sorting order. The definition of 'less' is opaque and might change in future versions.

==

Signature: *[const]* bool **==** (const Trans other)

Description: Tests for equality

M0

Signature: *[static]* Trans **M0**

Description: A constant giving "mirrored at the x-axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M0'. This is the getter.

M135

Signature: *[static]* Trans **M135**

Description: A constant giving "mirrored at the 135 degree axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M135'. This is the getter.

M45

Signature: *[static]* Trans **M45**

Description: A constant giving "mirrored at the 45 degree axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M45'. This is the getter.

M90

Signature: *[static]* Trans **M90**

Description: A constant giving "mirrored at the y (90 degree) axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M90'. This is the getter.

R0

Signature: *[static]* Trans **R0**

Description: A constant giving "unrotated" (unit) transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R0'. This is the getter.

R180

Signature: *[static]* Trans **R180**

Description: A constant giving "rotated by 180 degree counterclockwise" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R180'. This is the getter.

R270

Signature: *[static]* Trans **R270**

Description: A constant giving "rotated by 270 degree counterclockwise" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R270'. This is the getter.

R90

Signature: *[static]* Trans **R90**

Description: A constant giving "rotated by 90 degree counterclockwise" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R90'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

angle

Signature: *[const]* int **angle**

Description: Gets the angle in units of 90 degree

This value delivers the rotation component. In addition, a mirroring at the x axis may be applied before if the is_mirror? property is true.

Python specific notes:
The object exposes a readable attribute 'angle'. This is the getter.

angle=

Signature: void **angle=** (int a)

Description: Sets the angle in units of 90 degree

a:	The new angle

This method was introduced in version 0.20.

Python specific notes:
The object exposes a writable attribute 'angle'. This is the setter.

assign

Signature: void **assign** (const Trans other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

ctrans

Signature: *[const]* unsigned int **ctrans** (unsigned int d)

Description: Transforms a distance

d:	The distance to transform
Returns:	The transformed distance

The "ctrans" method transforms the given distance. e = t(d). For the simple transformations, there is no magnification and no modification of the distance therefore.

The product '*' has been added as a synonym in version 0.28.

Python specific notes:
This method also implements '__rmul__'.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

disp

Signature: *[const]* Vector **disp**

Description: Gets to the displacement vector

Staring with version 0.25 the displacement type is a vector.

Python specific notes:
The object exposes a readable attribute 'disp'. This is the getter.

disp=

Signature: void **disp=** (const Vector u)

Description: Sets the displacement

u: The new displacement

This method was introduced in version 0.20. Staring with version 0.25 the displacement type is a vector.

Python specific notes:
The object exposes a writable attribute 'disp'. This is the setter.

dup

Signature: *[const]* new Trans ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

from_dtrans

Signature: *[static]* new Trans ptr **from_dtrans** (const DTrans dtrans)

Description: Creates an integer coordinate transformation from a floating-point coordinate transformation

Use of this method is deprecated. Use new instead

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_dtrans'.

Python specific notes:
This method is the default initializer of the object.

from_s

Signature: *[static]* new Trans ptr **from_s** (string s)

Description: Creates a transformation from a string

Creates the object from a string representation (as returned by to_s)

This method has been added in version 0.23.

hash

Signature: *[const]* unsigned long **hash**

Description: Computes a hash value

Returns a hash value for the given transformation. This method enables transformations as hash keys.

This method has been introduced in version 0.25.

Python specific notes:
This method is also available as 'hash(object)'.

invert

Signature: Trans **invert**

Description: Inverts the transformation (in place)

Returns: The inverted transformation

Inverts the transformation and replaces this object by the inverted one.

inverted

Signature: *[const]* Trans **inverted**

Description: Returns the inverted transformation

Returns: The inverted transformation

Returns the inverted transformation

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_mirror?

Signature: *[const]* bool **is_mirror?**

Description: Gets the mirror flag

If this property is true, the transformation is composed of a mirroring at the x-axis followed by a rotation by the angle given by the angle property.

Python specific notes:
The object exposes a readable attribute 'mirror'. This is the getter.

mirror=

Signature: void **mirror=** (bool m)

Description: Sets the mirror flag

m: The new mirror flag

"mirroring" describes a reflection at the x-axis which is included in the transformation prior to rotation.

This method was introduced in version 0.20.

Python specific notes:
The object exposes a writable attribute 'mirror'. This is the setter.

new

(1) Signature: *[static]* new Trans ptr **new** (const DTrans dtrans)

Description: Creates an integer coordinate transformation from a floating-point coordinate transformation

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_dtrans'.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new Trans ptr **new**

Description: Creates a unit transformation

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new Trans ptr **new** (const Trans c, const Vector u = 0,0)

Description: Creates a transformation from another transformation plus a displacement

c:	The original transformation
u:	The Additional displacement

Creates a new transformation from a existing transformation. This constructor is provided for creating duplicates and backward compatibility since the constants are transformations now. It will copy the original transformation and add the given displacement.

This variant has been introduced in version 0.25.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new Trans ptr **new** (const Trans c, int x = 0, int y = 0)

Description: Creates a transformation from another transformation plus a displacement

c:	The original transformation
x:	The Additional displacement (x)
y:	The Additional displacement (y)

Creates a new transformation from a existing transformation. This constructor is provided for creating duplicates and backward compatibility since the constants are transformations now. It will copy the original transformation and add the given displacement.

This variant has been introduced in version 0.25.

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new Trans ptr **new** (int rot = 0, bool mirrx = false, const Vector u = 0,0)

Description: Creates a transformation using angle and mirror flag

rot:	The rotation in units of 90 degree
mirrx:	True, if mirrored at x axis
u:	The displacement

The sequence of operations is: mirroring at x axis, rotation, application of displacement.

Python specific notes:
This method is the default initializer of the object.

(6) Signature: *[static]* new Trans ptr **new** (int rot = 0, bool mirrx = false, int x = 0, int y = 0)

Description: Creates a transformation using angle and mirror flag and two coordinate values for displacement

rot:	The rotation in units of 90 degree
mirrx:	True, if mirrored at x axis
x:	The horizontal displacement
y:	The vertical displacement

The sequence of operations is: mirroring at x axis, rotation, application of displacement.

Python specific notes:

This method is the default initializer of the object.

(7) Signature: *[static]* new Trans ptr **new** (const Vector u)

Description: Creates a transformation using a displacement only

u: The displacement

Python specific notes:
This method is the default initializer of the object.

(8) Signature: *[static]* new Trans ptr **new** (int x, int y)

Description: Creates a transformation using a displacement given as two coordinates

x: The horizontal displacement

y: The vertical displacement

Python specific notes:
This method is the default initializer of the object.

rot

Signature: *[const]* int **rot**

Description: Gets the angle/mirror code

The angle/mirror code is one of the constants R0, R90, R180, R270, M0, M45, M90 and M135. rx is the rotation by an angle of x counter clockwise. mx is the mirroring at the axis given by the angle x (to the x-axis).

Python specific notes:
The object exposes a readable attribute 'rot'. This is the getter.

rot=

Signature: void **rot=** (int r)

Description: Sets the angle/mirror code

r: The new angle/rotation code (see rot property)

This method was introduced in version 0.20.

Python specific notes:
The object exposes a writable attribute 'rot'. This is the setter.

to_dtype

Signature: *[const]* DTrans **to_dtype** (double dbu = 1)

Description: Converts the transformation to a floating-point coordinate transformation

The database unit can be specified to translate the integer-coordinate transformation into a floating-point coordinate transformation in micron units. The database unit is basically a scaling factor.

This method has been introduced in version 0.25.

to_s

Signature: *[const]* string **to_s** (double dbu = 0)

Description: String conversion

If a DBU is given, the output units will be micrometers.

The DBU argument has been added in version 0.27.6.

Python specific notes:
This method is also available as 'str(object)'.

trans

(1) Signature: *[const]* Point **trans** (const Point p)

Description: Transforms a point

p:	The point to transform
Returns:	The transformed point

The "trans" method or the * operator transforms the given point. q = t(p)

The * operator has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(2) Signature: *[const]* Vector **trans** (const Vector v)

Description: Transforms a vector

v:	The vector to transform
Returns:	The transformed vector

The "trans" method or the * operator transforms the given vector. w = t(v)

Vector transformation has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(3) Signature: *[const]* Box **trans** (const Box box)

Description: Transforms a box

box:	The box to transform
Returns:	The transformed box

't*box' or 't.trans(box)' is equivalent to box.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(4) Signature: *[const]* Edge **trans** (const Edge edge)

Description: Transforms an edge

edge:	The edge to transform
Returns:	The transformed edge

't*edge' or 't.trans(edge)' is equivalent to edge.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(5) Signature: *[const]* Polygon **trans** (const Polygon polygon)

Description: Transforms a polygon

polygon:	The polygon to transform
Returns:	The transformed polygon

't*polygon' or 't.trans(polygon)' is equivalent to polygon.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(6) Signature: *[const]* Path **trans** (const Path path)

Description: Transforms a path

path:	The path to transform
Returns:	The transformed path

't*path' or 't.trans(path)' is equivalent to path.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(7) Signature: *[const]* Text **trans** (const Text text)

Description: Transforms a text

text:	The text to transform
Returns:	The transformed text

't*text' or 't.trans(text)' is equivalent to text.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

4.106. API reference - Class DTrans

Notation used in Ruby API documentation

Module: db

Description: A simple transformation

Simple transformations only provide rotations about angles which a multiples of 90 degree. Together with the mirror options, this results in 8 distinct orientations (fixpoint transformations). These can be combined with a displacement which is applied after the rotation/mirror. This version acts on floating-point coordinates. A version for integer coordinates is Trans.

Here are some examples for using the DTrans class:

```
t = RBA::DTrans::new(0, 100)  # displacement by 100 DBU in y direction
# the inverse: -> "r0 0,-100"
t.inverted.to_s
# concatenation: -> "r90 -100,0"
(RBA::DTrans::new(RBA::DTrans::R90) * t).to_s
# apply to a point: -> "0,100"
RBA::DTrans::new(RBA::DTrans::R90).trans(RBA::DPoint::new(100, 0))
```

See The Database API for more details about the database objects.

Public constructors

new DTrans ptr	**new**	(const Trans trans)	Creates a floating-point coordinate transformation from an integer coordinate transformation
new DTrans ptr	**new**		Creates a unit transformation
new DTrans ptr	**new**	(const DTrans c, const DVector u = 0,0)	Creates a transformation from another transformation plus a displacement
new DTrans ptr	**new**	(const DTrans c, double x = 0, double y = 0)	Creates a transformation from another transformation plus a displacement
new DTrans ptr	**new**	(int rot = 0, bool mirrx = false, const DVector u = 0,0)	Creates a transformation using angle and mirror flag
new DTrans ptr	**new**	(int rot = 0, bool mirrx = false, double x = 0, double y = 0)	Creates a transformation using angle and mirror flag and two coordinate values for displacement
new DTrans ptr	**new**	(const DVector u)	Creates a transformation using a displacement only
new DTrans ptr	**new**	(double x, double y)	Creates a transformation using a displacement given as two coordinates

Public methods

[const]	bool	**!=**	(const DTrans other)	Tests for inequality

[const]	double	*	(double d)	Transforms a distance
[const]	DPoint	*	(const DPoint p)	Transforms a point
[const]	DVector	*	(const DVector v)	Transforms a vector
[const]	DBox	*	(const DBox box)	Transforms a box
[const]	DEdge	*	(const DEdge edge)	Transforms an edge
[const]	DPolygon	*	(const DPolygon polygon)	Transforms a polygon
[const]	DPath	*	(const DPath path)	Transforms a path
[const]	DText	*	(const DText text)	Transforms a text
[const]	DTrans	*	(const DTrans t)	Returns the concatenated transformation
[const]	bool	<	(const DTrans other)	Provides a 'less' criterion for sorting
[const]	bool	==	(const DTrans other)	Tests for equality
	void	_create		Ensures the C++ object is created
	void	_destroy		Explicitly destroys the object
[const]	bool	_destroyed?		Returns a value indicating whether the object was already destroyed
[const]	bool	_is_const_object?		Returns a value indicating whether the reference is a const reference
	void	_manage		Marks the object as managed by the script side.
	void	_unmanage		Marks the object as no longer owned by the script side.
[const]	int	angle		Gets the angle in units of 90 degree
	void	angle=	(int a)	Sets the angle in units of 90 degree
	void	assign	(const DTrans other)	Assigns another object to self
[const]	double	ctrans	(double d)	Transforms a distance
[const]	DVector	disp		Gets to the displacement vector
	void	disp=	(const DVector u)	Sets the displacement
[const]	new DTrans ptr	dup		Creates a copy of self
[const]	unsigned long	hash		Computes a hash value
	DTrans	invert		Inverts the transformation (in place)
[const]	DTrans	inverted		Returns the inverted transformation

[const]	bool	**is_mirror?**		Gets the mirror flag
	void	**mirror=**	(bool m)	Sets the mirror flag
[const]	int	**rot**		Gets the angle/mirror code
	void	**rot=**	(int r)	Sets the angle/mirror code
[const]	Trans	**to_itype**	(double dbu = 1)	Converts the transformation to an integer coordinate transformation
[const]	string	**to_s**	(double dbu = 0)	String conversion
[const]	DPoint	**trans**	(const DPoint p)	Transforms a point
[const]	DVector	**trans**	(const DVector v)	Transforms a vector
[const]	DBox	**trans**	(const DBox box)	Transforms a box
[const]	DEdge	**trans**	(const DEdge edge)	Transforms an edge
[const]	DPolygon	**trans**	(const DPolygon polygon)	Transforms a polygon
[const]	DPath	**trans**	(const DPath path)	Transforms a path
[const]	DText	**trans**	(const DText text)	Transforms a text

Public static methods and constants

DTrans	**M0**		A constant giving "mirrored at the x-axis" transformation
DTrans	**M135**		A constant giving "mirrored at the 135 degree axis" transformation
DTrans	**M45**		A constant giving "mirrored at the 45 degree axis" transformation
DTrans	**M90**		A constant giving "mirrored at the y (90 degree) axis" transformation
DTrans	**R0**		A constant giving "unrotated" (unit) transformation
DTrans	**R180**		A constant giving "rotated by 180 degree counterclockwise" transformation
DTrans	**R270**		A constant giving "rotated by 270 degree counterclockwise" transformation
DTrans	**R90**		A constant giving "rotated by 90 degree counterclockwise" transformation
new DTrans ptr	**from_s**	(string s)	Creates a transformation from a string

Deprecated methods (protected, public, static, non-static and constructors)

void	**create**		Use of this method is deprecated. Use _create instead

	void	**destroy**		Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**		Use of this method is deprecated. Use _destroyed? instead
[static]	new DTrans ptr	**from_itrans**	(const Trans trans)	Use of this method is deprecated. Use new instead
[const]	bool	**is_const_object?**		Use of this method is deprecated. Use _is_const_object? instead

Detailed description

!=

Signature: *[const]* bool **!=** (const DTrans other)

Description: Tests for inequality

*****

(1) Signature: *[const]* double ***** (double d)

Description: Transforms a distance

d: The distance to transform

Returns: The transformed distance

The "ctrans" method transforms the given distance. e = t(d). For the simple transformations, there is no magnification and no modification of the distance therefore.

The product '*' has been added as a synonym in version 0.28.

Python specific notes:
This method also implements '__rmul__'.

(2) Signature: *[const]* DPoint ***** (const DPoint p)

Description: Transforms a point

p: The point to transform

Returns: The transformed point

The "trans" method or the * operator transforms the given point. q = t(p)

The * operator has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(3) Signature: *[const]* DVector ***** (const DVector v)

Description: Transforms a vector

v: The vector to transform

Returns: The transformed vector

The "trans" method or the * operator transforms the given vector. w = t(v)

Vector transformation has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(4) Signature: *[const]* DBox ***** (const DBox box)

Description: Transforms a box

box:	The box to transform
Returns:	The transformed box

't*box' or 't.trans(box)' is equivalent to box.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(5) Signature: *[const]* DEdge ***** (const DEdge edge)

Description: Transforms an edge

edge:	The edge to transform
Returns:	The transformed edge

't*edge' or 't.trans(edge)' is equivalent to edge.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(6) Signature: *[const]* DPolygon ***** (const DPolygon polygon)

Description: Transforms a polygon

polygon:	The polygon to transform
Returns:	The transformed polygon

't*polygon' or 't.trans(polygon)' is equivalent to polygon.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(7) Signature: *[const]* DPath ***** (const DPath path)

Description: Transforms a path

path:	The path to transform
Returns:	The transformed path

't*path' or 't.trans(path)' is equivalent to path.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(8) Signature: *[const]* DText ***** (const DText text)

Description: Transforms a text

text:	The text to transform
Returns:	The transformed text

't*text' or 't.trans(text)' is equivalent to text.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(9) Signature: *[const]* DTrans ***** (const DTrans t)

Description: Returns the concatenated transformation

t:	The transformation to apply before
Returns:	The modified transformation

The * operator returns self*t ("t is applied before this transformation").

<

Signature: *[const]* bool **<** (const DTrans other)

Description: Provides a 'less' criterion for sorting

This method is provided to implement a sorting order. The definition of 'less' is opaque and might change in future versions.

==

Signature: *[const]* bool **==** (const DTrans other)

Description: Tests for equality

M0

Signature: *[static]* DTrans **M0**

Description: A constant giving "mirrored at the x-axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M0'. This is the getter.

M135

Signature: *[static]* DTrans **M135**

Description: A constant giving "mirrored at the 135 degree axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M135'. This is the getter.

M45

Signature: *[static]* DTrans **M45**

Description: A constant giving "mirrored at the 45 degree axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M45'. This is the getter.

M90

Signature: *[static]* DTrans **M90**

Description: A constant giving "mirrored at the y (90 degree) axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M90'. This is the getter.

R0

Signature: *[static]* DTrans **R0**

Description: A constant giving "unrotated" (unit) transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R0'. This is the getter.

R180

Signature: *[static]* DTrans **R180**

Description: A constant giving "rotated by 180 degree counterclockwise" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R180'. This is the getter.

R270

Signature: *[static]* DTrans **R270**

Description: A constant giving "rotated by 270 degree counterclockwise" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R270'. This is the getter.

R90

Signature: *[static]* DTrans **R90**

Description: A constant giving "rotated by 90 degree counterclockwise" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R90'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

angle

Signature: *[const]* int **angle**

Description: Gets the angle in units of 90 degree

This value delivers the rotation component. In addition, a mirroring at the x axis may be applied before if the is_mirror? property is true.

Python specific notes:
The object exposes a readable attribute 'angle'. This is the getter.

angle=

Signature: void **angle=** (int a)

Description: Sets the angle in units of 90 degree

a:	The new angle

This method was introduced in version 0.20.

Python specific notes:
The object exposes a writable attribute 'angle'. This is the setter.

assign

Signature: void **assign** (const DTrans other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

ctrans

Signature: *[const]* double **ctrans** (double d)

Description: Transforms a distance

d:	The distance to transform
Returns:	The transformed distance

The "ctrans" method transforms the given distance. e = t(d). For the simple transformations, there is no magnification and no modification of the distance therefore.

The product '*' has been added as a synonym in version 0.28.

Python specific notes:
This method also implements '__rmul__'.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

disp

Signature: *[const]* DVector **disp**

Description: Gets to the displacement vector

Staring with version 0.25 the displacement type is a vector.

Python specific notes:
The object exposes a readable attribute 'disp'. This is the getter.

disp=

Signature: void **disp=** (const DVector u)

Description: Sets the displacement

u: The new displacement

This method was introduced in version 0.20. Staring with version 0.25 the displacement type is a vector.

Python specific notes:
The object exposes a writable attribute 'disp'. This is the setter.

dup

Signature: *[const]* new DTrans ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

from_itrans

Signature: *[static]* new DTrans ptr **from_itrans** (const Trans trans)

Description: Creates a floating-point coordinate transformation from an integer coordinate transformation

Use of this method is deprecated. Use new instead

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_itrans'.

Python specific notes:
This method is the default initializer of the object.

from_s

Signature: *[static]* new DTrans ptr **from_s** (string s)

Description: Creates a transformation from a string

Creates the object from a string representation (as returned by to_s)

This method has been added in version 0.23.

hash

Signature: *[const]* unsigned long **hash**

Description: Computes a hash value

Returns a hash value for the given transformation. This method enables transformations as hash keys.

This method has been introduced in version 0.25.

Python specific notes:
This method is also available as 'hash(object)'.

invert

Signature: DTrans **invert**

Description: Inverts the transformation (in place)

Returns: The inverted transformation

Inverts the transformation and replaces this object by the inverted one.

inverted

Signature: *[const]* DTrans **inverted**

Description: Returns the inverted transformation

Returns: The inverted transformation

Returns the inverted transformation

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_mirror?

Signature: *[const]* bool **is_mirror?**

Description: Gets the mirror flag

If this property is true, the transformation is composed of a mirroring at the x-axis followed by a rotation by the angle given by the angle property.

Python specific notes:
The object exposes a readable attribute 'mirror'. This is the getter.

mirror=

Signature: void **mirror=** (bool m)

Description: Sets the mirror flag

m: The new mirror flag

"mirroring" describes a reflection at the x-axis which is included in the transformation prior to rotation.

This method was introduced in version 0.20.

Python specific notes:
The object exposes a writable attribute 'mirror'. This is the setter.

new

(1) Signature: *[static]* new DTrans ptr **new** (const Trans trans)

Description: Creates a floating-point coordinate transformation from an integer coordinate transformation

This constructor has been introduced in version 0.25 and replaces the previous static method 'from_itrans'.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new DTrans ptr **new**

Description: Creates a unit transformation

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new DTrans ptr **new** (const DTrans c, const DVector u = 0,0)

Description: Creates a transformation from another transformation plus a displacement

c:	The original transformation
u:	The Additional displacement

Creates a new transformation from a existing transformation. This constructor is provided for creating duplicates and backward compatibility since the constants are transformations now. It will copy the original transformation and add the given displacement.

This variant has been introduced in version 0.25.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new DTrans ptr **new** (const DTrans c, double x = 0, double y = 0)

Description: Creates a transformation from another transformation plus a displacement

c:	The original transformation
x:	The Additional displacement (x)
y:	The Additional displacement (y)

Creates a new transformation from a existing transformation. This constructor is provided for creating duplicates and backward compatibility since the constants are transformations now. It will copy the original transformation and add the given displacement.

This variant has been introduced in version 0.25.

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new DTrans ptr **new** (int rot = 0, bool mirrx = false, const DVector u = 0,0)

Description: Creates a transformation using angle and mirror flag

rot:	The rotation in units of 90 degree
mirrx:	True, if mirrored at x axis
u:	The displacement

The sequence of operations is: mirroring at x axis, rotation, application of displacement.

Python specific notes:
This method is the default initializer of the object.

(6) Signature: *[static]* new DTrans ptr **new** (int rot = 0, bool mirrx = false, double x = 0, double y = 0)

Description: Creates a transformation using angle and mirror flag and two coordinate values for displacement

rot:	The rotation in units of 90 degree
mirrx:	True, if mirrored at x axis
x:	The horizontal displacement
y:	The vertical displacement

The sequence of operations is: mirroring at x axis, rotation, application of displacement.

Python specific notes:

This method is the default initializer of the object.

(7) Signature: *[static]* new DTrans ptr **new** (const DVector u)

Description: Creates a transformation using a displacement only

u: The displacement

Python specific notes:
This method is the default initializer of the object.

(8) Signature: *[static]* new DTrans ptr **new** (double x, double y)

Description: Creates a transformation using a displacement given as two coordinates

x: The horizontal displacement

y: The vertical displacement

Python specific notes:
This method is the default initializer of the object.

rot

Signature: *[const]* int **rot**

Description: Gets the angle/mirror code

The angle/mirror code is one of the constants R0, R90, R180, R270, M0, M45, M90 and M135. rx is the rotation by an angle of x counter clockwise. mx is the mirroring at the axis given by the angle x (to the x-axis).

Python specific notes:
The object exposes a readable attribute 'rot'. This is the getter.

rot=

Signature: void **rot=** (int r)

Description: Sets the angle/mirror code

r: The new angle/rotation code (see rot property)

This method was introduced in version 0.20.

Python specific notes:
The object exposes a writable attribute 'rot'. This is the setter.

to_itype

Signature: *[const]* Trans **to_itype** (double dbu = 1)

Description: Converts the transformation to an integer coordinate transformation

The database unit can be specified to translate the floating-point coordinate transformation in micron units to an integer-coordinate transformation in database units. The transformation's' coordinates will be divided by the database unit.

This method has been introduced in version 0.25.

to_s

Signature: *[const]* string **to_s** (double dbu = 0)

Description: String conversion

If a DBU is given, the output units will be micrometers.

The DBU argument has been added in version 0.27.6.

Python specific notes:
This method is also available as 'str(object)'.

trans

(1) Signature: *[const]* DPoint **trans** (const DPoint p)

Description: Transforms a point

p:	The point to transform
Returns:	The transformed point

The "trans" method or the * operator transforms the given point. q = t(p)

The * operator has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(2) Signature: *[const]* DVector **trans** (const DVector v)

Description: Transforms a vector

v:	The vector to transform
Returns:	The transformed vector

The "trans" method or the * operator transforms the given vector. w = t(v)

Vector transformation has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(3) Signature: *[const]* DBox **trans** (const DBox box)

Description: Transforms a box

box:	The box to transform
Returns:	The transformed box

't*box' or 't.trans(box)' is equivalent to box.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(4) Signature: *[const]* DEdge **trans** (const DEdge edge)

Description: Transforms an edge

edge:	The edge to transform
Returns:	The transformed edge

't*edge' or 't.trans(edge)' is equivalent to edge.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(5) Signature: *[const]* DPolygon **trans** (const DPolygon polygon)

Description: Transforms a polygon

polygon:	The polygon to transform
Returns:	The transformed polygon

't*polygon' or 't.trans(polygon)' is equivalent to polygon.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:

This method also implements '__rmul__'.

(6) Signature: *[const]* DPath **trans** (const DPath path)

Description: Transforms a path

path:	The path to transform
Returns:	The transformed path

't*path' or 't.trans(path)' is equivalent to path.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(7) Signature: *[const]* DText **trans** (const DText text)

Description: Transforms a text

text:	The text to transform
Returns:	The transformed text

't*text' or 't.trans(text)' is equivalent to text.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

4.107. API reference - Class DCplxTrans

Notation used in Ruby API documentation

Module: db

Description: A complex transformation

A complex transformation provides magnification, mirroring at the x-axis, rotation by an arbitrary angle and a displacement. This is also the order, the operations are applied.

A complex transformation provides a superset of the simple transformation. In many applications, a complex transformation computes floating-point coordinates to minimize rounding effects. This version can transform floating-point coordinate objects.

Complex transformations are extensions of the simple transformation classes (DTrans in that case) and behave similar.

Transformations can be used to transform points or other objects. Transformations can be combined with the '*' operator to form the transformation which is equivalent to applying the second and then the first. Here is some code:

```
# Create a transformation that applies a magnification of 1.5, a rotation by 90 degree
# and displacement of 10 in x and 20 units in y direction:
t = RBA::CplxTrans::new(1.5, 90, false, 10.0, 20.0)
t.to_s            # r90 *1.5 10,20
# compute the inverse:
t.inverted.to_s   # r270 *0.666666667 -13,7
# Combine with another displacement (applied after that):
(RBA::CplxTrans::new(5, 5) * t).to_s    # r90 *1.5 15,25
# Transform a point:
t.trans(RBA::Point::new(100, 200)).to_s # -290,170
```

See The Database API for more details about the database objects.

Public constructors

new DCplxTrans ptr	**new**	(const CplxTrans trans, double dbu = 1)	Creates a floating-point coordinate transformation from another coordinate flavour
new DCplxTrans ptr	**new**	(const ICplxTrans trans, double dbu = 1)	Creates a floating-point coordinate transformation from another coordinate flavour
new DCplxTrans ptr	**new**	(const VCplxTrans trans, double dbu = 1)	Creates a floating-point coordinate transformation from another coordinate flavour
new DCplxTrans ptr	**new**		Creates a unit transformation
new DCplxTrans ptr	**new**	(const DCplxTrans c, double mag = 1, const DVector u = 0,0)	Creates a transformation from another transformation plus a magnification and displacement
new DCplxTrans ptr	**new**	(const DCplxTrans c, double mag = 1, double x = 0, double y = 0)	Creates a transformation from another transformation plus a magnification and displacement
new DCplxTrans ptr	**new**	(double x, double y)	Creates a transformation from a x and y displacement
new DCplxTrans ptr	**new**	(const DTrans t, double mag = 1)	Creates a transformation from a simple transformation and a magnification

new DCplxTrans ptr	new	(const DVector u)	Creates a transformation from a displacement
new DCplxTrans ptr	new	(double mag = 1, double rot = 0, bool mirrx = false, const DVector u = 0,0)	Creates a transformation using magnification, angle, mirror flag and displacement
new DCplxTrans ptr	new	(double mag = 1, double rot = 0, bool mirrx = false, double x = 0, double y = 0)	Creates a transformation using magnification, angle, mirror flag and displacement

Public methods

[const]	bool	!=	(const DCplxTrans other)	Tests for inequality
[const]	CplxTrans	*	(const CplxTrans t)	Multiplication (concatenation) of transformations
[const]	double	*	(double d)	Transforms a distance
[const]	DPoint	*	(const DPoint p)	Transforms a point
[const]	DVector	*	(const DVector p)	Transforms a vector
[const]	DBox	*	(const DBox box)	Transforms a box
[const]	DEdge	*	(const DEdge edge)	Transforms an edge
[const]	DPolygon	*	(const DPolygon polygon)	Transforms a polygon
[const]	DPath	*	(const DPath path)	Transforms a path
[const]	DText	*	(const DText text)	Transforms a text
[const]	DCplxTrans	*	(const DCplxTrans t)	Returns the concatenated transformation
[const]	bool	<	(const DCplxTrans other)	Provides a 'less' criterion for sorting
[const]	bool	==	(const DCplxTrans other)	Tests for equality
	void	_create		Ensures the C++ object is created
	void	_destroy		Explicitly destroys the object
[const]	bool	_destroyed?		Returns a value indicating whether the object was already destroyed
[const]	bool	_is_const_object?		Returns a value indicating whether the reference is a const reference

	void	_manage		Marks the object as managed by the script side.
	void	_unmanage		Marks the object as no longer owned by the script side.
[const]	double	angle		Gets the angle
	void	angle=	(double a)	Sets the angle
	void	assign	(const DCplxTrans other)	Assigns another object to self
[const]	double	ctrans	(double d)	Transforms a distance
[const]	DVector	disp		Gets the displacement
	void	disp=	(const DVector u)	Sets the displacement
[const]	new DCplxTrans ptr	dup		Creates a copy of self
[const]	unsigned long	hash		Computes a hash value
	DCplxTrans	invert		Inverts the transformation (in place)
[const]	DCplxTrans	inverted		Returns the inverted transformation
[const]	bool	is_complex?		Returns true if the transformation is a complex one
[const]	bool	is_mag?		Tests, if the transformation is a magnifying one
[const]	bool	is_mirror?		Gets the mirror flag
[const]	bool	is_ortho?		Tests, if the transformation is an orthogonal transformation
[const]	bool	is_unity?		Tests, whether this is a unit transformation
[const]	double	mag		Gets the magnification
	void	mag=	(double m)	Sets the magnification
	void	mirror=	(bool m)	Sets the mirror flag
[const]	int	rot		Returns the respective simple transformation equivalent rotation code if possible
[const]	DTrans	s_trans		Extracts the simple transformation part
[const]	string	to_s	(bool lazy = false, double dbu = 0)	String conversion
[const]	DPoint	trans	(const DPoint p)	Transforms a point

[const]	DVector	**trans**	(const DVector p)	Transforms a vector
[const]	DBox	**trans**	(const DBox box)	Transforms a box
[const]	DEdge	**trans**	(const DEdge edge)	Transforms an edge
[const]	DPolygon	**trans**	(const DPolygon polygon)	Transforms a polygon
[const]	DPath	**trans**	(const DPath path)	Transforms a path
[const]	DText	**trans**	(const DText text)	Transforms a text

Public static methods and constants

	DCplxTrans	**M0**		A constant giving "mirrored at the x-axis" transformation
	DCplxTrans	**M135**		A constant giving "mirrored at the 135 degree axis" transformation
	DCplxTrans	**M45**		A constant giving "mirrored at the 45 degree axis" transformation
	DCplxTrans	**M90**		A constant giving "mirrored at the y (90 degree) axis" transformation
	DCplxTrans	**R0**		A constant giving "unrotated" (unit) transformation
	DCplxTrans	**R180**		A constant giving "rotated by 180 degree counterclockwise" transformation
	DCplxTrans	**R270**		A constant giving "rotated by 270 degree counterclockwise" transformation
	DCplxTrans	**R90**		A constant giving "rotated by 90 degree counterclockwise" transformation
	new DCplxTrans ptr	**from_s**	(string s)	Creates an object from a string

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**		Use of this method is deprecated. Use _create instead
	void	**destroy**		Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**		Use of this method is deprecated. Use _destroyed? instead
[static]	new DCplxTrans ptr	**from_itrans**	(const CplxTrans trans, double dbu = 1)	Use of this method is deprecated. Use new instead

[const]	bool	**is_const_object?**		Use of this method is deprecated. Use _is_const_object? instead
[const]	ICplxTrans	**to_itrans**	(double dbu = 1)	Use of this method is deprecated
[const]	CplxTrans	**to_trans**	(double dbu = 1)	Use of this method is deprecated
[const]	VCplxTrans	**to_vtrans**	(double dbu = 1)	Use of this method is deprecated

Detailed description

!=

Signature: *[const]* bool **!=** (const DCplxTrans other)

Description: Tests for inequality

*****

(1) Signature: *[const]* CplxTrans ***** (const CplxTrans t)

Description: Multiplication (concatenation) of transformations

t: The transformation to apply before

Returns: The modified transformation

The * operator returns self*t ("t is applied before this transformation").

(2) Signature: *[const]* double ***** (double d)

Description: Transforms a distance

d: The distance to transform

Returns: The transformed distance

The "ctrans" method transforms the given distance. e = t(d). For the simple transformations, there is no magnification and no modification of the distance therefore.

The product '*' has been added as a synonym in version 0.28.

Python specific notes:
This method also implements '__rmul__'.

(3) Signature: *[const]* DPoint ***** (const DPoint p)

Description: Transforms a point

p: The point to transform

Returns: The transformed point

The "trans" method or the * operator transforms the given point. q = t(p)

The * operator has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(4) Signature: *[const]* DVector ***** (const DVector p)

Description: Transforms a vector

v: The vector to transform

Returns: The transformed vector

The "trans" method or the * operator transforms the given vector. w = t(v)

Vector transformation has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(5) Signature: *[const]* DBox ***** (const DBox box)

Description: Transforms a box

box:	The box to transform
Returns:	The transformed box

't*box' or 't.trans(box)' is equivalent to box.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(6) Signature: *[const]* DEdge ***** (const DEdge edge)

Description: Transforms an edge

edge:	The edge to transform
Returns:	The transformed edge

't*edge' or 't.trans(edge)' is equivalent to edge.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(7) Signature: *[const]* DPolygon ***** (const DPolygon polygon)

Description: Transforms a polygon

polygon:	The polygon to transform
Returns:	The transformed polygon

't*polygon' or 't.trans(polygon)' is equivalent to polygon.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(8) Signature: *[const]* DPath ***** (const DPath path)

Description: Transforms a path

path:	The path to transform
Returns:	The transformed path

't*path' or 't.trans(path)' is equivalent to path.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(9) Signature: *[const]* DText ***** (const DText text)

Description: Transforms a text

text:	The text to transform
Returns:	The transformed text

't*text' or 't.trans(text)' is equivalent to text.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(10) Signature: *[const]* DCplxTrans ***** (const DCplxTrans t)

Description: Returns the concatenated transformation

t:	The transformation to apply before
Returns:	The modified transformation

The * operator returns self*t ("t is applied before this transformation").

<

Signature: *[const]* bool **<** (const DCplxTrans other)

Description: Provides a 'less' criterion for sorting

This method is provided to implement a sorting order. The definition of 'less' is opaque and might change in future versions.

==

Signature: *[const]* bool **==** (const DCplxTrans other)

Description: Tests for equality

M0

Signature: *[static]* DCplxTrans **M0**

Description: A constant giving "mirrored at the x-axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M0'. This is the getter.

M135

Signature: *[static]* DCplxTrans **M135**

Description: A constant giving "mirrored at the 135 degree axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M135'. This is the getter.

M45

Signature: *[static]* DCplxTrans **M45**

Description: A constant giving "mirrored at the 45 degree axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M45'. This is the getter.

M90

Signature: *[static]* DCplxTrans **M90**

Description: A constant giving "mirrored at the y (90 degree) axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M90'. This is the getter.

R0

Signature: *[static]* DCplxTrans **R0**

Description: A constant giving "unrotated" (unit) transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R0'. This is the getter.

R180

Signature: *[static]* DCplxTrans **R180**

Description: A constant giving "rotated by 180 degree counterclockwise" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R180'. This is the getter.

R270

Signature: *[static]* DCplxTrans **R270**

Description: A constant giving "rotated by 270 degree counterclockwise" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R270'. This is the getter.

R90

Signature: *[static]* DCplxTrans **R90**

Description: A constant giving "rotated by 90 degree counterclockwise" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R90'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

angle

Signature: *[const]* double **angle**

Description: Gets the angle

Returns: The rotation angle this transformation provides in degree units (0..360 deg).

Note that the simple transformation returns the angle in units of 90 degree. Hence for a simple trans (i.e. Trans), a rotation angle of 180 degree delivers a value of 2 for the angle attribute. The complex transformation, supporting any rotation angle returns the angle in degree.

Python specific notes:
The object exposes a readable attribute 'angle'. This is the getter.

angle=

Signature: void **angle=** (double a)

Description: Sets the angle

a: The new angle

See angle for a description of that attribute.

Python specific notes:
The object exposes a writable attribute 'angle'. This is the setter.

assign

Signature: void **assign** (const DCplxTrans other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

ctrans

Signature: *[const]* double **ctrans** (double d)

Description: Transforms a distance

d: The distance to transform

Returns: The transformed distance

The "ctrans" method transforms the given distance. e = t(d). For the simple transformations, there is no magnification and no modification of the distance therefore.

The product '*' has been added as a synonym in version 0.28.

Python specific notes:
This method also implements '__rmul__'.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

disp

Signature: *[const]* DVector **disp**

Description: Gets the displacement

Python specific notes:
The object exposes a readable attribute 'disp'. This is the getter.

disp=

Signature: void **disp=** (const DVector u)

Description: Sets the displacement

u: The new displacement

Python specific notes:
The object exposes a writable attribute 'disp'. This is the setter.

dup

Signature: *[const]* new DCplxTrans ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

from_itrans

Signature: *[static]* new DCplxTrans ptr **from_itrans** (const CplxTrans trans, double dbu = 1)

Description: Creates a floating-point coordinate transformation from another coordinate flavour

Use of this method is deprecated. Use new instead

The 'dbu' argument is used to transform the input space from integer units to floating-point units. Formally, the DCplxTrans transformation is initialized with 'trans * to_dbu' where 'to_dbu' is the transformation into DBU space, or more precisely 'VCplxTrans(mag=1/dbu)'.

This constructor has been introduced in version 0.25. The 'dbu' argument has been added in version 0.29.

Python specific notes:
This method is the default initializer of the object.

from_s

Signature: *[static]* new DCplxTrans ptr **from_s** (string s)

Description: Creates an object from a string

Creates the object from a string representation (as returned by to_s)

This method has been added in version 0.23.

hash

Signature: *[const]* unsigned long **hash**

Description: Computes a hash value

Returns a hash value for the given transformation. This method enables transformations as hash keys.

This method has been introduced in version 0.25.

Python specific notes:
This method is also available as 'hash(object)'.

invert

Signature: DCplxTrans **invert**

Description: Inverts the transformation (in place)

Returns: The inverted transformation

Inverts the transformation and replaces this transformation by its inverted one.

inverted

Signature: *[const]* DCplxTrans **inverted**

Description: Returns the inverted transformation

Returns: The inverted transformation

Returns the inverted transformation. This method does not modify the transformation.

is_complex?

Signature: *[const]* bool **is_complex?**

Description: Returns true if the transformation is a complex one

If this predicate is false, the transformation can safely be converted to a simple transformation. Otherwise, this conversion will be lossy. The predicate value is equivalent to 'is_mag || !is_ortho'.

This method has been introduced in version 0.27.5.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_mag?

Signature: *[const]* bool **is_mag?**

Description: Tests, if the transformation is a magnifying one

This is the recommended test for checking if the transformation represents a magnification.

is_mirror?

Signature: *[const]* bool **is_mirror?**

Description: Gets the mirror flag

If this property is true, the transformation is composed of a mirroring at the x-axis followed by a rotation by the angle given by the angle property.

Python specific notes:

The object exposes a readable attribute 'mirror'. This is the getter.

is_ortho?

Signature: *[const]* bool **is_ortho?**

Description: Tests, if the transformation is an orthogonal transformation

If the rotation is by a multiple of 90 degree, this method will return true.

is_unity?

Signature: *[const]* bool **is_unity?**

Description: Tests, whether this is a unit transformation

mag

Signature: *[const]* double **mag**

Description: Gets the magnification

Python specific notes:
The object exposes a readable attribute 'mag'. This is the getter.

mag=

Signature: void **mag=** (double m)

Description: Sets the magnification

m: The new magnification

Python specific notes:
The object exposes a writable attribute 'mag'. This is the setter.

mirror=

Signature: void **mirror=** (bool m)

Description: Sets the mirror flag

m: The new mirror flag

"mirroring" describes a reflection at the x-axis which is included in the transformation prior to rotation.

Python specific notes:
The object exposes a writable attribute 'mirror'. This is the setter.

new

(1) Signature: *[static]* new DCplxTrans ptr **new** (const CplxTrans trans, double dbu = 1)

Description: Creates a floating-point coordinate transformation from another coordinate flavour

The 'dbu' argument is used to transform the input space from integer units to floating-point units. Formally, the DCplxTrans transformation is initialized with 'trans * to_dbu' where 'to_dbu' is the transformation into DBU space, or more precisely 'VCplxTrans(mag=1/dbu)'.

This constructor has been introduced in version 0.25. The 'dbu' argument has been added in version 0.29.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new DCplxTrans ptr **new** (const ICplxTrans trans, double dbu = 1)

Description: Creates a floating-point coordinate transformation from another coordinate flavour

The 'dbu' argument is used to transform the input and output space from integer units to floating-point units and vice versa. Formally, the DCplxTrans transformation is initialized with 'from_dbu * trans * to_dbu' where 'to_dbu' is the transformation into DBU space, or more precisely 'VCplxTrans(mag=1/dbu)'. 'from_dbu' is the transformation into micrometer space, or more precisely 'CplxTrans(mag=dbu)'.

This constructor has been introduced in version 0.25. The 'dbu' argument has been added in version 0.29.

Python specific notes:

This method is the default initializer of the object.

(3) Signature: *[static]* new DCplxTrans ptr **new** (const VCplxTrans trans, double dbu = 1)

Description: Creates a floating-point coordinate transformation from another coordinate flavour

The 'dbu' argument is used to transform the output space from integer units to floating-point units. Formally, the DCplxTrans transformation is initialized with 'from_dbu * trans' where 'from_dbu' is the transformation into micrometer space, or more precisely 'CplxTrans(mag=dbu)'.

This constructor has been introduced in version 0.25. The 'dbu' argument has been added in version 0.29.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new DCplxTrans ptr **new**

Description: Creates a unit transformation

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new DCplxTrans ptr **new** (const DCplxTrans c, double mag = 1, const DVector u = 0,0)

Description: Creates a transformation from another transformation plus a magnification and displacement

c: The original transformation

u: The Additional displacement

Creates a new transformation from a existing transformation. This constructor is provided for creating duplicates and backward compatibility since the constants are transformations now. It will copy the original transformation and add the given displacement.

This variant has been introduced in version 0.25.

Python specific notes:
This method is the default initializer of the object.

(6) Signature: *[static]* new DCplxTrans ptr **new** (const DCplxTrans c, double mag = 1, double x = 0, double y = 0)

Description: Creates a transformation from another transformation plus a magnification and displacement

c: The original transformation

x: The Additional displacement (x)

y: The Additional displacement (y)

Creates a new transformation from a existing transformation. This constructor is provided for creating duplicates and backward compatibility since the constants are transformations now. It will copy the original transformation and add the given displacement.

This variant has been introduced in version 0.25.

Python specific notes:
This method is the default initializer of the object.

(7) Signature: *[static]* new DCplxTrans ptr **new** (double x, double y)

Description: Creates a transformation from a x and y displacement

x: The x displacement

y:	The y displacement

This constructor will create a transformation with the specified displacement but no rotation.

Python specific notes:
This method is the default initializer of the object.

(8) Signature: *[static]* new DCplxTrans ptr **new** (const DTrans t, double mag = 1)

Description: Creates a transformation from a simple transformation and a magnification

Creates a magnifying transformation from a simple transformation and a magnification.

Python specific notes:
This method is the default initializer of the object.

(9) Signature: *[static]* new DCplxTrans ptr **new** (const DVector u)

Description: Creates a transformation from a displacement

Creates a transformation with a displacement only.

This method has been added in version 0.25.

Python specific notes:
This method is the default initializer of the object.

(10) Signature: *[static]* new DCplxTrans ptr **new** (double mag = 1, double rot = 0, bool mirrx = false, const DVector u = 0,0)

Description: Creates a transformation using magnification, angle, mirror flag and displacement

mag:	The magnification
rot:	The rotation angle in units of degree
mirrx:	True, if mirrored at x axis
u:	The displacement

The sequence of operations is: magnification, mirroring at x axis, rotation, application of displacement.

Python specific notes:
This method is the default initializer of the object.

(11) Signature: *[static]* new DCplxTrans ptr **new** (double mag = 1, double rot = 0, bool mirrx = false, double x = 0, double y = 0)

Description: Creates a transformation using magnification, angle, mirror flag and displacement

mag:	The magnification
rot:	The rotation angle in units of degree
mirrx:	True, if mirrored at x axis
x:	The x displacement
y:	The y displacement

The sequence of operations is: magnification, mirroring at x axis, rotation, application of displacement.

Python specific notes:
This method is the default initializer of the object.

rot

Signature: *[const]* int **rot**

Description: Returns the respective simple transformation equivalent rotation code if possible

If this transformation is orthogonal (is_ortho () == true), then this method will return the corresponding fixpoint transformation, not taking into account magnification and displacement. If the transformation is not orthogonal, the result reflects the quadrant the rotation goes into.

s_trans

Signature: *[const]* DTrans **s_trans**

Description: Extracts the simple transformation part

The simple transformation part does not reflect magnification or arbitrary angles. Rotation angles are rounded down to multiples of 90 degree. Magnification is fixed to 1.0.

to_itrans

Signature: *[const]* ICplxTrans **to_itrans** (double dbu = 1)

Description: Converts the transformation to another transformation with integer input and output coordinates

Use of this method is deprecated

The database unit can be specified to translate the floating-point coordinate displacement in micron units to an integer-coordinate displacement in database units. The displacement's' coordinates will be divided by the database unit.

This method is redundant with the conversion constructors. Instead of 'to_itrans' use the conversion constructor:

```
itrans = RBA::ICplxTrans::new(dtrans, dbu)
```

This method has been introduced in version 0.25 and was deprecated in version 0.29.

to_s

Signature: *[const]* string **to_s** (bool lazy = false, double dbu = 0)

Description: String conversion

If 'lazy' is true, some parts are omitted when not required. If a DBU is given, the output units will be micrometers.

The lazy and DBU arguments have been added in version 0.27.6.

Python specific notes:
This method is also available as 'str(object)'.

to_trans

Signature: *[const]* CplxTrans **to_trans** (double dbu = 1)

Description: Converts the transformation to another transformation with integer input coordinates

Use of this method is deprecated

This method is redundant with the conversion constructors. Instead of 'to_trans' use the conversion constructor:

```
trans = RBA::CplxTrans::new(dtrans, dbu)
```

This method has been introduced in version 0.25 and was deprecated in version 0.29.

to_vtrans

Signature: *[const]* VCplxTrans **to_vtrans** (double dbu = 1)

Description: Converts the transformation to another transformation with integer output coordinates

Use of this method is deprecated

The database unit can be specified to translate the floating-point coordinate displacement in micron units to an integer-coordinate displacement in database units. The displacement's' coordinates will be divided by the database unit.

This method is redundant with the conversion constructors. Instead of 'to_vtrans' use the conversion constructor:

```
vtrans = RBA::VCplxTrans::new(dtrans, dbu)
```

This method has been introduced in version 0.25 and was deprecated in version 0.29.

trans

(1) Signature: *[const]* DPoint **trans** (const DPoint p)

Description: Transforms a point

p:	The point to transform
Returns:	The transformed point

The "trans" method or the * operator transforms the given point. q = t(p)

The * operator has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(2) Signature: *[const]* DVector **trans** (const DVector p)

Description: Transforms a vector

v:	The vector to transform
Returns:	The transformed vector

The "trans" method or the * operator transforms the given vector. w = t(v)

Vector transformation has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(3) Signature: *[const]* DBox **trans** (const DBox box)

Description: Transforms a box

box:	The box to transform
Returns:	The transformed box

't*box' or 't.trans(box)' is equivalent to box.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(4) Signature: *[const]* DEdge **trans** (const DEdge edge)

Description: Transforms an edge

edge:	The edge to transform
Returns:	The transformed edge

't*edge' or 't.trans(edge)' is equivalent to edge.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:

This method also implements '__rmul__'.

(5) Signature: *[const]* DPolygon **trans** (const DPolygon polygon)

Description: Transforms a polygon

polygon:	The polygon to transform
Returns:	The transformed polygon

't*polygon' or 't.trans(polygon)' is equivalent to polygon.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(6) Signature: *[const]* DPath **trans** (const DPath path)

Description: Transforms a path

path:	The path to transform
Returns:	The transformed path

't*path' or 't.trans(path)' is equivalent to path.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(7) Signature: *[const]* DText **trans** (const DText text)

Description: Transforms a text

text:	The text to transform
Returns:	The transformed text

't*text' or 't.trans(text)' is equivalent to text.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

4.108. API reference - Class CplxTrans

Notation used in Ruby API documentation

Module: db

Description: A complex transformation

A complex transformation provides magnification, mirroring at the x-axis, rotation by an arbitrary angle and a displacement. This is also the order, the operations are applied. This version can transform integer-coordinate objects into floating-point coordinate objects. This is the generic and exact case, for example for non-integer magnifications.

Complex transformations are extensions of the simple transformation classes (Trans or DTrans in that case) and behave similar.

Transformations can be used to transform points or other objects. Transformations can be combined with the '*' operator to form the transformation which is equivalent to applying the second and then the first. Here is some code:

```
# Create a transformation that applies a magnification of 1.5, a rotation by 90 degree
# and displacement of 10 in x and 20 units in y direction:
t = RBA::DCplxTrans::new(1.5, 90, false, 10.0, 20.0)
t.to_s            # r90 *1.5 10,20
# compute the inverse:
t.inverted.to_s   # r270 *0.666666667 -13,7
# Combine with another displacement (applied after that):
(RBA::DCplxTrans::new(5, 5) * t).to_s    # r90 *1.5 15,25
# Transform a point:
t.trans(RBA::DPoint::new(100, 200)).to_s # -290,170
```

The inverse type of the CplxTrans type is VCplxTrans which will transform floating-point to integer coordinate objects. Transformations of CplxTrans type can be concatenated (operator *) with either itself or with transformations of compatible input or output type. This means, the operator CplxTrans * ICplxTrans is allowed (output types of ICplxTrans and input of CplxTrans are identical) while CplxTrans * DCplxTrans is not. See The Database API for more details about the database objects.

Public constructors

new CplxTrans ptr	**new**	(const DCplxTrans trans, double dbu = 1)	Creates an integer-to-floating-point coordinate transformation from another coordinate flavour
new CplxTrans ptr	**new**	(const ICplxTrans trans, double dbu = 1)	Creates an integer-to-floating-point coordinate transformation from another coordinate flavour
new CplxTrans ptr	**new**	(const VCplxTrans trans, double dbu = 1)	Creates an integer-to-floating-point coordinate transformation from another coordinate flavour
new CplxTrans ptr	**new**		Creates a unit transformation
new CplxTrans ptr	**new**	(const CplxTrans c, double mag = 1, const DVector u = 0,0)	Creates a transformation from another transformation plus a magnification and displacement
new CplxTrans ptr	**new**	(const CplxTrans c, double mag = 1, double x = 0, double y = 0)	Creates a transformation from another transformation plus a magnification and displacement
new CplxTrans ptr	**new**	(double x, double y)	Creates a transformation from a x and y displacement
new CplxTrans ptr	**new**	(const Trans t, double mag = 1)	Creates a transformation from a simple transformation and a magnification

new CplxTrans ptr	new	(const DVector u)	Creates a transformation from a displacement
new CplxTrans ptr	new	(double mag = 1, double rot = 0, bool mirrx = false, const DVector u = 0,0)	Creates a transformation using magnification, angle, mirror flag and displacement
new CplxTrans ptr	new	(double mag = 1, double rot = 0, bool mirrx = false, double x = 0, double y = 0)	Creates a transformation using magnification, angle, mirror flag and displacement

Public methods

[const]	bool	!=	(const CplxTrans other)	Tests for inequality
[const]	DCplxTrans	*	(const VCplxTrans t)	Multiplication (concatenation) of transformations
[const]	CplxTrans	*	(const ICplxTrans t)	Multiplication (concatenation) of transformations
[const]	double	*	(unsigned int d)	Transforms a distance
[const]	DPoint	*	(const Point p)	Transforms a point
[const]	DVector	*	(const Vector p)	Transforms a vector
[const]	DBox	*	(const Box box)	Transforms a box
[const]	DEdge	*	(const Edge edge)	Transforms an edge
[const]	DPolygon	*	(const Polygon polygon)	Transforms a polygon
[const]	DPath	*	(const Path path)	Transforms a path
[const]	DText	*	(const Text text)	Transforms a text
[const]	CplxTrans	*	(const CplxTrans t)	Returns the concatenated transformation
[const]	bool	<	(const CplxTrans other)	Provides a 'less' criterion for sorting
[const]	bool	==	(const CplxTrans other)	Tests for equality
	void	_create		Ensures the C++ object is created
	void	_destroy		Explicitly destroys the object
[const]	bool	_destroyed?		Returns a value indicating whether the object was already destroyed

[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	double	**angle**		Gets the angle
	void	**angle=**	(double a)	Sets the angle
	void	**assign**	(const CplxTrans other)	Assigns another object to self
[const]	double	**ctrans**	(unsigned int d)	Transforms a distance
[const]	DVector	**disp**		Gets the displacement
	void	**disp=**	(const DVector u)	Sets the displacement
[const]	new CplxTrans ptr	**dup**		Creates a copy of self
[const]	unsigned long	**hash**		Computes a hash value
	CplxTrans	**invert**		Inverts the transformation (in place)
[const]	VCplxTrans	**inverted**		Returns the inverted transformation
[const]	bool	**is_complex?**		Returns true if the transformation is a complex one
[const]	bool	**is_mag?**		Tests, if the transformation is a magnifying one
[const]	bool	**is_mirror?**		Gets the mirror flag
[const]	bool	**is_ortho?**		Tests, if the transformation is an orthogonal transformation
[const]	bool	**is_unity?**		Tests, whether this is a unit transformation
[const]	double	**mag**		Gets the magnification
	void	**mag=**	(double m)	Sets the magnification
	void	**mirror=**	(bool m)	Sets the mirror flag
[const]	int	**rot**		Returns the respective simple transformation equivalent rotation code if possible
[const]	Trans	**s_trans**		Extracts the simple transformation part
[const]	string	**to_s**	(bool lazy = false, double dbu = 0)	String conversion

[const]	DPoint	**trans**	(const Point p)	Transforms a point
[const]	DVector	**trans**	(const Vector p)	Transforms a vector
[const]	DBox	**trans**	(const Box box)	Transforms a box
[const]	DEdge	**trans**	(const Edge edge)	Transforms an edge
[const]	DPolygon	**trans**	(const Polygon polygon)	Transforms a polygon
[const]	DPath	**trans**	(const Path path)	Transforms a path
[const]	DText	**trans**	(const Text text)	Transforms a text

Public static methods and constants

	CplxTrans	**M0**		A constant giving "mirrored at the x-axis" transformation
	CplxTrans	**M135**		A constant giving "mirrored at the 135 degree axis" transformation
	CplxTrans	**M45**		A constant giving "mirrored at the 45 degree axis" transformation
	CplxTrans	**M90**		A constant giving "mirrored at the y (90 degree) axis" transformation
	CplxTrans	**R0**		A constant giving "unrotated" (unit) transformation
	CplxTrans	**R180**		A constant giving "rotated by 180 degree counterclockwise" transformation
	CplxTrans	**R270**		A constant giving "rotated by 270 degree counterclockwise" transformation
	CplxTrans	**R90**		A constant giving "rotated by 90 degree counterclockwise" transformation
	new CplxTrans ptr	**from_s**	(string s)	Creates an object from a string

Detailed description

!=

Signature: *[const]* bool **!=** (const CplxTrans other)

Description: Tests for inequality

*****

(1) Signature: *[const]* DCplxTrans ***** (const VCplxTrans t)

Description: Multiplication (concatenation) of transformations

t: The transformation to apply before

Returns: The modified transformation

The * operator returns self*t ("t is applied before this transformation").

(2) Signature: *[const]* CplxTrans ***** (const ICplxTrans t)

Description: Multiplication (concatenation) of transformations

t: The transformation to apply before

Returns: The modified transformation

The * operator returns self*t ("t is applied before this transformation").

(3) Signature: *[const]* double ***** (unsigned int d)

Description: Transforms a distance

d: The distance to transform

Returns: The transformed distance

The "ctrans" method transforms the given distance. e = t(d). For the simple transformations, there is no magnification and no modification of the distance therefore.

The product '*' has been added as a synonym in version 0.28.

Python specific notes:
This method also implements '__rmul__'.

(4) Signature: *[const]* DPoint ***** (const Point p)

Description: Transforms a point

p: The point to transform

Returns: The transformed point

The "trans" method or the * operator transforms the given point. q = t(p)

The * operator has been introduced in version 0.25.

Python specific notes:

This method also implements '__rmul__'.

(5) Signature: *[const]* DVector ***** (const Vector p)

Description: Transforms a vector

v:	The vector to transform
Returns:	The transformed vector

The "trans" method or the * operator transforms the given vector. w = t(v)

Vector transformation has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(6) Signature: *[const]* DBox ***** (const Box box)

Description: Transforms a box

box:	The box to transform
Returns:	The transformed box

't*box' or 't.trans(box)' is equivalent to box.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(7) Signature: *[const]* DEdge ***** (const Edge edge)

Description: Transforms an edge

edge:	The edge to transform
Returns:	The transformed edge

't*edge' or 't.trans(edge)' is equivalent to edge.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(8) Signature: *[const]* DPolygon ***** (const Polygon polygon)

Description: Transforms a polygon

polygon:	The polygon to transform
Returns:	The transformed polygon

't*polygon' or 't.trans(polygon)' is equivalent to polygon.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(9) Signature: *[const]* DPath ***** (const Path path)

Description: Transforms a path

path:	The path to transform
Returns:	The transformed path

't*path' or 't.trans(path)' is equivalent to path.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(10) Signature: *[const]* DText ***** (const Text text)

Description: Transforms a text

text:	The text to transform
Returns:	The transformed text

't*text' or 't.trans(text)' is equivalent to text.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(11) Signature: *[const]* CplxTrans ***** (const CplxTrans t)

Description: Returns the concatenated transformation

t:	The transformation to apply before
Returns:	The modified transformation

The * operator returns self*t ("t is applied before this transformation").

<

Signature: *[const]* bool **<** (const CplxTrans other)

Description: Provides a 'less' criterion for sorting

This method is provided to implement a sorting order. The definition of 'less' is opaque and might change in future versions.

==

Signature: *[const]* bool **==** (const CplxTrans other)

Description: Tests for equality

M0

Signature: *[static]* CplxTrans **M0**

Description: A constant giving "mirrored at the x-axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M0'. This is the getter.

M135

Signature: *[static]* CplxTrans **M135**

Description: A constant giving "mirrored at the 135 degree axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M135'. This is the getter.

M45

Signature: *[static]* CplxTrans **M45**

Description: A constant giving "mirrored at the 45 degree axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M45'. This is the getter.

M90

Signature: *[static]* CplxTrans **M90**

Description: A constant giving "mirrored at the y (90 degree) axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M90'. This is the getter.

R0

Signature: *[static]* CplxTrans **R0**

Description: A constant giving "unrotated" (unit) transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R0'. This is the getter.

R180

Signature: *[static]* CplxTrans **R180**

Description: A constant giving "rotated by 180 degree counterclockwise" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R180'. This is the getter.

R270

Signature: *[static]* CplxTrans **R270**

Description: A constant giving "rotated by 270 degree counterclockwise" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R270'. This is the getter.

R90

Signature: *[static]* CplxTrans **R90**

Description: A constant giving "rotated by 90 degree counterclockwise" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R90'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

angle

Signature: *[const]* double **angle**

Description: Gets the angle

Returns: The rotation angle this transformation provides in degree units (0..360 deg).

Note that the simple transformation returns the angle in units of 90 degree. Hence for a simple trans (i.e. Trans), a rotation angle of 180 degree delivers a value of 2 for the angle attribute. The complex transformation, supporting any rotation angle returns the angle in degree.

Python specific notes:
The object exposes a readable attribute 'angle'. This is the getter.

angle=

Signature: void **angle=** (double a)

Description: Sets the angle

a: The new angle

See angle for a description of that attribute.

Python specific notes:
The object exposes a writable attribute 'angle'. This is the setter.

assign

Signature: void **assign** (const CplxTrans other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

ctrans

Signature: *[const]* double **ctrans** (unsigned int d)

Description: Transforms a distance

d: The distance to transform

Returns: The transformed distance

The "ctrans" method transforms the given distance. e = t(d). For the simple transformations, there is no magnification and no modification of the distance therefore.

The product '*' has been added as a synonym in version 0.28.

Python specific notes:
This method also implements '__rmul__'.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

disp

Signature: *[const]* DVector **disp**

Description: Gets the displacement

Python specific notes:
The object exposes a readable attribute 'disp'. This is the getter.

disp=

Signature: void **disp=** (const DVector u)

Description: Sets the displacement

u: The new displacement

Python specific notes:
The object exposes a writable attribute 'disp'. This is the setter.

dup

Signature: *[const]* new CplxTrans ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

from_dtrans

Signature: *[static]* new CplxTrans ptr **from_dtrans** (const DCplxTrans trans, double dbu = 1)

Description: Creates an integer-to-floating-point coordinate transformation from another coordinate flavour

Use of this method is deprecated. Use new instead

The 'dbu' argument is used to transform the input space from floating-point units to integer units. Formally, the CplxTrans transformation is initialized with 'trans * from_dbu' where 'from_dbu' is the transformation into micrometer space, or more precisely 'CplxTrans(mag=dbu)'.

This constructor has been introduced in version 0.25. The 'dbu' argument has been added in version 0.29.

Python specific notes:
This method is the default initializer of the object.

from_s

Signature: *[static]* new CplxTrans ptr **from_s** (string s)

Description: Creates an object from a string

Creates the object from a string representation (as returned by to_s)

This method has been added in version 0.23.

hash

Signature: *[const]* unsigned long **hash**

Description: Computes a hash value

Returns a hash value for the given transformation. This method enables transformations as hash keys.

This method has been introduced in version 0.25.

Python specific notes:
This method is also available as 'hash(object)'.

invert

Signature: CplxTrans **invert**

Description: Inverts the transformation (in place)

Returns: The inverted transformation

Inverts the transformation and replaces this transformation by its inverted one.

inverted

Signature: *[const]* VCplxTrans **inverted**

Description: Returns the inverted transformation

Returns: The inverted transformation

Returns the inverted transformation. This method does not modify the transformation.

is_complex?

Signature: *[const]* bool **is_complex?**

Description: Returns true if the transformation is a complex one

If this predicate is false, the transformation can safely be converted to a simple transformation. Otherwise, this conversion will be lossy. The predicate value is equivalent to 'is_mag || !is_ortho'.

This method has been introduced in version 0.27.5.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_mag?

Signature: *[const]* bool **is_mag?**

Description: Tests, if the transformation is a magnifying one

This is the recommended test for checking if the transformation represents a magnification.

is_mirror?

Signature: *[const]* bool **is_mirror?**

Description: Gets the mirror flag

If this property is true, the transformation is composed of a mirroring at the x-axis followed by a rotation by the angle given by the angle property.

Python specific notes:
The object exposes a readable attribute 'mirror'. This is the getter.

is_ortho?

Signature: *[const]* bool **is_ortho?**

Description: Tests, if the transformation is an orthogonal transformation

If the rotation is by a multiple of 90 degree, this method will return true.

is_unity?

Signature: *[const]* bool **is_unity?**

Description: Tests, whether this is a unit transformation

mag

Signature: *[const]* double **mag**

Description: Gets the magnification

Python specific notes:
The object exposes a readable attribute 'mag'. This is the getter.

mag=

Signature: void **mag=** (double m)

Description: Sets the magnification

m: The new magnification

Python specific notes:
The object exposes a writable attribute 'mag'. This is the setter.

mirror=

Signature: void **mirror=** (bool m)

Description: Sets the mirror flag

m: The new mirror flag

"mirroring" describes a reflection at the x-axis which is included in the transformation prior to rotation.

Python specific notes:
The object exposes a writable attribute 'mirror'. This is the setter.

new

(1) Signature: *[static]* new CplxTrans ptr **new** (const DCplxTrans trans, double dbu = 1)

Description: Creates an integer-to-floating-point coordinate transformation from another coordinate flavour

The 'dbu' argument is used to transform the input space from floating-point units to integer units. Formally, the CplxTrans transformation is initialized with 'trans * from_dbu' where 'from_dbu' is the transformation into micrometer space, or more precisely 'CplxTrans(mag=dbu)'.

This constructor has been introduced in version 0.25. The 'dbu' argument has been added in version 0.29.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new CplxTrans ptr **new** (const ICplxTrans trans, double dbu = 1)

Description: Creates an integer-to-floating-point coordinate transformation from another coordinate flavour

The 'dbu' argument is used to transform the output space from integer units to floating-point units. Formally, the CplxTrans transformation is initialized with 'from_dbu * trans' where 'from_dbu' is the transformation into micrometer space, or more precisely 'CplxTrans(mag=dbu)'.

This constructor has been introduced in version 0.25. The 'dbu' argument has been added in version 0.29.

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new CplxTrans ptr **new** (const VCplxTrans trans, double dbu = 1)

Description: Creates an integer-to-floating-point coordinate transformation from another coordinate flavour

The 'dbu' argument is used to transform the input and output space from integer units to floating-point units and vice versa. Formally, the DCplxTrans transformation is initialized with 'from_dbu * trans * from_dbu' where 'from_dbu' is the transformation into micrometer space, or more precisely 'CplxTrans(mag=dbu)'.

This constructor has been introduced in version 0.25. The 'dbu' argument has been added in version 0.29.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new CplxTrans ptr **new**

Description: Creates a unit transformation

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new CplxTrans ptr **new** (const CplxTrans c, double mag = 1, const DVector u = 0,0)

Description: Creates a transformation from another transformation plus a magnification and displacement

c:	The original transformation
u:	The Additional displacement

Creates a new transformation from a existing transformation. This constructor is provided for creating duplicates and backward compatibility since the constants are transformations now. It will copy the original transformation and add the given displacement.

This variant has been introduced in version 0.25.

Python specific notes:
This method is the default initializer of the object.

(6) Signature: *[static]* new CplxTrans ptr **new** (const CplxTrans c, double mag = 1, double x = 0, double y = 0)

Description: Creates a transformation from another transformation plus a magnification and displacement

c:	The original transformation
x:	The Additional displacement (x)
y:	The Additional displacement (y)

Creates a new transformation from a existing transformation. This constructor is provided for creating duplicates and backward compatibility since the constants are transformations now. It will copy the original transformation and add the given displacement.

This variant has been introduced in version 0.25.

Python specific notes:
This method is the default initializer of the object.

(7) Signature: *[static]* new CplxTrans ptr **new** (double x, double y)

Description: Creates a transformation from a x and y displacement

x:	The x displacement
y:	The y displacement

This constructor will create a transformation with the specified displacement but no rotation.

Python specific notes:
This method is the default initializer of the object.

(8) Signature: *[static]* new CplxTrans ptr **new** (const Trans t, double mag = 1)

Description: Creates a transformation from a simple transformation and a magnification

Creates a magnifying transformation from a simple transformation and a magnification.

Python specific notes:
This method is the default initializer of the object.

(9) Signature: *[static]* new CplxTrans ptr **new** (const DVector u)

Description: Creates a transformation from a displacement

Creates a transformation with a displacement only.

This method has been added in version 0.25.

Python specific notes:
This method is the default initializer of the object.

(10) Signature: *[static]* new CplxTrans ptr **new** (double mag = 1, double rot = 0, bool mirrx = false, const DVector u = 0,0)

Description: Creates a transformation using magnification, angle, mirror flag and displacement

mag:	The magnification
rot:	The rotation angle in units of degree
mirrx:	True, if mirrored at x axis
u:	The displacement

The sequence of operations is: magnification, mirroring at x axis, rotation, application of displacement.

Python specific notes:
This method is the default initializer of the object.

(11) Signature: *[static]* new CplxTrans ptr **new** (double mag = 1, double rot = 0, bool mirrx = false, double x = 0, double y = 0)

Description: Creates a transformation using magnification, angle, mirror flag and displacement

mag:	The magnification
rot:	The rotation angle in units of degree
mirrx:	True, if mirrored at x axis

x: The x displacement

y: The y displacement

The sequence of operations is: magnification, mirroring at x axis, rotation, application of displacement.

Python specific notes:
This method is the default initializer of the object.

rot

Signature: *[const]* int **rot**

Description: Returns the respective simple transformation equivalent rotation code if possible

If this transformation is orthogonal (is_ortho () == true), then this method will return the corresponding fixpoint transformation, not taking into account magnification and displacement. If the transformation is not orthogonal, the result reflects the quadrant the rotation goes into.

s_trans

Signature: *[const]* Trans **s_trans**

Description: Extracts the simple transformation part

The simple transformation part does not reflect magnification or arbitrary angles. Rotation angles are rounded down to multiples of 90 degree. Magnification is fixed to 1.0.

to_itrans

Signature: *[const]* ICplxTrans **to_itrans** (double dbu = 1)

Description: Converts the transformation to another transformation with integer input and output coordinates

Use of this method is deprecated

This method is redundant with the conversion constructors. Instead of 'to_itrans' use the conversion constructor:

```
itrans = RBA::ICplxTrans::new(trans, dbu)
```

This method has been introduced in version 0.25 and was deprecated in version 0.29.

to_s

Signature: *[const]* string **to_s** (bool lazy = false, double dbu = 0)

Description: String conversion

If 'lazy' is true, some parts are omitted when not required. If a DBU is given, the output units will be micrometers.

The lazy and DBU arguments have been added in version 0.27.6.

Python specific notes:
This method is also available as 'str(object)'.

to_trans

Signature: *[const]* DCplxTrans **to_trans** (double dbu = 1)

Description: Converts the transformation to another transformation with floating-point input coordinates

Use of this method is deprecated

This method is redundant with the conversion constructors. Instead of 'to_trans' use the conversion constructor:

```
dtrans = RBA::DCplxTrans::new(trans, dbu)
```

This method has been introduced in version 0.25 and was deprecated in version 0.29.

to_vtrans

Signature: *[const]* VCplxTrans **to_vtrans** (double dbu = 1)

Description: Converts the transformation to another transformation with integer output and floating-point input coordinates

Use of this method is deprecated

This method is redundant with the conversion constructors. Instead of 'to_vtrans' use the conversion constructor:

```
vtrans = RBA::VCplxTrans::new(trans, dbu)
```

This method has been introduced in version 0.25 and was deprecated in version 0.29.

trans

(1) Signature: *[const]* DPoint **trans** (const Point p)

Description: Transforms a point

p:	The point to transform
Returns:	The transformed point

The "trans" method or the * operator transforms the given point. q = t(p)

The * operator has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(2) Signature: *[const]* DVector **trans** (const Vector p)

Description: Transforms a vector

v:	The vector to transform
Returns:	The transformed vector

The "trans" method or the * operator transforms the given vector. w = t(v)

Vector transformation has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(3) Signature: *[const]* DBox **trans** (const Box box)

Description: Transforms a box

box:	The box to transform
Returns:	The transformed box

't*box' or 't.trans(box)' is equivalent to box.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(4) Signature: *[const]* DEdge **trans** (const Edge edge)

Description: Transforms an edge

edge:	The edge to transform
Returns:	The transformed edge

't*edge' or 't.trans(edge)' is equivalent to edge.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(5) Signature: *[const]* DPolygon **trans** (const Polygon polygon)

Description: Transforms a polygon

polygon:	The polygon to transform
Returns:	The transformed polygon

't*polygon' or 't.trans(polygon)' is equivalent to polygon.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(6) Signature: *[const]* DPath **trans** (const Path path)

Description: Transforms a path

path:	The path to transform
Returns:	The transformed path

't*path' or 't.trans(path)' is equivalent to path.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(7) Signature: *[const]* DText **trans** (const Text text)

Description: Transforms a text

text:	The text to transform
Returns:	The transformed text

't*text' or 't.trans(text)' is equivalent to text.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

4.109. API reference - Class ICplxTrans

Notation used in Ruby API documentation

Module: db

Description: A complex transformation

A complex transformation provides magnification, mirroring at the x-axis, rotation by an arbitrary angle and a displacement. This is also the order, the operations are applied. This version can transform integer-coordinate objects into the same, which may involve rounding and can be inexact.

Complex transformations are extensions of the simple transformation classes (Trans in that case) and behave similar.

Transformations can be used to transform points or other objects. Transformations can be combined with the '*' operator to form the transformation which is equivalent to applying the second and then the first. Here is some code:

```
# Create a transformation that applies a magnification of 1.5, a rotation by 90 degree
# and displacement of 10 in x and 20 units in y direction:
t = RBA::ICplxTrans::new(1.5, 90, false, 10.0, 20.0)
t.to_s            # r90 *1.5 10,20
# compute the inverse:
t.inverted.to_s   # r270 *0.666666667 -13,7
# Combine with another displacement (applied after that):
(RBA::ICplxTrans::new(5, 5) * t).to_s    # r90 *1.5 15,25
# Transform a point:
t.trans(RBA::Point::new(100, 200)).to_s  # -290,170
```

This class has been introduced in version 0.18.

See The Database API for more details about the database objects.

Public constructors

new ICplxTrans ptr	**new**	(const DCplxTrans trans, double dbu = 1)	Creates an integer coordinate transformation from another coordinate flavour
new ICplxTrans ptr	**new**	(const CplxTrans trans, double dbu = 1)	Creates an integer coordinate transformation from another coordinate flavour
new ICplxTrans ptr	**new**	(const VCplxTrans trans, double dbu = 1)	Creates an integer coordinate transformation from another coordinate flavour
new ICplxTrans ptr	**new**		Creates a unit transformation
new ICplxTrans ptr	**new**	(const ICplxTrans c, double mag = 1, const Vector u = 0,0)	Creates a transformation from another transformation plus a magnification and displacement
new ICplxTrans ptr	**new**	(const ICplxTrans c, double mag = 1, int x = 0, int y = 0)	Creates a transformation from another transformation plus a magnification and displacement
new ICplxTrans ptr	**new**	(int x, int y)	Creates a transformation from a x and y displacement
new ICplxTrans ptr	**new**	(const Trans t, double mag = 1)	Creates a transformation from a simple transformation and a magnification

new ICplxTrans ptr	new	(const Vector u)	Creates a transformation from a displacement
new ICplxTrans ptr	new	(double mag = 1, double rot = 0, bool mirrx = false, const Vector u = 0,0)	Creates a transformation using magnification, angle, mirror flag and displacement
new ICplxTrans ptr	new	(double mag = 1, double rot = 0, bool mirrx = false, int x = 0, int y = 0)	Creates a transformation using magnification, angle, mirror flag and displacement

Public methods

[const]	bool	!=	(const ICplxTrans other)	Tests for inequality
[const]	VCplxTrans	*	(const VCplxTrans t)	Multiplication (concatenation) of transformations
[const]	unsigned int	*	(unsigned int d)	Transforms a distance
[const]	Point	*	(const Point p)	Transforms a point
[const]	Vector	*	(const Vector p)	Transforms a vector
[const]	Box	*	(const Box box)	Transforms a box
[const]	Edge	*	(const Edge edge)	Transforms an edge
[const]	Polygon	*	(const Polygon polygon)	Transforms a polygon
[const]	Path	*	(const Path path)	Transforms a path
[const]	Text	*	(const Text text)	Transforms a text
[const]	ICplxTrans	*	(const ICplxTrans t)	Returns the concatenated transformation
[const]	bool	<	(const ICplxTrans other)	Provides a 'less' criterion for sorting
[const]	bool	==	(const ICplxTrans other)	Tests for equality
	void	_create		Ensures the C++ object is created
	void	_destroy		Explicitly destroys the object
[const]	bool	_destroyed?		Returns a value indicating whether the object was already destroyed
[const]	bool	_is_const_object?		Returns a value indicating whether the reference is a const reference

	void	_manage		Marks the object as managed by the script side.
	void	_unmanage		Marks the object as no longer owned by the script side.
[const]	double	angle		Gets the angle
	void	angle=	(double a)	Sets the angle
	void	assign	(const ICplxTrans other)	Assigns another object to self
[const]	unsigned int	ctrans	(unsigned int d)	Transforms a distance
[const]	Vector	disp		Gets the displacement
	void	disp=	(const Vector u)	Sets the displacement
[const]	new ICplxTrans ptr	dup		Creates a copy of self
[const]	unsigned long	hash		Computes a hash value
	ICplxTrans	invert		Inverts the transformation (in place)
[const]	ICplxTrans	inverted		Returns the inverted transformation
[const]	bool	is_complex?		Returns true if the transformation is a complex one
[const]	bool	is_mag?		Tests, if the transformation is a magnifying one
[const]	bool	is_mirror?		Gets the mirror flag
[const]	bool	is_ortho?		Tests, if the transformation is an orthogonal transformation
[const]	bool	is_unity?		Tests, whether this is a unit transformation
[const]	double	mag		Gets the magnification
	void	mag=	(double m)	Sets the magnification
	void	mirror=	(bool m)	Sets the mirror flag
[const]	int	rot		Returns the respective simple transformation equivalent rotation code if possible
[const]	Trans	s_trans		Extracts the simple transformation part
[const]	string	to_s	(bool lazy = false, double dbu = 0)	String conversion
[const]	Point	trans	(const Point p)	Transforms a point

[const]	Vector	**trans**	(const Vector p)	Transforms a vector
[const]	Box	**trans**	(const Box box)	Transforms a box
[const]	Edge	**trans**	(const Edge edge)	Transforms an edge
[const]	Polygon	**trans**	(const Polygon polygon)	Transforms a polygon
[const]	Path	**trans**	(const Path path)	Transforms a path
[const]	Text	**trans**	(const Text text)	Transforms a text

Public static methods and constants

	ICplxTrans	**M0**		A constant giving "mirrored at the x-axis" transformation
	ICplxTrans	**M135**		A constant giving "mirrored at the 135 degree axis" transformation
	ICplxTrans	**M45**		A constant giving "mirrored at the 45 degree axis" transformation
	ICplxTrans	**M90**		A constant giving "mirrored at the y (90 degree) axis" transformation
	ICplxTrans	**R0**		A constant giving "unrotated" (unit) transformation
	ICplxTrans	**R180**		A constant giving "rotated by 180 degree counterclockwise" transformation
	ICplxTrans	**R270**		A constant giving "rotated by 270 degree counterclockwise" transformation
	ICplxTrans	**R90**		A constant giving "rotated by 90 degree counterclockwise" transformation
	new ICplxTrans ptr	**from_s**	(string s)	Creates an object from a string

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**		Use of this method is deprecated. Use _create instead
	void	**destroy**		Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**		Use of this method is deprecated. Use _destroyed? instead
[static]	new ICplxTrans ptr	**from_dtrans**	(const DCplxTrans trans, double dbu = 1)	Use of this method is deprecated. Use new instead

Detailed description

!=

Signature: *[const]* bool **!=** (const ICplxTrans other)

Description: Tests for inequality

*****

(1) Signature: *[const]* VCplxTrans ***** (const VCplxTrans t)

Description: Multiplication (concatenation) of transformations

t: The transformation to apply before

Returns: The modified transformation

The * operator returns self*t ("t is applied before this transformation").

(2) Signature: *[const]* unsigned int ***** (unsigned int d)

Description: Transforms a distance

d: The distance to transform

Returns: The transformed distance

The "ctrans" method transforms the given distance. e = t(d). For the simple transformations, there is no magnification and no modification of the distance therefore.

The product '*' has been added as a synonym in version 0.28.

Python specific notes:
This method also implements '__rmul__'.

(3) Signature: *[const]* Point ***** (const Point p)

Description: Transforms a point

p: The point to transform

Returns: The transformed point

The "trans" method or the * operator transforms the given point. q = t(p)

The * operator has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(4) Signature: *[const]* Vector ***** (const Vector p)

Description: Transforms a vector

v: The vector to transform

Returns: The transformed vector

The "trans" method or the * operator transforms the given vector. w = t(v)

Vector transformation has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(5) Signature: *[const]* Box * (const Box box)

Description: Transforms a box

box:	The box to transform
Returns:	The transformed box

't*box' or 't.trans(box)' is equivalent to box.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(6) Signature: *[const]* Edge * (const Edge edge)

Description: Transforms an edge

edge:	The edge to transform
Returns:	The transformed edge

't*edge' or 't.trans(edge)' is equivalent to edge.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(7) Signature: *[const]* Polygon * (const Polygon polygon)

Description: Transforms a polygon

polygon:	The polygon to transform
Returns:	The transformed polygon

't*polygon' or 't.trans(polygon)' is equivalent to polygon.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(8) Signature: *[const]* Path * (const Path path)

Description: Transforms a path

path:	The path to transform
Returns:	The transformed path

't*path' or 't.trans(path)' is equivalent to path.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(9) Signature: *[const]* Text * (const Text text)

Description: Transforms a text

text:	The text to transform
Returns:	The transformed text

't*text' or 't.trans(text)' is equivalent to text.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(10) Signature: *[const]* ICplxTrans ***** (const ICplxTrans t)

Description: Returns the concatenated transformation

t:	The transformation to apply before
Returns:	The modified transformation

The * operator returns self*t ("t is applied before this transformation").

<

Signature: *[const]* bool **<** (const ICplxTrans other)

Description: Provides a 'less' criterion for sorting

This method is provided to implement a sorting order. The definition of 'less' is opaque and might change in future versions.

==

Signature: *[const]* bool **==** (const ICplxTrans other)

Description: Tests for equality

M0

Signature: *[static]* ICplxTrans **M0**

Description: A constant giving "mirrored at the x-axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M0'. This is the getter.

M135

Signature: *[static]* ICplxTrans **M135**

Description: A constant giving "mirrored at the 135 degree axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M135'. This is the getter.

M45

Signature: *[static]* ICplxTrans **M45**

Description: A constant giving "mirrored at the 45 degree axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M45'. This is the getter.

M90

Signature: *[static]* ICplxTrans **M90**

Description: A constant giving "mirrored at the y (90 degree) axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M90'. This is the getter.

R0

Signature: *[static]* ICplxTrans **R0**

Description: A constant giving "unrotated" (unit) transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R0'. This is the getter.

R180

Signature: *[static]* ICplxTrans **R180**

Description: A constant giving "rotated by 180 degree counterclockwise" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R180'. This is the getter.

R270

Signature: *[static]* ICplxTrans **R270**

Description: A constant giving "rotated by 270 degree counterclockwise" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R270'. This is the getter.

R90

Signature: *[static]* ICplxTrans **R90**

Description: A constant giving "rotated by 90 degree counterclockwise" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R90'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

angle

Signature: *[const]* double **angle**

Description: Gets the angle

Returns: The rotation angle this transformation provides in degree units (0..360 deg).

Note that the simple transformation returns the angle in units of 90 degree. Hence for a simple trans (i.e. Trans), a rotation angle of 180 degree delivers a value of 2 for the angle attribute. The complex transformation, supporting any rotation angle returns the angle in degree.

Python specific notes:
The object exposes a readable attribute 'angle'. This is the getter.

angle=

Signature: void **angle=** (double a)

Description: Sets the angle

a: The new angle

See angle for a description of that attribute.

Python specific notes:
The object exposes a writable attribute 'angle'. This is the setter.

assign

Signature: void **assign** (const ICplxTrans other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

ctrans

Signature: *[const]* unsigned int **ctrans** (unsigned int d)

Description: Transforms a distance

d: The distance to transform

Returns: The transformed distance

The "ctrans" method transforms the given distance. e = t(d). For the simple transformations, there is no magnification and no modification of the distance therefore.

The product '*' has been added as a synonym in version 0.28.

Python specific notes:
This method also implements '__rmul__'.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

disp

Signature: *[const]* Vector **disp**

Description: Gets the displacement

Python specific notes:
The object exposes a readable attribute 'disp'. This is the getter.

disp=

Signature: void **disp=** (const Vector u)

Description: Sets the displacement

u: The new displacement

Python specific notes:
The object exposes a writable attribute 'disp'. This is the setter.

dup

Signature: *[const]* new ICplxTrans ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

from_dtrans

Signature: *[static]* new ICplxTrans ptr **from_dtrans** (const DCplxTrans trans, double dbu = 1)

Description: Creates an integer coordinate transformation from another coordinate flavour

Use of this method is deprecated. Use new instead

The 'dbu' argument is used to transform the input space and output space from floating-point units to integer units and vice versa. Formally, the ICplxTrans transformation is initialized with 'to_dbu * trans * from_dbu' where 'from_dbu' is the transformation into micrometer space, or more precisely 'CplxTrans(mag=dbu)' and 'to_dbu' is the transformation into DBU space, or more precisely 'VCplxTrans(mag=1/dbu)'.

This constructor has been introduced in version 0.25. The 'dbu' argument has been added in version 0.29.

Python specific notes:
This method is the default initializer of the object.

from_s

Signature: *[static]* new ICplxTrans ptr **from_s** (string s)

Description: Creates an object from a string

Creates the object from a string representation (as returned by to_s)

This method has been added in version 0.23.

from_trans

Signature: *[static]* new ICplxTrans ptr **from_trans** (const CplxTrans trans, double dbu = 1)

Description: Creates an integer coordinate transformation from another coordinate flavour

Use of this method is deprecated. Use new instead

The 'dbu' argument is used to transform the output space from floating-point units to integer units. Formally, the CplxTrans transformation is initialized with 'to_dbu * trans' where 'to_dbu' is the transformation into DBU space, or more precisely 'VCplxTrans(mag=1/dbu)'.

This constructor has been introduced in version 0.25. The 'dbu' argument has been added in version 0.29.

Python specific notes:
This method is the default initializer of the object.

hash

Signature: *[const]* unsigned long **hash**

Description: Computes a hash value

Returns a hash value for the given transformation. This method enables transformations as hash keys.

This method has been introduced in version 0.25.

Python specific notes:
This method is also available as 'hash(object)'.

invert

Signature: ICplxTrans **invert**

Description: Inverts the transformation (in place)

Returns: The inverted transformation

Inverts the transformation and replaces this transformation by its inverted one.

inverted

Signature: *[const]* ICplxTrans **inverted**

Description: Returns the inverted transformation

Returns: The inverted transformation

Returns the inverted transformation. This method does not modify the transformation.

is_complex?

Signature: *[const]* bool **is_complex?**

Description: Returns true if the transformation is a complex one

If this predicate is false, the transformation can safely be converted to a simple transformation. Otherwise, this conversion will be lossy. The predicate value is equivalent to 'is_mag || !is_ortho'.

This method has been introduced in version 0.27.5.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_mag?

Signature: *[const]* bool **is_mag?**

Description: Tests, if the transformation is a magnifying one

This is the recommended test for checking if the transformation represents a magnification.

is_mirror?

Signature: *[const]* bool **is_mirror?**

Description: Gets the mirror flag

If this property is true, the transformation is composed of a mirroring at the x-axis followed by a rotation by the angle given by the angle property.

Python specific notes:
The object exposes a readable attribute 'mirror'. This is the getter.

is_ortho?

Signature: *[const]* bool **is_ortho?**

Description: Tests, if the transformation is an orthogonal transformation

If the rotation is by a multiple of 90 degree, this method will return true.

is_unity?

Signature: *[const]* bool **is_unity?**

Description: Tests, whether this is a unit transformation

mag

Signature: *[const]* double **mag**

Description: Gets the magnification

Python specific notes:
The object exposes a readable attribute 'mag'. This is the getter.

mag=

Signature: void **mag=** (double m)

Description: Sets the magnification

m: The new magnification

Python specific notes:
The object exposes a writable attribute 'mag'. This is the setter.

mirror=

Signature: void **mirror=** (bool m)

Description: Sets the mirror flag

m: The new mirror flag

"mirroring" describes a reflection at the x-axis which is included in the transformation prior to rotation.

Python specific notes:
The object exposes a writable attribute 'mirror'. This is the setter.

new

(1) Signature: *[static]* new ICplxTrans ptr **new** (const DCplxTrans trans, double dbu = 1)

Description: Creates an integer coordinate transformation from another coordinate flavour

The 'dbu' argument is used to transform the input space and output space from floating-point units to integer units and vice versa. Formally, the ICplxTrans transformation is initialized with 'to_dbu * trans * from_dbu' where 'from_dbu' is the transformation into micrometer space, or more

precisely 'CplxTrans(mag=dbu)' and 'to_dbu' is the transformation into DBU space, or more precisely 'VCplxTrans(mag=1/dbu)'.

This constructor has been introduced in version 0.25. The 'dbu' argument has been added in version 0.29.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new ICplxTrans ptr **new** (const CplxTrans trans, double dbu = 1)

Description: Creates an integer coordinate transformation from another coordinate flavour

The 'dbu' argument is used to transform the output space from floating-point units to integer units. Formally, the CplxTrans transformation is initialized with 'to_dbu * trans' where 'to_dbu' is the transformation into DBU space, or more precisely 'VCplxTrans(mag=1/dbu)'.

This constructor has been introduced in version 0.25. The 'dbu' argument has been added in version 0.29.

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new ICplxTrans ptr **new** (const VCplxTrans trans, double dbu = 1)

Description: Creates an integer coordinate transformation from another coordinate flavour

The 'dbu' argument is used to transform the input space from floating-point units to integer units. Formally, the CplxTrans transformation is initialized with 'trans * from_dbu' where 'from_dbu' is the transformation into micrometer space, or more precisely 'CplxTrans(mag=dbu)'.

This constructor has been introduced in version 0.25. The 'dbu' argument has been added in version 0.29.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new ICplxTrans ptr **new**

Description: Creates a unit transformation

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new ICplxTrans ptr **new** (const ICplxTrans c, double mag = 1, const Vector u = 0,0)

Description: Creates a transformation from another transformation plus a magnification and displacement

c:	The original transformation
u:	The Additional displacement

Creates a new transformation from a existing transformation. This constructor is provided for creating duplicates and backward compatibility since the constants are transformations now. It will copy the original transformation and add the given displacement.

This variant has been introduced in version 0.25.

Python specific notes:
This method is the default initializer of the object.

(6) Signature: *[static]* new ICplxTrans ptr **new** (const ICplxTrans c, double mag = 1, int x = 0, int y = 0)

Description: Creates a transformation from another transformation plus a magnification and displacement

c:	The original transformation
x:	The Additional displacement (x)
y:	The Additional displacement (y)

Creates a new transformation from a existing transformation. This constructor is provided for creating duplicates and backward compatibility since the constants are transformations now. It will copy the original transformation and add the given displacement.

This variant has been introduced in version 0.25.

Python specific notes:
This method is the default initializer of the object.

(7) Signature: *[static]* new ICplxTrans ptr **new** (int x, int y)

Description: Creates a transformation from a x and y displacement

x:	The x displacement
y:	The y displacement

This constructor will create a transformation with the specified displacement but no rotation.

Python specific notes:
This method is the default initializer of the object.

(8) Signature: *[static]* new ICplxTrans ptr **new** (const Trans t, double mag = 1)

Description: Creates a transformation from a simple transformation and a magnification

Creates a magnifying transformation from a simple transformation and a magnification.

Python specific notes:
This method is the default initializer of the object.

(9) Signature: *[static]* new ICplxTrans ptr **new** (const Vector u)

Description: Creates a transformation from a displacement

Creates a transformation with a displacement only.

This method has been added in version 0.25.

Python specific notes:
This method is the default initializer of the object.

(10) Signature: *[static]* new ICplxTrans ptr **new** (double mag = 1, double rot = 0, bool mirrx = false, const Vector u = 0,0)

Description: Creates a transformation using magnification, angle, mirror flag and displacement

mag:	The magnification
rot:	The rotation angle in units of degree
mirrx:	True, if mirrored at x axis
u:	The displacement

The sequence of operations is: magnification, mirroring at x axis, rotation, application of displacement.

Python specific notes:
This method is the default initializer of the object.

(11) Signature: *[static]* new ICplxTrans ptr **new** (double mag = 1, double rot = 0, bool mirrx = false, int x = 0, int y = 0)

Description: Creates a transformation using magnification, angle, mirror flag and displacement

mag:	The magnification
rot:	The rotation angle in units of degree
mirrx:	True, if mirrored at x axis
x:	The x displacement
y:	The y displacement

The sequence of operations is: magnification, mirroring at x axis, rotation, application of displacement.

Python specific notes:
This method is the default initializer of the object.

rot

Signature: *[const]* int **rot**

Description: Returns the respective simple transformation equivalent rotation code if possible

If this transformation is orthogonal (is_ortho () == true), then this method will return the corresponding fixpoint transformation, not taking into account magnification and displacement. If the transformation is not orthogonal, the result reflects the quadrant the rotation goes into.

s_trans

Signature: *[const]* Trans **s_trans**

Description: Extracts the simple transformation part

The simple transformation part does not reflect magnification or arbitrary angles. Rotation angles are rounded down to multiples of 90 degree. Magnification is fixed to 1.0.

to_itrans

Signature: *[const]* DCplxTrans **to_itrans** (double dbu = 1)

Description: Converts the transformation to another transformation with floating-point input and output coordinates

Use of this method is deprecated

The database unit can be specified to translate the integer coordinate displacement in database units to a floating-point displacement in micron units. The displacement's' coordinates will be multiplied with the database unit.

This method is redundant with the conversion constructors and is ill-named. Instead of 'to_itrans' use the conversion constructor:

```
dtrans = RBA::DCplxTrans::new(itrans, dbu)
```

This method has been introduced in version 0.25 and was deprecated in version 0.29.

to_s

Signature: *[const]* string **to_s** (bool lazy = false, double dbu = 0)

Description: String conversion

If 'lazy' is true, some parts are omitted when not required. If a DBU is given, the output units will be micrometers.

The lazy and DBU arguments have been added in version 0.27.6.

Python specific notes:
This method is also available as 'str(object)'.

to_trans

Signature: *[const]* VCplxTrans **to_trans** (double dbu = 1)

Description: Converts the transformation to another transformation with floating-point input coordinates

Use of this method is deprecated

This method is redundant with the conversion constructors and is ill-named. Instead of 'to_trans' use the conversion constructor:

```
vtrans = RBA::VCplxTrans::new(itrans, dbu)
```

This method has been introduced in version 0.25 and was deprecated in version 0.29.

to_vtrans

Signature: *[const]* CplxTrans **to_vtrans** (double dbu = 1)

Description: Converts the transformation to another transformation with floating-point output coordinates

Use of this method is deprecated

The database unit can be specified to translate the integer coordinate displacement in database units to a floating-point displacement in micron units. The displacement's' coordinates will be multiplied with the database unit.

This method is redundant with the conversion constructors and is ill-named. Instead of 'to_vtrans' use the conversion constructor:

```
trans = RBA::CplxTrans::new(itrans, dbu)
```

This method has been introduced in version 0.25 and was deprecated in version 0.29.

trans

(1) Signature: *[const]* Point **trans** (const Point p)

Description: Transforms a point

p:	The point to transform
Returns:	The transformed point

The "trans" method or the * operator transforms the given point. q = t(p)

The * operator has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(2) Signature: *[const]* Vector **trans** (const Vector p)

Description: Transforms a vector

v:	The vector to transform
Returns:	The transformed vector

The "trans" method or the * operator transforms the given vector. w = t(v)

Vector transformation has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(3) Signature: *[const]* Box **trans** (const Box box)

Description: Transforms a box

box:	The box to transform
Returns:	The transformed box

't*box' or 't.trans(box)' is equivalent to box.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(4) Signature: *[const]* Edge **trans** (const Edge edge)

Description: Transforms an edge

edge:	The edge to transform
Returns:	The transformed edge

't*edge' or 't.trans(edge)' is equivalent to edge.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(5) Signature: *[const]* Polygon **trans** (const Polygon polygon)

Description: Transforms a polygon

polygon:	The polygon to transform
Returns:	The transformed polygon

't*polygon' or 't.trans(polygon)' is equivalent to polygon.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(6) Signature: *[const]* Path **trans** (const Path path)

Description: Transforms a path

path:	The path to transform
Returns:	The transformed path

't*path' or 't.trans(path)' is equivalent to path.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(7) Signature: *[const]* Text **trans** (const Text text)

Description: Transforms a text

text:	The text to transform
Returns:	The transformed text

't*text' or 't.trans(text)' is equivalent to text.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

4.110. API reference - Class VCplxTrans

Notation used in Ruby API documentation

Module: db

Description: A complex transformation

A complex transformation provides magnification, mirroring at the x-axis, rotation by an arbitrary angle and a displacement. This is also the order, the operations are applied. This version can transform floating point coordinate objects into integer coordinate objects, which may involve rounding and can be inexact.

Complex transformations are extensions of the simple transformation classes (Trans in that case) and behave similar.

Transformations can be used to transform points or other objects. Transformations can be combined with the '*' operator to form the transformation which is equivalent to applying the second and then the first. Here is some code:

```
# Create a transformation that applies a magnification of 1.5, a rotation by 90 degree
# and displacement of 10 in x and 20 units in y direction:
t = RBA::VCplxTrans::new(1.5, 90, false, 10, 20)
t.to_s            # r90 *1.5 10,20
# compute the inverse:
t.inverted.to_s   # r270 *0.666666667 -13,7
# Combine with another displacement (applied after that):
(RBA::VCplxTrans::new(5, 5) * t).to_s     # r90 *1.5 15,25
# Transform a point:
t.trans(RBA::DPoint::new(100, 200)).to_s  # -290,170
```

The VCplxTrans type is the inverse transformation of the CplxTrans transformation and vice versa.Transformations of VCplxTrans type can be concatenated (operator *) with either itself or with transformations of compatible input or output type. This means, the operator VCplxTrans * CplxTrans is allowed (output types of CplxTrans and input of VCplxTrans are identical) while VCplxTrans * ICplxTrans is not.

This class has been introduced in version 0.25.

See The Database API for more details about the database objects.

Public constructors

new VCplxTrans ptr	**new**	(const DCplxTrans trans, double dbu = 1)	Creates a floating-point to integer coordinate transformation from another coordinate flavour
new VCplxTrans ptr	**new**	(const CplxTrans trans, double dbu = 1)	Creates a floating-point to integer coordinate transformation from another coordinate flavour
new VCplxTrans ptr	**new**	(const ICplxTrans trans, double dbu = 1)	Creates a floating-point to integer coordinate transformation from another coordinate flavour
new VCplxTrans ptr	**new**		Creates a unit transformation
new VCplxTrans ptr	**new**	(const VCplxTrans c, double mag = 1, const Vector u = 0,0)	Creates a transformation from another transformation plus a magnification and displacement
new VCplxTrans ptr	**new**	(const VCplxTrans c, double mag = 1, int x = 0, int y = 0)	Creates a transformation from another transformation plus a magnification and displacement
new VCplxTrans ptr	**new**	(int x, int y)	Creates a transformation from a x and y displacement

new VCplxTrans ptr	new	(const DTrans t, double mag = 1)	Creates a transformation from a simple transformation and a magnification
new VCplxTrans ptr	new	(const Vector u)	Creates a transformation from a displacement
new VCplxTrans ptr	new	(double mag = 1, double rot = 0, bool mirrx = false, const Vector u = 0,0)	Creates a transformation using magnification, angle, mirror flag and displacement
new VCplxTrans ptr	new	(double mag = 1, double rot = 0, bool mirrx = false, int x = 0, int y = 0)	Creates a transformation using magnification, angle, mirror flag and displacement

Public methods

[const]	bool	!=	(const VCplxTrans other)	Tests for inequality
[const]	VCplxTrans	*	(const DCplxTrans t)	Multiplication (concatenation) of transformations
[const]	ICplxTrans	*	(const CplxTrans t)	Multiplication (concatenation) of transformations
[const]	unsigned int	*	(double d)	Transforms a distance
[const]	Point	*	(const DPoint p)	Transforms a point
[const]	Vector	*	(const DVector p)	Transforms a vector
[const]	Box	*	(const DBox box)	Transforms a box
[const]	Edge	*	(const DEdge edge)	Transforms an edge
[const]	Polygon	*	(const DPolygon polygon)	Transforms a polygon
[const]	Path	*	(const DPath path)	Transforms a path
[const]	Text	*	(const DText text)	Transforms a text
[const]	VCplxTrans	*	(const VCplxTrans t)	Returns the concatenated transformation
[const]	bool	<	(const VCplxTrans other)	Provides a 'less' criterion for sorting
[const]	bool	==	(const VCplxTrans other)	Tests for equality
	void	_create		Ensures the C++ object is created
	void	_destroy		Explicitly destroys the object

[const]	bool	_destroyed?		Returns a value indicating whether the object was already destroyed
[const]	bool	_is_const_object?		Returns a value indicating whether the reference is a const reference
	void	_manage		Marks the object as managed by the script side.
	void	_unmanage		Marks the object as no longer owned by the script side.
[const]	double	angle		Gets the angle
	void	angle=	(double a)	Sets the angle
	void	assign	(const VCplxTrans other)	Assigns another object to self
[const]	unsigned int	ctrans	(double d)	Transforms a distance
[const]	Vector	disp		Gets the displacement
	void	disp=	(const Vector u)	Sets the displacement
[const]	new VCplxTrans ptr	dup		Creates a copy of self
[const]	unsigned long	hash		Computes a hash value
	VCplxTrans	invert		Inverts the transformation (in place)
[const]	CplxTrans	inverted		Returns the inverted transformation
[const]	bool	is_complex?		Returns true if the transformation is a complex one
[const]	bool	is_mag?		Tests, if the transformation is a magnifying one
[const]	bool	is_mirror?		Gets the mirror flag
[const]	bool	is_ortho?		Tests, if the transformation is an orthogonal transformation
[const]	bool	is_unity?		Tests, whether this is a unit transformation
[const]	double	mag		Gets the magnification
	void	mag=	(double m)	Sets the magnification
	void	mirror=	(bool m)	Sets the mirror flag
[const]	int	rot		Returns the respective simple transformation equivalent rotation code if possible
[const]	DTrans	s_trans		Extracts the simple transformation part

[const]	string	**to_s**	(bool lazy = false, double dbu = 0)	String conversion
[const]	Point	**trans**	(const DPoint p)	Transforms a point
[const]	Vector	**trans**	(const DVector p)	Transforms a vector
[const]	Box	**trans**	(const DBox box)	Transforms a box
[const]	Edge	**trans**	(const DEdge edge)	Transforms an edge
[const]	Polygon	**trans**	(const DPolygon polygon)	Transforms a polygon
[const]	Path	**trans**	(const DPath path)	Transforms a path
[const]	Text	**trans**	(const DText text)	Transforms a text

Public static methods and constants

VCplxTrans	**M0**		A constant giving "mirrored at the x-axis" transformation
VCplxTrans	**M135**		A constant giving "mirrored at the 135 degree axis" transformation
VCplxTrans	**M45**		A constant giving "mirrored at the 45 degree axis" transformation
VCplxTrans	**M90**		A constant giving "mirrored at the y (90 degree) axis" transformation
VCplxTrans	**R0**		A constant giving "unrotated" (unit) transformation
VCplxTrans	**R180**		A constant giving "rotated by 180 degree counterclockwise" transformation
VCplxTrans	**R270**		A constant giving "rotated by 270 degree counterclockwise" transformation
VCplxTrans	**R90**		A constant giving "rotated by 90 degree counterclockwise" transformation
new VCplxTrans ptr	**from_s**	(string s)	Creates an object from a string

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**		Use of this method is deprecated. Use _create instead
	void	**destroy**		Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**		Use of this method is deprecated. Use _destroyed? instead

[const]	bool	**is_const_object?**		Use of this method is deprecated. Use _is_const_object? instead
[const]	DCplxTrans	**to_itrans**	(double dbu = 1)	Use of this method is deprecated
[const]	ICplxTrans	**to_trans**	(double arg1)	Use of this method is deprecated
[const]	CplxTrans	**to_vtrans**	(double dbu = 1)	Use of this method is deprecated

Detailed description

!=

Signature: *[const]* bool **!=** (const VCplxTrans other)

Description: Tests for inequality

*****

(1) Signature: *[const]* VCplxTrans ***** (const DCplxTrans t)

Description: Multiplication (concatenation) of transformations

t: The transformation to apply before

Returns: The modified transformation

The * operator returns self*t ("t is applied before this transformation").

(2) Signature: *[const]* ICplxTrans ***** (const CplxTrans t)

Description: Multiplication (concatenation) of transformations

t: The transformation to apply before

Returns: The modified transformation

The * operator returns self*t ("t is applied before this transformation").

(3) Signature: *[const]* unsigned int ***** (double d)

Description: Transforms a distance

d: The distance to transform

Returns: The transformed distance

The "ctrans" method transforms the given distance. e = t(d). For the simple transformations, there is no magnification and no modification of the distance therefore.

The product '*' has been added as a synonym in version 0.28.

Python specific notes:
This method also implements '__rmul__'.

(4) Signature: *[const]* Point ***** (const DPoint p)

Description: Transforms a point

p: The point to transform

Returns: The transformed point

The "trans" method or the * operator transforms the given point. q = t(p)

The * operator has been introduced in version 0.25.

Python specific notes:

This method also implements '__rmul__'.

(5) Signature: *[const]* Vector ***** (const DVector p)

Description: Transforms a vector

v:	The vector to transform
Returns:	The transformed vector

The "trans" method or the * operator transforms the given vector. w = t(v)

Vector transformation has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(6) Signature: *[const]* Box ***** (const DBox box)

Description: Transforms a box

box:	The box to transform
Returns:	The transformed box

't*box' or 't.trans(box)' is equivalent to box.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(7) Signature: *[const]* Edge ***** (const DEdge edge)

Description: Transforms an edge

edge:	The edge to transform
Returns:	The transformed edge

't*edge' or 't.trans(edge)' is equivalent to edge.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(8) Signature: *[const]* Polygon ***** (const DPolygon polygon)

Description: Transforms a polygon

polygon:	The polygon to transform
Returns:	The transformed polygon

't*polygon' or 't.trans(polygon)' is equivalent to polygon.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(9) Signature: *[const]* Path ***** (const DPath path)

Description: Transforms a path

path:	The path to transform
Returns:	The transformed path

't*path' or 't.trans(path)' is equivalent to path.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(10) Signature: *[const]* Text ***** (const DText text)

Description: Transforms a text

text:	The text to transform
Returns:	The transformed text

't*text' or 't.trans(text)' is equivalent to text.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(11) Signature: *[const]* VCplxTrans ***** (const VCplxTrans t)

Description: Returns the concatenated transformation

t:	The transformation to apply before
Returns:	The modified transformation

The * operator returns self*t ("t is applied before this transformation").

<

Signature: *[const]* bool **<** (const VCplxTrans other)

Description: Provides a 'less' criterion for sorting

This method is provided to implement a sorting order. The definition of 'less' is opaque and might change in future versions.

==

Signature: *[const]* bool **==** (const VCplxTrans other)

Description: Tests for equality

M0

Signature: *[static]* VCplxTrans **M0**

Description: A constant giving "mirrored at the x-axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M0'. This is the getter.

M135

Signature: *[static]* VCplxTrans **M135**

Description: A constant giving "mirrored at the 135 degree axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M135'. This is the getter.

M45

Signature: *[static]* VCplxTrans **M45**

Description: A constant giving "mirrored at the 45 degree axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M45'. This is the getter.

M90

Signature: *[static]* VCplxTrans **M90**

Description: A constant giving "mirrored at the y (90 degree) axis" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'M90'. This is the getter.

R0

Signature: *[static]* VCplxTrans **R0**

Description: A constant giving "unrotated" (unit) transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R0'. This is the getter.

R180

Signature: *[static]* VCplxTrans **R180**

Description: A constant giving "rotated by 180 degree counterclockwise" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R180'. This is the getter.

R270

Signature: *[static]* VCplxTrans **R270**

Description: A constant giving "rotated by 270 degree counterclockwise" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R270'. This is the getter.

R90

Signature: *[static]* VCplxTrans **R90**

Description: A constant giving "rotated by 90 degree counterclockwise" transformation

The previous integer constant has been turned into a transformation in version 0.25.

Python specific notes:
The object exposes a readable attribute 'R90'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

angle

Signature: *[const]* double **angle**

Description: Gets the angle

Returns: The rotation angle this transformation provides in degree units (0..360 deg).

Note that the simple transformation returns the angle in units of 90 degree. Hence for a simple trans (i.e. Trans), a rotation angle of 180 degree delivers a value of 2 for the angle attribute. The complex transformation, supporting any rotation angle returns the angle in degree.

Python specific notes:
The object exposes a readable attribute 'angle'. This is the getter.

angle=

Signature: void **angle=** (double a)

Description: Sets the angle

a: The new angle

See angle for a description of that attribute.

Python specific notes:
The object exposes a writable attribute 'angle'. This is the setter.

assign

Signature: void **assign** (const VCplxTrans other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

ctrans

Signature: *[const]* unsigned int **ctrans** (double d)

Description: Transforms a distance

d: The distance to transform

Returns: The transformed distance

The "ctrans" method transforms the given distance. e = t(d). For the simple transformations, there is no magnification and no modification of the distance therefore.

The product '*' has been added as a synonym in version 0.28.

Python specific notes:
This method also implements '__rmul__'.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

disp

Signature: *[const]* Vector **disp**

Description: Gets the displacement

Python specific notes:
The object exposes a readable attribute 'disp'. This is the getter.

disp=

Signature: void **disp=** (const Vector u)

Description: Sets the displacement

u: The new displacement

Python specific notes:
The object exposes a writable attribute 'disp'. This is the setter.

dup

Signature: *[const]* new VCplxTrans ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

from_s

Signature: *[static]* new VCplxTrans ptr **from_s** (string s)

Description: Creates an object from a string

Creates the object from a string representation (as returned by to_s)

This method has been added in version 0.23.

hash

Signature: *[const]* unsigned long **hash**

Description: Computes a hash value

Returns a hash value for the given transformation. This method enables transformations as hash keys.

This method has been introduced in version 0.25.

Python specific notes:
This method is also available as 'hash(object)'.

invert

Signature: VCplxTrans **invert**

Description: Inverts the transformation (in place)

Returns: The inverted transformation

Inverts the transformation and replaces this transformation by its inverted one.

inverted

Signature: *[const]* CplxTrans **inverted**

Description: Returns the inverted transformation

Returns: The inverted transformation

Returns the inverted transformation. This method does not modify the transformation.

is_complex?

Signature: *[const]* bool **is_complex?**

Description: Returns true if the transformation is a complex one

If this predicate is false, the transformation can safely be converted to a simple transformation. Otherwise, this conversion will be lossy. The predicate value is equivalent to 'is_mag || !is_ortho'.

This method has been introduced in version 0.27.5.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_mag?

Signature: *[const]* bool **is_mag?**

Description: Tests, if the transformation is a magnifying one

This is the recommended test for checking if the transformation represents a magnification.

is_mirror?

Signature: *[const]* bool **is_mirror?**

Description: Gets the mirror flag

If this property is true, the transformation is composed of a mirroring at the x-axis followed by a rotation by the angle given by the angle property.

Python specific notes:
The object exposes a readable attribute 'mirror'. This is the getter.

is_ortho?

Signature: *[const]* bool **is_ortho?**

Description: Tests, if the transformation is an orthogonal transformation

If the rotation is by a multiple of 90 degree, this method will return true.

is_unity?

Signature: *[const]* bool **is_unity?**

Description: Tests, whether this is a unit transformation

mag

Signature: *[const]* double **mag**

Description: Gets the magnification

Python specific notes:
The object exposes a readable attribute 'mag'. This is the getter.

mag=

Signature: void **mag=** (double m)

Description: Sets the magnification

m: The new magnification

Python specific notes:
The object exposes a writable attribute 'mag'. This is the setter.

mirror=

Signature: void **mirror=** (bool m)

Description: Sets the mirror flag

m: The new mirror flag

"mirroring" describes a reflection at the x-axis which is included in the transformation prior to rotation.

Python specific notes:
The object exposes a writable attribute 'mirror'. This is the setter.

new

(1) Signature: *[static]* new VCplxTrans ptr **new** (const DCplxTrans trans, double dbu = 1)

Description: Creates a floating-point to integer coordinate transformation from another coordinate flavour

The 'dbu' argument is used to transform the output space from floating-point units to integer units. Formally, the VCplxTrans transformation is initialized with 'to_dbu * trans' where 'to_dbu' is the transformation into DBU space, or more precisely 'VCplxTrans(mag=1/dbu)'.

The 'dbu' argument has been added in version 0.29.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new VCplxTrans ptr **new** (const CplxTrans trans, double dbu = 1)

Description: Creates a floating-point to integer coordinate transformation from another coordinate flavour

The 'dbu' argument is used to transform the input and output space from floating-point units to integer units and vice versa. Formally, the VCplxTrans transformation is initialized with 'to_dbu * trans * to_dbu' where 'to_dbu' is the transformation into DBU space, or more precisely 'VCplxTrans(mag=1/dbu)'.

The 'dbu' argument has been added in version 0.29.

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new VCplxTrans ptr **new** (const ICplxTrans trans, double dbu = 1)

Description: Creates a floating-point to integer coordinate transformation from another coordinate flavour

The 'dbu' argument is used to transform the input and output space from floating-point units to integer units and vice versa. Formally, the VCplxTrans transformation is initialized with 'trans * to_dbu' where 'to_dbu' is the transformation into DBU space, or more precisely 'VCplxTrans(mag=1/dbu)'.

The 'dbu' argument has been added in version 0.29.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new VCplxTrans ptr **new**

Description: Creates a unit transformation

Python specific notes:
This method is the default initializer of the object.

(5) Signature: *[static]* new VCplxTrans ptr **new** (const VCplxTrans c, double mag = 1, const Vector u = 0,0)

Description: Creates a transformation from another transformation plus a magnification and displacement

c:	The original transformation
u:	The Additional displacement

Creates a new transformation from a existing transformation. This constructor is provided for creating duplicates and backward compatibility since the constants are transformations now. It will copy the original transformation and add the given displacement.

This variant has been introduced in version 0.25.

Python specific notes:
This method is the default initializer of the object.

(6) Signature: *[static]* new VCplxTrans ptr **new** (const VCplxTrans c, double mag = 1, int x = 0, int y = 0)

Description: Creates a transformation from another transformation plus a magnification and displacement

c:	The original transformation
x:	The Additional displacement (x)
y:	The Additional displacement (y)

Creates a new transformation from a existing transformation. This constructor is provided for creating duplicates and backward compatibility since the constants are transformations now. It will copy the original transformation and add the given displacement.

This variant has been introduced in version 0.25.

Python specific notes:
This method is the default initializer of the object.

(7) Signature: *[static]* new VCplxTrans ptr **new** (int x, int y)

Description: Creates a transformation from a x and y displacement

x:	The x displacement
y:	The y displacement

This constructor will create a transformation with the specified displacement but no rotation.

Python specific notes:
This method is the default initializer of the object.

(8) Signature: *[static]* new VCplxTrans ptr **new** (const DTrans t, double mag = 1)

Description: Creates a transformation from a simple transformation and a magnification

Creates a magnifying transformation from a simple transformation and a magnification.

Python specific notes:
This method is the default initializer of the object.

(9) Signature: *[static]* new VCplxTrans ptr **new** (const Vector u)

Description: Creates a transformation from a displacement

Creates a transformation with a displacement only.

This method has been added in version 0.25.

Python specific notes:
This method is the default initializer of the object.

(10) Signature: *[static]* new VCplxTrans ptr **new** (double mag = 1, double rot = 0, bool mirrx = false, const Vector u = 0,0)

Description: Creates a transformation using magnification, angle, mirror flag and displacement

mag:	The magnification
rot:	The rotation angle in units of degree
mirrx:	True, if mirrored at x axis
u:	The displacement

The sequence of operations is: magnification, mirroring at x axis, rotation, application of displacement.

Python specific notes:
This method is the default initializer of the object.

(11) Signature: *[static]* new VCplxTrans ptr **new** (double mag = 1, double rot = 0, bool mirrx = false, int x = 0, int y = 0)

Description: Creates a transformation using magnification, angle, mirror flag and displacement

mag:	The magnification
rot:	The rotation angle in units of degree
mirrx:	True, if mirrored at x axis
x:	The x displacement
y:	The y displacement

The sequence of operations is: magnification, mirroring at x axis, rotation, application of displacement.

Python specific notes:
This method is the default initializer of the object.

rot

Signature: *[const]* int **rot**

Description: Returns the respective simple transformation equivalent rotation code if possible

If this transformation is orthogonal (is_ortho () == true), then this method will return the corresponding fixpoint transformation, not taking into account magnification and displacement. If the transformation is not orthogonal, the result reflects the quadrant the rotation goes into.

s_trans

Signature: *[const]* DTrans **s_trans**

Description: Extracts the simple transformation part

The simple transformation part does not reflect magnification or arbitrary angles. Rotation angles are rounded down to multiples of 90 degree. Magnification is fixed to 1.0.

to_itrans

Signature: *[const]* DCplxTrans **to_itrans** (double dbu = 1)

Description: Converts the transformation to another transformation with floating-point output coordinates

Use of this method is deprecated

The database unit can be specified to translate the integer coordinate displacement in database units to a floating-point displacement in micron units. The displacement's' coordinates will be multiplied with the database unit.

This method is redundant with the conversion constructors and is ill-named. Instead of 'to_itrans' use the conversion constructor:

```
dtrans = RBA::DCplxTrans::new(vtrans, dbu)
```

This method has been deprecated in version 0.29.

to_s

Signature: *[const]* string **to_s** (bool lazy = false, double dbu = 0)

Description: String conversion

If 'lazy' is true, some parts are omitted when not required. If a DBU is given, the output units will be micrometers.

The lazy and DBU arguments have been added in version 0.27.6.

Python specific notes:
This method is also available as 'str(object)'.

to_trans

Signature: *[const]* ICplxTrans **to_trans** (double arg1)

Description: Converts the transformation to another transformation with integer input coordinates

Use of this method is deprecated

This method is redundant with the conversion constructors and is ill-named. Instead of 'to_trans' use the conversion constructor:

```
itrans = RBA::ICplxTrans::new(vtrans, dbu)
```

This method has been deprecated in version 0.29.

to_vtrans

Signature: *[const]* CplxTrans **to_vtrans** (double dbu = 1)

Description: Converts the transformation to another transformation with integer input and floating-point output coordinates

Use of this method is deprecated

The database unit can be specified to translate the integer coordinate displacement in database units to an floating-point displacement in micron units. The displacement's' coordinates will be multiplied with the database unit.

This method is redundant with the conversion constructors and is ill-named. Instead of 'to_vtrans' use the conversion constructor:

```
trans = RBA::CplxTrans::new(vtrans, dbu)
```

This method has been deprecated in version 0.29.

trans

(1) Signature: *[const]* Point **trans** (const DPoint p)

Description: Transforms a point

p:	The point to transform
Returns:	The transformed point

The "trans" method or the * operator transforms the given point. q = t(p)

The * operator has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(2) Signature: *[const]* Vector **trans** (const DVector p)

Description: Transforms a vector

v:	The vector to transform
Returns:	The transformed vector

The "trans" method or the * operator transforms the given vector. w = t(v)

Vector transformation has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(3) Signature: *[const]* Box **trans** (const DBox box)

Description: Transforms a box

box:	The box to transform
Returns:	The transformed box

't*box' or 't.trans(box)' is equivalent to box.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(4) Signature: *[const]* Edge **trans** (const DEdge edge)

Description: Transforms an edge

edge:	The edge to transform
Returns:	The transformed edge

't*edge' or 't.trans(edge)' is equivalent to edge.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(5) Signature: *[const]* Polygon **trans** (const DPolygon polygon)

Description: Transforms a polygon

polygon:	The polygon to transform

Returns: The transformed polygon

't*polygon' or 't.trans(polygon)' is equivalent to polygon.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(6) Signature: *[const]* Path **trans** (const DPath path)

Description: Transforms a path

path: The path to transform

Returns: The transformed path

't*path' or 't.trans(path)' is equivalent to path.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

(7) Signature: *[const]* Text **trans** (const DText text)

Description: Transforms a text

text: The text to transform

Returns: The transformed text

't*text' or 't.trans(text)' is equivalent to text.transformed(t).

This convenience method has been introduced in version 0.25.

Python specific notes:
This method also implements '__rmul__'.

4.111. API reference - Class Utils

Notation used in Ruby API documentation

Module: db

Description: This namespace provides a collection of utility functions

This class has been introduced in version 0.27.

Public constructors

new Utils ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const Utils other)	Assigns another object to self
[const]	new Utils ptr	**dup**		Creates a copy of self

Public static methods and constants

	DPoint[]	**spline_interpolation**	(DPoint[] control_points, double[] weights, int degree, double[] knots, double relative_accuracy, double absolute_accuracy)	This function computes the Spline curve for a given set of control points (point, weight), degree and knots.
	Point[]	**spline_interpolation**	(Point[] control_points, double[] weights, int degree, double[] knots, double relative_accuracy, double absolute_accuracy)	This function computes the Spline curve for a given set of control points (point, weight), degree and knots.
	DPoint[]	**spline_interpolation**	(DPoint[] control_points, int degree, double[] knots, double relative_accuracy,	This function computes the Spline curve for a given set of control points (point, weight), degree and knots.

		double absolute_accuracy)	
Point[]	spline_interpolation	(Point[] control_points, int degree, double[] knots, double relative_accuracy, double absolute_accuracy)	This function computes the Spline curve for a given set of control points (point, weight), degree and knots.

Deprecated methods (protected, public, static, non-static and constructors)

	void	create	Use of this method is deprecated. Use _create instead
	void	destroy	Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	is_const_object?	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void _**create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void _**destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool _**destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool _**is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void _**manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

	Usually it's not required to call this method. It has been introduced in version 0.24.
_unmanage	**Signature**: void **_unmanage** **Description**: Marks the object as no longer owned by the script side. Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.
assign	**Signature**: void **assign** (const Utils other) **Description**: Assigns another object to self
create	**Signature**: void **create** **Description**: Ensures the C++ object is created Use of this method is deprecated. Use _create instead Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
destroy	**Signature**: void **destroy** **Description**: Explicitly destroys the object Use of this method is deprecated. Use _destroy instead Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
destroyed?	**Signature**: *[const]* bool **destroyed?** **Description**: Returns a value indicating whether the object was already destroyed Use of this method is deprecated. Use _destroyed? instead This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
dup	**Signature**: *[const]* new Utils ptr **dup** **Description**: Creates a copy of self **Python specific notes:** This method also implements '__copy__' and '__deepcopy__'.
is_const_object?	**Signature**: *[const]* bool **is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new Utils ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

spline_interpolation

(1) Signature: *[static]* DPoint[] **spline_interpolation** (DPoint[] control_points, double[] weights, int degree, double[] knots, double relative_accuracy, double absolute_accuracy)

Description: This function computes the Spline curve for a given set of control points (point, weight), degree and knots.

The knot vector needs to be padded and its size must fulfill the condition:

```
knots.size == control_points.size + degree + 1
```

The accuracy parameters allow tuning the resolution of the curve to target a specific approximation quality. "relative_accuracy" gives the accuracy relative to the local curvature radius, "absolute" accuracy gives the absolute accuracy. "accuracy" is the allowed deviation of polygon approximation from the ideal curve. The computed curve should meet at least one of the accuracy criteria. Setting both limits to a very small value will result in long run times and a large number of points returned.

This function supports both rational splines (NURBS) and non-rational splines. The latter use weights of 1.0 for each point.

The return value is a list of points forming a path which approximates the spline curve.

(2) Signature: *[static]* Point[] **spline_interpolation** (Point[] control_points, double[] weights, int degree, double[] knots, double relative_accuracy, double absolute_accuracy)

Description: This function computes the Spline curve for a given set of control points (point, weight), degree and knots.

This is the version for integer-coordinate points.

(3) Signature: *[static]* DPoint[] **spline_interpolation** (DPoint[] control_points, int degree, double[] knots, double relative_accuracy, double absolute_accuracy)

Description: This function computes the Spline curve for a given set of control points (point, weight), degree and knots.

This is the version for non-rational splines. It lacks the weight vector.

(4) Signature: *[static]* Point[] **spline_interpolation** (Point[] control_points, int degree, double[] knots, double relative_accuracy, double absolute_accuracy)

Description: This function computes the Spline curve for a given set of control points (point, weight), degree and knots.

This is the version for integer-coordinate points for non-rational splines.

4.112. API reference - Class DVector

Notation used in Ruby API documentation

Module: db

Description: A vector class with double (floating-point) coordinates

A vector is a distance in cartesian, 2 dimensional space. A vector is given by two coordinates (x and y) and represents the distance between two points. Being the distance, transformations act differently on vectors: the displacement is not applied. Vectors are not geometrical objects by itself. But they are frequently used in the database API for various purposes. Other than the integer variant (Vector), points with floating-point coordinates can represent fractions of a database unit or vectors in physical (micron) units.

This class has been introduced in version 0.25.

See The Database API for more details about the database objects.

Public constructors

new DVector ptr	**new**	(const Vector vector)	Creates a floating-point coordinate vector from an integer coordinate vector
new DVector ptr	**new**		Default constructor: creates a null vector with coordinates (0,0)
new DVector ptr	**new**	(const DPoint p)	Default constructor: creates a vector from a point
new DVector ptr	**new**	(double x, double y)	Constructor for a vector from two coordinate values

Public methods

[const]	bool	**!=**	(const DVector v)	Inequality test operator
[const]	DVector	*****	(double f)	Scaling by some factor
[const]	double	*****	(const DVector v)	Computes the scalar product between self and the given vector
	DVector	***=**	(double f)	Scaling by some factor
[const]	DVector	**+**	(const DVector v)	Adds two vectors
[const]	DPoint	**+**	(const DPoint p)	Adds a vector and a point
[const]	DVector	**-**	(const DVector v)	Subtract two vectors
[const]	DVector	**-@**		Compute the negative of a vector
[const]	DVector	***/***	(double d)	Division by some divisor
	DVector	***/=**	(double d)	Division by some divisor
[const]	bool	**<**	(const DVector v)	"less" comparison operator
[const]	bool	**==**	(const DVector v)	Equality test operator
	void	**_create**		Ensures the C++ object is created

	void	_destroy		Explicitly destroys the object
[const]	bool	_destroyed?		Returns a value indicating whether the object was already destroyed
[const]	bool	_is_const_object?		Returns a value indicating whether the reference is a const reference
	void	_manage		Marks the object as managed by the script side.
	void	_unmanage		Marks the object as no longer owned by the script side.
[const]	double	abs		Returns the length of the vector
	void	assign	(const DVector other)	Assigns another object to self
[const]	new DVector ptr	dup		Creates a copy of self
[const]	unsigned long	hash		Computes a hash value
[const]	double	length		Returns the length of the vector
[const]	double	sprod	(const DVector v)	Computes the scalar product between self and the given vector
[const]	int	sprod_sign	(const DVector v)	Computes the scalar product between self and the given vector and returns a value indicating the sign of the product
[const]	double	sq_abs		The square length of the vector
[const]	double	sq_length		The square length of the vector
[const]	Vector	to_itype	(double dbu = 1)	Converts the point to an integer coordinate point
[const]	DPoint	to_p		Turns the vector into a point
[const]	string	to_s	(double dbu = 0)	String conversion
[const]	double	vprod	(const DVector v)	Computes the vector product between self and the given vector
[const]	int	vprod_sign	(const DVector v)	Computes the vector product between self and the given vector and returns a value indicating the sign of the product
[const]	double	x		Accessor to the x coordinate
	void	x=	(double coord)	Write accessor to the x coordinate
[const]	double	y		Accessor to the y coordinate
	void	y=	(double coord)	Write accessor to the y coordinate

Public static methods and constants

new DVector ptr	**from_s**	(string s)	Creates an object from a string

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

!=

Signature: *[const]* bool **!=** (const DVector v)

Description: Inequality test operator

*****

(1) Signature: *[const]* DVector ***** (double f)

Description: Scaling by some factor

Returns the scaled object. All coordinates are multiplied with the given factor and if necessary rounded.

Python specific notes:
This method also implements '__rmul__'.

(2) Signature: *[const]* double ***** (const DVector v)

Description: Computes the scalar product between self and the given vector

The scalar product of a and b is defined as: vp = ax*bx+ay*by.

Python specific notes:
This method also implements '__rmul__'.

***=**

Signature: DVector ***=** (double f)

Description: Scaling by some factor

Scales object in place. All coordinates are multiplied with the given factor and if necessary rounded.

+

(1) Signature: *[const]* DVector **+** (const DVector v)

Description: Adds two vectors

Adds vector v to self by adding the coordinates.

(2) Signature: *[const]* DPoint **+** (const DPoint p)

Description: Adds a vector and a point

Returns the point p shifted by the vector.

-	**Signature**: *[const]* DVector **-** (const DVector v) **Description**: Subtract two vectors Subtract vector v from self by subtracting the coordinates.
-@	**Signature**: *[const]* DVector **-@** **Description**: Compute the negative of a vector Returns a new vector with -x,-y.
/	**Signature**: *[const]* DVector **/** (double d) **Description**: Division by some divisor Returns the scaled object. All coordinates are divided with the given divisor and if necessary rounded.
/=	**Signature**: DVector **/=** (double d) **Description**: Division by some divisor Divides the object in place. All coordinates are divided with the given divisor and if necessary rounded.
<	**Signature**: *[const]* bool **<** (const DVector v) **Description**: "less" comparison operator This operator is provided to establish a sorting order
==	**Signature**: *[const]* bool **==** (const DVector v) **Description**: Equality test operator
_create	**Signature**: void **_create** **Description**: Ensures the C++ object is created Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
_destroy	**Signature**: void **_destroy** **Description**: Explicitly destroys the object Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
_destroyed?	**Signature**: *[const]* bool **_destroyed?** **Description**: Returns a value indicating whether the object was already destroyed This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
_is_const_object?	**Signature**: *[const]* bool **_is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

abs

Signature: *[const]* double **abs**

Description: Returns the length of the vector

'abs' is an alias provided for compatibility with the former point type.

assign

Signature: void **assign** (const DVector other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new DVector ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

from_s

Signature: *[static]* new DVector ptr **from_s** (string s)

Description: Creates an object from a string

Creates the object from a string representation (as returned by to_s)

hash

Signature: *[const]* unsigned long **hash**

Description: Computes a hash value

Returns a hash value for the given vector. This method enables vectors as hash keys.

This method has been introduced in version 0.25.

Python specific notes:
This method is also available as 'hash(object)'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

length

Signature: *[const]* double **length**

Description: Returns the length of the vector

'abs' is an alias provided for compatibility with the former point type.

new

(1) Signature: *[static]* new DVector ptr **new** (const Vector vector)

Description: Creates a floating-point coordinate vector from an integer coordinate vector

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new DVector ptr **new**

Description: Default constructor: creates a null vector with coordinates (0,0)

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new DVector ptr **new** (const DPoint p)

Description: Default constructor: creates a vector from a point

This constructor is equivalent to computing p-point(0,0). This method has been introduced in version 0.25.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new DVector ptr **new** (double x, double y)

Description: Constructor for a vector from two coordinate values

Python specific notes:
This method is the default initializer of the object.

sprod

Signature: *[const]* double **sprod** (const DVector v)

Description: Computes the scalar product between self and the given vector

The scalar product of a and b is defined as: vp = ax*bx+ay*by.

sprod_sign

Signature: *[const]* int **sprod_sign** (const DVector v)

Description: Computes the scalar product between self and the given vector and returns a value indicating the sign of the product

Returns: 1 if the scalar product is positive, 0 if it is zero and -1 if it is negative.

sq_abs

Signature: *[const]* double **sq_abs**

Description: The square length of the vector

'sq_abs' is an alias provided for compatibility with the former point type.

sq_length

Signature: *[const]* double **sq_length**

Description: The square length of the vector

'sq_abs' is an alias provided for compatibility with the former point type.

to_itype

Signature: *[const]* Vector **to_itype** (double dbu = 1)

Description: Converts the point to an integer coordinate point

The database unit can be specified to translate the floating-point coordinate vector in micron units to an integer-coordinate vector in database units. The vector's' coordinates will be divided by the database unit.

to_p

Signature: *[const]* DPoint **to_p**

Description: Turns the vector into a point

This method returns the point resulting from adding the vector to (0,0). This method has been introduced in version 0.25.

to_s

Signature: *[const]* string **to_s** (double dbu = 0)

Description: String conversion

If a DBU is given, the output units will be micrometers.

The DBU argument has been added in version 0.27.6.

Python specific notes:
This method is also available as 'str(object)'.

vprod

Signature: *[const]* double **vprod** (const DVector v)

Description: Computes the vector product between self and the given vector

The vector product of a and b is defined as: vp = ax*by-ay*bx.

vprod_sign

Signature: *[const]* int **vprod_sign** (const DVector v)

Description: Computes the vector product between self and the given vector and returns a value indicating the sign of the product

Returns: 1 if the vector product is positive, 0 if it is zero and -1 if it is negative.

x

Signature: *[const]* double **x**

Description: Accessor to the x coordinate

Python specific notes:
The object exposes a readable attribute 'x'. This is the getter.

x=

Signature: void **x=** (double coord)

Description: Write accessor to the x coordinate

Python specific notes:
The object exposes a writable attribute 'x'. This is the setter.

y

Signature: *[const]* double **y**

Description: Accessor to the y coordinate

Python specific notes:
The object exposes a readable attribute 'y'. This is the getter.

y=

Signature: void **y=** (double coord)

Description: Write accessor to the y coordinate

Python specific notes:
The object exposes a writable attribute 'y'. This is the setter.

4.113. API reference - Class Vector

Notation used in Ruby API documentation

Module: db

Description: A integer vector class

A vector is a distance in cartesian, 2 dimensional space. A vector is given by two coordinates (x and y) and represents the distance between two points. Being the distance, transformations act differently on vectors: the displacement is not applied. Vectors are not geometrical objects by itself. But they are frequently used in the database API for various purposes.

This class has been introduced in version 0.25.

See The Database API for more details about the database objects.

Public constructors

new Vector ptr	**new**	(const DVector dvector)	Creates an integer coordinate vector from a floating-point coordinate vector
new Vector ptr	**new**		Default constructor: creates a null vector with coordinates (0,0)
new Vector ptr	**new**	(const Point p)	Default constructor: creates a vector from a point
new Vector ptr	**new**	(int x, int y)	Constructor for a vector from two coordinate values

Public methods

[const]	bool	**!=**	(const Vector v)	Inequality test operator
[const]	Vector	*****	(double f)	Scaling by some factor
[const]	long	*****	(const Vector v)	Computes the scalar product between self and the given vector
	Vector	***=**	(double f)	Scaling by some factor
[const]	Vector	**+**	(const Vector v)	Adds two vectors
[const]	Point	**+**	(const Point p)	Adds a vector and a point
[const]	Vector	**-**	(const Vector v)	Subtract two vectors
[const]	Vector	**-@**		Compute the negative of a vector
[const]	Vector	***/***	(double d)	Division by some divisor
	Vector	***/=***	(double d)	Division by some divisor
[const]	bool	**<**	(const Vector v)	"less" comparison operator
[const]	bool	**==**	(const Vector v)	Equality test operator
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object

[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	double	**abs**		Returns the length of the vector
	void	**assign**	(const Vector other)	Assigns another object to self
[const]	new Vector ptr	**dup**		Creates a copy of self
[const]	unsigned long	**hash**		Computes a hash value
[const]	double	**length**		Returns the length of the vector
[const]	long	**sprod**	(const Vector v)	Computes the scalar product between self and the given vector
[const]	int	**sprod_sign**	(const Vector v)	Computes the scalar product between self and the given vector and returns a value indicating the sign of the product
[const]	double	**sq_abs**		The square length of the vector
[const]	double	**sq_length**		The square length of the vector
[const]	DVector	**to_dtype**	(double dbu = 1)	Converts the vector to a floating-point coordinate vector
[const]	Point	**to_p**		Turns the vector into a point
[const]	string	**to_s**	(double dbu = 0)	String conversion
[const]	long	**vprod**	(const Vector v)	Computes the vector product between self and the given vector
[const]	int	**vprod_sign**	(const Vector v)	Computes the vector product between self and the given vector and returns a value indicating the sign of the product
[const]	int	**x**		Accessor to the x coordinate
	void	**x=**	(int coord)	Write accessor to the x coordinate
[const]	int	**y**		Accessor to the y coordinate
	void	**y=**	(int coord)	Write accessor to the y coordinate

Public static methods and constants

new Vector ptr	**from_s**	(string s)	Creates an object from a string

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

!=

Signature: *[const]* bool **!=** (const Vector v)

Description: Inequality test operator

*****

(1) Signature: *[const]* Vector ***** (double f)

Description: Scaling by some factor

Returns the scaled object. All coordinates are multiplied with the given factor and if necessary rounded.

Python specific notes:
This method also implements '__rmul__'.

(2) Signature: *[const]* long ***** (const Vector v)

Description: Computes the scalar product between self and the given vector

The scalar product of a and b is defined as: vp = ax*bx+ay*by.

Python specific notes:
This method also implements '__rmul__'.

***=**

Signature: Vector ***=** (double f)

Description: Scaling by some factor

Scales object in place. All coordinates are multiplied with the given factor and if necessary rounded.

+

(1) Signature: *[const]* Vector **+** (const Vector v)

Description: Adds two vectors

Adds vector v to self by adding the coordinates.

(2) Signature: *[const]* Point **+** (const Point p)

Description: Adds a vector and a point

Returns the point p shifted by the vector.

-	**Signature**: *[const]* Vector **-** (const Vector v) **Description**: Subtract two vectors Subtract vector v from self by subtracting the coordinates.
-@	**Signature**: *[const]* Vector **-@** **Description**: Compute the negative of a vector Returns a new vector with -x,-y.
/	**Signature**: *[const]* Vector **/** (double d) **Description**: Division by some divisor Returns the scaled object. All coordinates are divided with the given divisor and if necessary rounded.
/=	**Signature**: Vector **/=** (double d) **Description**: Division by some divisor Divides the object in place. All coordinates are divided with the given divisor and if necessary rounded.
<	**Signature**: *[const]* bool **<** (const Vector v) **Description**: "less" comparison operator This operator is provided to establish a sorting order
==	**Signature**: *[const]* bool **==** (const Vector v) **Description**: Equality test operator
_create	**Signature**: void **_create** **Description**: Ensures the C++ object is created Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
_destroy	**Signature**: void **_destroy** **Description**: Explicitly destroys the object Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
_destroyed?	**Signature**: *[const]* bool **_destroyed?** **Description**: Returns a value indicating whether the object was already destroyed This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
_is_const_object?	**Signature**: *[const]* bool **_is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

abs

Signature: *[const]* double **abs**

Description: Returns the length of the vector

'abs' is an alias provided for compatibility with the former point type.

assign

Signature: void **assign** (const Vector other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new Vector ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

from_s

Signature: *[static]* new Vector ptr **from_s** (string s)

Description: Creates an object from a string

Creates the object from a string representation (as returned by to_s)

hash

Signature: *[const]* unsigned long **hash**

Description: Computes a hash value

Returns a hash value for the given vector. This method enables vectors as hash keys.

This method has been introduced in version 0.25.

Python specific notes:
This method is also available as 'hash(object)'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

length

Signature: *[const]* double **length**

Description: Returns the length of the vector

'abs' is an alias provided for compatibility with the former point type.

new

(1) Signature: *[static]* new Vector ptr **new** (const DVector dvector)

Description: Creates an integer coordinate vector from a floating-point coordinate vector

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new Vector ptr **new**

Description: Default constructor: creates a null vector with coordinates (0,0)

Python specific notes:
This method is the default initializer of the object.

(3) Signature: *[static]* new Vector ptr **new** (const Point p)

Description: Default constructor: creates a vector from a point

This constructor is equivalent to computing p-point(0,0). This method has been introduced in version 0.25.

Python specific notes:
This method is the default initializer of the object.

(4) Signature: *[static]* new Vector ptr **new** (int x, int y)

Description: Constructor for a vector from two coordinate values

Python specific notes:
This method is the default initializer of the object.

sprod

Signature: *[const]* long **sprod** (const Vector v)

Description: Computes the scalar product between self and the given vector

The scalar product of a and b is defined as: vp = ax*bx+ay*by.

sprod_sign

Signature: *[const]* int **sprod_sign** (const Vector v)

Description: Computes the scalar product between self and the given vector and returns a value indicating the sign of the product

Returns: 1 if the scalar product is positive, 0 if it is zero and -1 if it is negative.

sq_abs

Signature: *[const]* double **sq_abs**

Description: The square length of the vector

'sq_abs' is an alias provided for compatibility with the former point type.

sq_length

Signature: *[const]* double **sq_length**

Description: The square length of the vector

'sq_abs' is an alias provided for compatibility with the former point type.

to_dtype

Signature: *[const]* DVector **to_dtype** (double dbu = 1)

Description: Converts the vector to a floating-point coordinate vector

The database unit can be specified to translate the integer-coordinate vector into a floating-point coordinate vector in micron units. The database unit is basically a scaling factor.

to_p

Signature: *[const]* Point **to_p**

Description: Turns the vector into a point

This method returns the point resulting from adding the vector to (0,0). This method has been introduced in version 0.25.

to_s

Signature: *[const]* string **to_s** (double dbu = 0)

Description: String conversion

If a DBU is given, the output units will be micrometers.

The DBU argument has been added in version 0.27.6.

Python specific notes:
This method is also available as 'str(object)'.

vprod

Signature: *[const]* long **vprod** (const Vector v)

Description: Computes the vector product between self and the given vector

The vector product of a and b is defined as: vp = ax*by-ay*bx.

vprod_sign

Signature: *[const]* int **vprod_sign** (const Vector v)

Description: Computes the vector product between self and the given vector and returns a value indicating the sign of the product

Returns: 1 if the vector product is positive, 0 if it is zero and -1 if it is negative.

x

Signature: *[const]* int **x**

Description: Accessor to the x coordinate

Python specific notes:
The object exposes a readable attribute 'x'. This is the getter.

x=

Signature: void **x=** (int coord)

Description: Write accessor to the x coordinate

Python specific notes:
The object exposes a writable attribute 'x'. This is the setter.

y

Signature: *[const]* int **y**

Description: Accessor to the y coordinate

Python specific notes:
The object exposes a readable attribute 'y'. This is the getter.

y=

Signature: void **y=** (int coord)

Description: Write accessor to the y coordinate

Python specific notes:
The object exposes a writable attribute 'y'. This is the setter.

4.114. API reference - Class LayoutDiff

Notation used in Ruby API documentation

Module: db

Description: The layout compare tool

The layout compare tool is a facility to quickly compare layouts and derive events that give details about the differences. The events are basically emitted following a certain order:

- General configuration events (database units, layers ...)
- on_begin_cell
- on_begin_inst_differences (if the instances differ)
- details about instance differences (if Verbose flag is given)
- on_end_inst_differences (if the instances differ)
- on_begin_layer
- on_begin_polygon_differences (if the polygons differ)
- details about polygon differences (if Verbose flag is given)
- on_end_polygon_differences (if the polygons differ)
- other shape difference events (paths, boxes, ...)
- on_end_layer
- repeated layer event groups
- on_end_cell
- repeated cell event groups

To use the diff facility, create a LayoutDiff object and call the compare_layout or compare_cell method:

```
lya = ... # layout A
lyb = ... # layout B

diff = RBA::LayoutDiff::new
diff.on_polygon_in_a_only do |poly|
  puts "Polygon in A: #{diff.cell_a.name}@#{diff.layer_info_a.to_s}: #{poly.to_s}"
end
diff.on_polygon_in_b_only do |poly|
  puts "Polygon in A: #{diff.cell_b.name}@#{diff.layer_info_b.to_s}: #{poly.to_s}"
end
diff.compare(lya, lyb, RBA::LayoutDiff::Verbose + RBA::LayoutDiff::NoLayerNames)
```

Public constructors

new LayoutDiff ptr	**new**	Creates a new object of this class

Public methods

	void	_create		Ensures the C++ object is created
	void	_destroy		Explicitly destroys the object
[const]	bool	_destroyed?		Returns a value indicating whether the object was already destroyed
[const]	bool	_is_const_object?		Returns a value indicating whether the reference is a const reference
	void	_manage		Marks the object as managed by the script side.
	void	_unmanage		Marks the object as no longer owned by the script side.
	void	assign	(const LayoutDiff other)	Assigns another object to self
[const]	const Cell ptr	cell_a		Gets the current cell for the first layout
[const]	const Cell ptr	cell_b		Gets the current cell for the second layout
	bool	compare	(const Layout ptr a, const Layout ptr b, unsigned int flags = 0, int tolerance = 0)	Compares two layouts
	bool	compare	(const Cell ptr a, const Cell ptr b, unsigned int flags = 0, int tolerance = 0)	Compares two cells
[const]	new LayoutDiff ptr	dup		Creates a copy of self
[const]	int	layer_index_a		Gets the current layer for the first layout
[const]	int	layer_index_b		Gets the current layer for the second layout
[const]	LayerInfo	layer_info_a		Gets the current layer properties for the first layout
[const]	LayerInfo	layer_info_b		Gets the current layer properties for the second layout
[const]	const Layout ptr	layout_a		Gets the first layout the difference detector runs on
[const]	const Layout ptr	layout_b		Gets the second layout the difference detector runs on
[signal]	void	on_bbox_differs	(const Box ba, const Box bb)	This signal indicates a difference in the bounding boxes of two cells

[signal]	void	**on_begin_box_differences**		This signal indicates differences in the boxes on the current layer
[signal]	void	**on_begin_cell**	(const Cell ptr ca, const Cell ptr cb)	This signal indicates the sequence of events for a cell pair
[signal]	void	**on_begin_edge_differences**		This signal indicates differences in the edges on the current layer
[signal]	void	**on_begin_edge_pair_dif**		This signal indicates differences in the edge pairs on the current layer
[signal]	void	**on_begin_inst_differences**		This signal indicates differences in the cell instances
[signal]	void	**on_begin_layer**	(const LayerInfo layer, int layer_index_a, int layer_index_b)	This signal indicates differences on the given layer
[signal]	void	**on_begin_path_differences**		This signal indicates differences in the paths on the current layer
[signal]	void	**on_begin_polygon_diffe**		This signal indicates differences in the polygons on the current layer
[signal]	void	**on_begin_text_differences**		This signal indicates differences in the texts on the current layer
[signal]	void	**on_box_in_a_only**	(const Box anotb, unsigned long prop_id)	This signal indicates a box that is present in the first layout only
[signal]	void	**on_box_in_b_only**	(const Box bnota, unsigned long prop_id)	This signal indicates a box that is present in the second layout only
[signal]	void	**on_cell_in_a_only**	(const Cell ptr c)	This signal indicates that the given cell is only present in the first layout
[signal]	void	**on_cell_in_b_only**	(const Cell ptr c)	This signal indicates that the given cell is only present in the second layout
[signal]	void	**on_cell_meta_info_differ**	(string name, variant a, variant b)	This signal indicates that meta info between the current cells differs
[signal]	void	**on_cell_name_differs**	(const Cell ptr ca, const Cell ptr cb)	This signal indicates a difference in the cell names
[signal]	void	**on_dbu_differs**	(double dbu_a, double dbu_b)	This signal indicates a difference in the database units of the layouts
[signal]	void	**on_edge_in_a_only**	(const Edge anotb, unsigned long prop_id)	This signal indicates an edge that is present in the first layout only
[signal]	void	**on_edge_in_b_only**	(const Edge bnota,	This signal indicates an edge that is present in the second layout only

			unsigned long prop_id)	
[signal]	void	**on_edge_pair_in_a_only**	(const EdgePair anotb, unsigned long prop_id)	This signal indicates an edge pair that is present in the first layout only
[signal]	void	**on_edge_pair_in_b_only**	(const EdgePair bnota, unsigned long prop_id)	This signal indicates an edge pair that is present in the second layout only
[signal]	void	**on_end_box_differences**		This signal indicates the end of sequence of box differences
[signal]	void	**on_end_cell**		This signal indicates the end of a sequence of signals for a specific cell
[signal]	void	**on_end_edge_differences**		This signal indicates the end of sequence of edge differences
[signal]	void	**on_end_edge_pair_diffe**		This signal indicates the end of sequence of edge pair differences
[signal]	void	**on_end_inst_differences**		This signal finishes a sequence of detailed instance difference events
[signal]	void	**on_end_layer**		This signal indicates the end of a sequence of signals for a specific layer
[signal]	void	**on_end_path_differences**		This signal indicates the end of sequence of path differences
[signal]	void	**on_end_polygon_differe**		This signal indicates the end of sequence of polygon differences
[signal]	void	**on_end_text_differences**		This signal indicates the end of sequence of text differences
[signal]	void	**on_instance_in_a_only**	(const CellInstArray anotb, unsigned long prop_id)	This signal indicates an instance that is present only in the first layout
[signal]	void	**on_instance_in_b_only**	(const CellInstArray bnota, unsigned long prop_id)	This signal indicates an instance that is present only in the second layout
[signal]	void	**on_layer_in_a_only**	(const LayerInfo a)	This signal indicates a layer that is present only in the first layout
[signal]	void	**on_layer_in_b_only**	(const LayerInfo b)	This signal indicates a layer that is present only in the second layout

[signal]	void	**on_layer_name_differs**	(const LayerInfo a, const LayerInfo b)	This signal indicates a difference in the layer names
[signal]	void	**on_layout_meta_info_differs**	(string name, variant a, variant b)	This signal indicates that global meta info differs
[signal]	void	**on_path_in_a_only**	(const Path anotb, unsigned long prop_id)	This signal indicates a path that is present in the first layout only
[signal]	void	**on_path_in_b_only**	(const Path bnota, unsigned long prop_id)	This signal indicates a path that is present in the second layout only
[signal]	void	**on_per_layer_bbox_diffe**	(const Box ba, const Box bb)	This signal indicates differences in the per-layer bounding boxes of the current cell
[signal]	void	**on_polygon_in_a_only**	(const Polygon anotb, unsigned long prop_id)	This signal indicates a polygon that is present in the first layout only
[signal]	void	**on_polygon_in_b_only**	(const Polygon bnota, unsigned long prop_id)	This signal indicates a polygon that is present in the second layout only
[signal]	void	**on_text_in_a_only**	(const Text anotb, unsigned long prop_id)	This signal indicates a text that is present in the first layout only
[signal]	void	**on_text_in_b_only**	(const Text bnota, unsigned long prop_id)	This signal indicates a text that is present in the second layout only

Public static methods and constants

[static,const]	unsigned int	**BoxesAsPolygons**	Compare boxes to polygons
[static,const]	unsigned int	**DontSummarizeMissingLayers**	Don't summarize missing layers
[static,const]	unsigned int	**FlattenArrayInsts**	Compare array instances instance by instance
[static,const]	unsigned int	**IgnoreDuplicates**	Ignore duplicate instances or shapes
[static,const]	unsigned int	**NoLayerNames**	Do not compare layer names
[static,const]	unsigned int	**NoProperties**	Ignore properties
[static,const]	unsigned int	**NoTextDetails**	Ignore text details (font, size, presentation)
[static,const]	unsigned int	**NoTextOrientation**	Ignore text orientation
[static,const]	unsigned int	**PathsAsPolygons**	Compare paths to polygons

[static,const]	unsigned int	**Silent**	Silent compare - just report whether the layouts are identical
[static,const]	unsigned int	**SmartCellMapping**	Derive smart cell mapping instead of name mapping (available only if top cells are specified)
[static,const]	unsigned int	**Verbose**	Enables verbose mode (gives details about the differences)
[static,const]	unsigned int	**WithMetaInfo**	Ignore meta info

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

BoxesAsPolygons

Signature: *[static,const]* unsigned int **BoxesAsPolygons**

Description: Compare boxes to polygons

This constant can be used for the flags parameter of compare_layouts and compare_cells. It can be combined with other constants to form a flag set.

Python specific notes:
The object exposes a readable attribute 'BoxesAsPolygons'. This is the getter.

DontSummarizeMissingLayers

Signature: *[static,const]* unsigned int **DontSummarizeMissingLayers**

Description: Don't summarize missing layers

If this mode is present, missing layers are treated as empty ones and every shape on the other layer will be reported as difference.

This constant can be used for the flags parameter of compare_layouts and compare_cells. It can be combined with other constants to form a flag set.

Python specific notes:
The object exposes a readable attribute 'DontSummarizeMissingLayers'. This is the getter.

FlattenArrayInsts

Signature: *[static,const]* unsigned int **FlattenArrayInsts**

Description: Compare array instances instance by instance

This constant can be used for the flags parameter of compare_layouts and compare_cells. It can be combined with other constants to form a flag set.

Python specific notes:
The object exposes a readable attribute 'FlattenArrayInsts'. This is the getter.

IgnoreDuplicates

Signature: *[static,const]* unsigned int **IgnoreDuplicates**

Description: Ignore duplicate instances or shapes

With this option present, duplicate instances or shapes are ignored and duplication does not count as a difference.

This option has been introduced in version 0.28.9.

Python specific notes:
The object exposes a readable attribute 'IgnoreDuplicates'. This is the getter.

NoLayerNames

Signature: *[static,const]* unsigned int **NoLayerNames**

Description: Do not compare layer names

This constant can be used for the flags parameter of compare_layouts and compare_cells. It can be combined with other constants to form a flag set.

Python specific notes:
The object exposes a readable attribute 'NoLayerNames'. This is the getter.

NoProperties

Signature: *[static,const]* unsigned int **NoProperties**

Description: Ignore properties

This constant can be used for the flags parameter of compare_layouts and compare_cells. It can be combined with other constants to form a flag set.

Python specific notes:
The object exposes a readable attribute 'NoProperties'. This is the getter.

NoTextDetails

Signature: *[static,const]* unsigned int **NoTextDetails**

Description: Ignore text details (font, size, presentation)

This constant can be used for the flags parameter of compare_layouts and compare_cells. It can be combined with other constants to form a flag set.

Python specific notes:
The object exposes a readable attribute 'NoTextDetails'. This is the getter.

NoTextOrientation

Signature: *[static,const]* unsigned int **NoTextOrientation**

Description: Ignore text orientation

This constant can be used for the flags parameter of compare_layouts and compare_cells. It can be combined with other constants to form a flag set.

Python specific notes:
The object exposes a readable attribute 'NoTextOrientation'. This is the getter.

PathsAsPolygons

Signature: *[static,const]* unsigned int **PathsAsPolygons**

Description: Compare paths to polygons

This constant can be used for the flags parameter of compare_layouts and compare_cells. It can be combined with other constants to form a flag set.

Python specific notes:
The object exposes a readable attribute 'PathsAsPolygons'. This is the getter.

Silent

Signature: *[static,const]* unsigned int **Silent**

Description: Silent compare - just report whether the layouts are identical

Silent mode will not issue any signals, but instead the return value of the LayoutDiff#compare method will indicate whether the layouts are identical. In silent mode, the compare method will return immediately once a difference has been encountered so that mode may be much faster than the full compare.

This constant can be used for the flags parameter of compare_layouts and compare_cells. It can be combined with other constants to form a flag set.

Python specific notes:
The object exposes a readable attribute 'Silent'. This is the getter.

SmartCellMapping

Signature: *[static,const]* unsigned int **SmartCellMapping**

Description: Derive smart cell mapping instead of name mapping (available only if top cells are specified)

Smart cell mapping is only effective currently when cells are compared (with LayoutDiff#compare with cells instead of layout objects).

This constant can be used for the flags parameter of compare_layouts and compare_cells. It can be combined with other constants to form a flag set.

Python specific notes:
The object exposes a readable attribute 'SmartCellMapping'. This is the getter.

Verbose

Signature: *[static,const]* unsigned int **Verbose**

Description: Enables verbose mode (gives details about the differences)

See the event descriptions for details about the differences in verbose and non-verbose mode.

This constant can be used for the flags parameter of compare_layouts and compare_cells. It can be combined with other constants to form a flag set.

Python specific notes:
The object exposes a readable attribute 'Verbose'. This is the getter.

WithMetaInfo

Signature: *[static,const]* unsigned int **WithMetaInfo**

Description: Ignore meta info

This constant can be used for the flags parameter of compare_layouts and compare_cells. It can be combined with other constants to form a flag set. If present, this option tells the compare algorithm to include persisted meta info in the compare.

This flag has been introduced in version 0.28.16.

Python specific notes:
The object exposes a readable attribute 'WithMetaInfo'. This is the getter.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const LayoutDiff other)

Description: Assigns another object to self

cell_a

Signature: *[const]* const Cell ptr **cell_a**

Description: Gets the current cell for the first layout

This attribute is the current cell and is set after on_begin_cell and reset after on_end_cell.

cell_b

Signature: *[const]* const Cell ptr **cell_b**

Description: Gets the current cell for the second layout

This attribute is the current cell and is set after on_begin_cell and reset after on_end_cell.

compare

(1) Signature: bool **compare** (const Layout ptr a, const Layout ptr b, unsigned int flags = 0, int tolerance = 0)

Description: Compares two layouts

a:	The first input layout
b:	The second input layout
flags:	Flags to use for the comparison
tolerance:	A coordinate tolerance to apply (0: exact match, 1: one DBU tolerance is allowed ...)
Returns:	True, if the layouts are identical

Compares layer definitions, cells, instances and shapes and properties. Cells are identified by name. Only layers with valid layer and datatype are compared. Several flags can be specified as a bitwise or combination of the constants.

(2) Signature: bool **compare** (const Cell ptr a, const Cell ptr b, unsigned int flags = 0, int tolerance = 0)

Description: Compares two cells

a:	The first top cell
b:	The second top cell
flags:	Flags to use for the comparison
tolerance:	A coordinate tolerance to apply (0: exact match, 1: one DBU tolerance is allowed ...)
Returns:	True, if the cells are identical

Compares layer definitions, cells, instances and shapes and properties of two layout hierarchies starting from the given cells. Cells are identified by name. Only layers with valid layer and datatype are compared. Several flags can be specified as a bitwise or combination of the constants.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new LayoutDiff ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

layer_index_a	**Signature**: *[const]* int **layer_index_a** **Description**: Gets the current layer for the first layout This attribute is the current cell and is set after on_begin_layer and reset after on_end_layer.
layer_index_b	**Signature**: *[const]* int **layer_index_b** **Description**: Gets the current layer for the second layout This attribute is the current cell and is set after on_begin_layer and reset after on_end_layer.
layer_info_a	**Signature**: *[const]* LayerInfo **layer_info_a** **Description**: Gets the current layer properties for the first layout This attribute is the current cell and is set after on_begin_layer and reset after on_end_layer.
layer_info_b	**Signature**: *[const]* LayerInfo **layer_info_b** **Description**: Gets the current layer properties for the second layout This attribute is the current cell and is set after on_begin_layer and reset after on_end_layer.
layout_a	**Signature**: *[const]* const Layout ptr **layout_a** **Description**: Gets the first layout the difference detector runs on
layout_b	**Signature**: *[const]* const Layout ptr **layout_b** **Description**: Gets the second layout the difference detector runs on
new	**Signature**: *[static]* new LayoutDiff ptr **new** **Description**: Creates a new object of this class **Python specific notes:** This method is the default initializer of the object.
on_bbox_differs	**Signature**: *[signal]* void **on_bbox_differs** (const Box ba, const Box bb) **Description**: This signal indicates a difference in the bounding boxes of two cells This signal is only emitted in non-verbose mode (without Verbose flag) as a summarizing cell property. In verbose mode detailed events will be issued indicating the differences. **Python specific notes:** The object exposes a readable attribute 'on_bbox_differs'. This is the getter. The object exposes a writable attribute 'on_bbox_differs'. This is the setter.
on_begin_box_differences	**Signature**: *[signal]* void **on_begin_box_differences** **Description**: This signal indicates differences in the boxes on the current layer The current layer is indicated by the begin_layer_event signal or can be obtained from the diff object through LayoutDiff#layer_info_a, LayoutDiff#layer_index_a, LayoutDiff#layer_info_b and LayoutDiff#layer_index_b. In verbose mode (see Verbose flag) more signals will be emitted for boxes that are different between the two layouts. **Python specific notes:** The object exposes a readable attribute 'on_begin_box_differences'. This is the getter. The object exposes a writable attribute 'on_begin_box_differences'. This is the setter.

on_begin_cell

Signature: *[signal]* void **on_begin_cell** (const Cell ptr ca, const Cell ptr cb)

Description: This signal indicates the sequence of events for a cell pair

All cell specific events happen between begin_cell_event and end_cell_event signals.

Python specific notes:
The object exposes a readable attribute 'on_begin_cell'. This is the getter.
The object exposes a writable attribute 'on_begin_cell'. This is the setter.

on_begin_edge_differences

Signature: *[signal]* void **on_begin_edge_differences**

Description: This signal indicates differences in the edges on the current layer

The current layer is indicated by the begin_layer_event signal or can be obtained from the diff object through LayoutDiff#layer_info_a, LayoutDiff#layer_index_a, LayoutDiff#layer_info_b and LayoutDiff#layer_index_b. In verbose mode (see Verbose flag) more signals will be emitted for edges that are different between the two layouts.

Python specific notes:
The object exposes a readable attribute 'on_begin_edge_differences'. This is the getter.
The object exposes a writable attribute 'on_begin_edge_differences'. This is the setter.

on_begin_edge_pair_differences

Signature: *[signal]* void **on_begin_edge_pair_differences**

Description: This signal indicates differences in the edge pairs on the current layer

The current layer is indicated by the begin_layer_event signal or can be obtained from the diff object through LayoutDiff#layer_info_a, LayoutDiff#layer_index_a, LayoutDiff#layer_info_b and LayoutDiff#layer_index_b. In verbose mode (see Verbose flag) more signals will be emitted for edge pairs that are different between the two layouts. This event has been introduced in version 0.28.

Python specific notes:
The object exposes a readable attribute 'on_begin_edge_pair_differences'. This is the getter.
The object exposes a writable attribute 'on_begin_edge_pair_differences'. This is the setter.

on_begin_inst_differences

Signature: *[signal]* void **on_begin_inst_differences**

Description: This signal indicates differences in the cell instances

In verbose mode (see Verbose) more events will follow that indicate the instances that are present only in the first and second layout (instance_in_a_only_event and instance_in_b_only_event).

Python specific notes:
The object exposes a readable attribute 'on_begin_inst_differences'. This is the getter.
The object exposes a writable attribute 'on_begin_inst_differences'. This is the setter.

on_begin_layer

Signature: *[signal]* void **on_begin_layer** (const LayerInfo layer, int layer_index_a, int layer_index_b)

Description: This signal indicates differences on the given layer

In verbose mode (see Verbose) more events will follow that indicate the instances that are present only in the first and second layout (polygon_in_a_only_event, polygon_in_b_only_event and similar).

Python specific notes:
The object exposes a readable attribute 'on_begin_layer'. This is the getter.
The object exposes a writable attribute 'on_begin_layer'. This is the setter.

on_begin_path_differences

Signature: *[signal]* void **on_begin_path_differences**

Description: This signal indicates differences in the paths on the current layer

The current layer is indicated by the begin_layer_event signal or can be obtained from the diff object through LayoutDiff#layer_info_a, LayoutDiff#layer_index_a, LayoutDiff#layer_info_b and

	LayoutDiff#layer_index_b. In verbose mode (see Verbose flag) more signals will be emitted for paths that are different between the two layouts. **Python specific notes:** The object exposes a readable attribute 'on_begin_path_differences'. This is the getter. The object exposes a writable attribute 'on_begin_path_differences'. This is the setter.
on_begin_polygon_differences	**Signature**: *[signal]* void **on_begin_polygon_differences** **Description**: This signal indicates differences in the polygons on the current layer The current layer is indicated by the begin_layer_event signal or can be obtained from the diff object through LayoutDiff#layer_info_a, LayoutDiff#layer_index_a, LayoutDiff#layer_info_b and LayoutDiff#layer_index_b. In verbose mode (see Verbose flag) more signals will be emitted for polygons that are different between the two layouts. **Python specific notes:** The object exposes a readable attribute 'on_begin_polygon_differences'. This is the getter. The object exposes a writable attribute 'on_begin_polygon_differences'. This is the setter.
on_begin_text_differences	**Signature**: *[signal]* void **on_begin_text_differences** **Description**: This signal indicates differences in the texts on the current layer The current layer is indicated by the begin_layer_event signal or can be obtained from the diff object through LayoutDiff#layer_info_a, LayoutDiff#layer_index_a, LayoutDiff#layer_info_b and LayoutDiff#layer_index_b. In verbose mode (see Verbose flag) more signals will be emitted for texts that are different between the two layouts. **Python specific notes:** The object exposes a readable attribute 'on_begin_text_differences'. This is the getter. The object exposes a writable attribute 'on_begin_text_differences'. This is the setter.
on_box_in_a_only	**Signature**: *[signal]* void **on_box_in_a_only** (const Box anotb, unsigned long prop_id) **Description**: This signal indicates a box that is present in the first layout only **Python specific notes:** The object exposes a readable attribute 'on_box_in_a_only'. This is the getter. The object exposes a writable attribute 'on_box_in_a_only'. This is the setter.
on_box_in_b_only	**Signature**: *[signal]* void **on_box_in_b_only** (const Box bnota, unsigned long prop_id) **Description**: This signal indicates a box that is present in the second layout only **Python specific notes:** The object exposes a readable attribute 'on_box_in_b_only'. This is the getter. The object exposes a writable attribute 'on_box_in_b_only'. This is the setter.
on_cell_in_a_only	**Signature**: *[signal]* void **on_cell_in_a_only** (const Cell ptr c) **Description**: This signal indicates that the given cell is only present in the first layout **Python specific notes:** The object exposes a readable attribute 'on_cell_in_a_only'. This is the getter. The object exposes a writable attribute 'on_cell_in_a_only'. This is the setter.
on_cell_in_b_only	**Signature**: *[signal]* void **on_cell_in_b_only** (const Cell ptr c) **Description**: This signal indicates that the given cell is only present in the second layout **Python specific notes:** The object exposes a readable attribute 'on_cell_in_b_only'. This is the getter. The object exposes a writable attribute 'on_cell_in_b_only'. This is the setter.

on_cell_meta_info_differs

Signature: *[signal]* void **on_cell_meta_info_differs** (string name, variant a, variant b)

Description: This signal indicates that meta info between the current cells differs

Meta information is only compared when WithMetaInfo is added to the compare flags. 'a' and 'b' are the values for the first and second layout. 'nil' is passed to these values to indicate missing meta information on one side.

This event has been added in version 0.28.16.

Python specific notes:
The object exposes a readable attribute 'on_cell_meta_info_differs'. This is the getter.
The object exposes a writable attribute 'on_cell_meta_info_differs'. This is the setter.

on_cell_name_differs

Signature: *[signal]* void **on_cell_name_differs** (const Cell ptr ca, const Cell ptr cb)

Description: This signal indicates a difference in the cell names

This signal is emitted in 'smart cell mapping' mode (see SmartCellMapping) if two cells are considered identical, but have different names.

Python specific notes:
The object exposes a readable attribute 'on_cell_name_differs'. This is the getter.
The object exposes a writable attribute 'on_cell_name_differs'. This is the setter.

on_dbu_differs

Signature: *[signal]* void **on_dbu_differs** (double dbu_a, double dbu_b)

Description: This signal indicates a difference in the database units of the layouts

Python specific notes:
The object exposes a readable attribute 'on_dbu_differs'. This is the getter.
The object exposes a writable attribute 'on_dbu_differs'. This is the setter.

on_edge_in_a_only

Signature: *[signal]* void **on_edge_in_a_only** (const Edge anotb, unsigned long prop_id)

Description: This signal indicates an edge that is present in the first layout only

Python specific notes:
The object exposes a readable attribute 'on_edge_in_a_only'. This is the getter.
The object exposes a writable attribute 'on_edge_in_a_only'. This is the setter.

on_edge_in_b_only

Signature: *[signal]* void **on_edge_in_b_only** (const Edge bnota, unsigned long prop_id)

Description: This signal indicates an edge that is present in the second layout only

Python specific notes:
The object exposes a readable attribute 'on_edge_in_b_only'. This is the getter.
The object exposes a writable attribute 'on_edge_in_b_only'. This is the setter.

on_edge_pair_in_a_only

Signature: *[signal]* void **on_edge_pair_in_a_only** (const EdgePair anotb, unsigned long prop_id)

Description: This signal indicates an edge pair that is present in the first layout only

This event has been introduced in version 0.28.

Python specific notes:
The object exposes a readable attribute 'on_edge_pair_in_a_only'. This is the getter.
The object exposes a writable attribute 'on_edge_pair_in_a_only'. This is the setter.

on_edge_pair_in_b_only

Signature: *[signal]* void **on_edge_pair_in_b_only** (const EdgePair bnota, unsigned long prop_id)

Description: This signal indicates an edge pair that is present in the second layout only

This event has been introduced in version 0.28.

Python specific notes:
The object exposes a readable attribute 'on_edge_pair_in_b_only'. This is the getter.
The object exposes a writable attribute 'on_edge_pair_in_b_only'. This is the setter.

on_end_box_differences

Signature: *[signal]* void **on_end_box_differences**

Description: This signal indicates the end of sequence of box differences

Python specific notes:
The object exposes a readable attribute 'on_end_box_differences'. This is the getter.
The object exposes a writable attribute 'on_end_box_differences'. This is the setter.

on_end_cell

Signature: *[signal]* void **on_end_cell**

Description: This signal indicates the end of a sequence of signals for a specific cell

Python specific notes:
The object exposes a readable attribute 'on_end_cell'. This is the getter.
The object exposes a writable attribute 'on_end_cell'. This is the setter.

on_end_edge_differences

Signature: *[signal]* void **on_end_edge_differences**

Description: This signal indicates the end of sequence of edge differences

Python specific notes:
The object exposes a readable attribute 'on_end_edge_differences'. This is the getter.
The object exposes a writable attribute 'on_end_edge_differences'. This is the setter.

on_end_edge_pair_differences

Signature: *[signal]* void **on_end_edge_pair_differences**

Description: This signal indicates the end of sequence of edge pair differences

This event has been introduced in version 0.28.

Python specific notes:
The object exposes a readable attribute 'on_end_edge_pair_differences'. This is the getter.
The object exposes a writable attribute 'on_end_edge_pair_differences'. This is the setter.

on_end_inst_differences

Signature: *[signal]* void **on_end_inst_differences**

Description: This signal finishes a sequence of detailed instance difference events

Python specific notes:
The object exposes a readable attribute 'on_end_inst_differences'. This is the getter.
The object exposes a writable attribute 'on_end_inst_differences'. This is the setter.

on_end_layer

Signature: *[signal]* void **on_end_layer**

Description: This signal indicates the end of a sequence of signals for a specific layer

Python specific notes:
The object exposes a readable attribute 'on_end_layer'. This is the getter.
The object exposes a writable attribute 'on_end_layer'. This is the setter.

on_end_path_differences

Signature: *[signal]* void **on_end_path_differences**

Description: This signal indicates the end of sequence of path differences

Python specific notes:
The object exposes a readable attribute 'on_end_path_differences'. This is the getter.
The object exposes a writable attribute 'on_end_path_differences'. This is the setter.

on_end_polygon_differences

Signature: *[signal]* void **on_end_polygon_differences**

Description: This signal indicates the end of sequence of polygon differences

Python specific notes:
The object exposes a readable attribute 'on_end_polygon_differences'. This is the getter.
The object exposes a writable attribute 'on_end_polygon_differences'. This is the setter.

on_end_text_differences

Signature: *[signal]* void **on_end_text_differences**

Description: This signal indicates the end of sequence of text differences

Python specific notes:
The object exposes a readable attribute 'on_end_text_differences'. This is the getter.
The object exposes a writable attribute 'on_end_text_differences'. This is the setter.

on_instance_in_a_only

Signature: *[signal]* void **on_instance_in_a_only** (const CellInstArray anotb, unsigned long prop_id)

Description: This signal indicates an instance that is present only in the first layout

This event is only emitted in verbose mode (Verbose flag).

Python specific notes:
The object exposes a readable attribute 'on_instance_in_a_only'. This is the getter.
The object exposes a writable attribute 'on_instance_in_a_only'. This is the setter.

on_instance_in_b_only

Signature: *[signal]* void **on_instance_in_b_only** (const CellInstArray bnota, unsigned long prop_id)

Description: This signal indicates an instance that is present only in the second layout

This event is only emitted in verbose mode (Verbose flag).

Python specific notes:
The object exposes a readable attribute 'on_instance_in_b_only'. This is the getter.
The object exposes a writable attribute 'on_instance_in_b_only'. This is the setter.

on_layer_in_a_only

Signature: *[signal]* void **on_layer_in_a_only** (const LayerInfo a)

Description: This signal indicates a layer that is present only in the first layout

Python specific notes:
The object exposes a readable attribute 'on_layer_in_a_only'. This is the getter.
The object exposes a writable attribute 'on_layer_in_a_only'. This is the setter.

on_layer_in_b_only

Signature: *[signal]* void **on_layer_in_b_only** (const LayerInfo b)

Description: This signal indicates a layer that is present only in the second layout

Python specific notes:
The object exposes a readable attribute 'on_layer_in_b_only'. This is the getter.
The object exposes a writable attribute 'on_layer_in_b_only'. This is the setter.

on_layer_name_differs

Signature: *[signal]* void **on_layer_name_differs** (const LayerInfo a, const LayerInfo b)

Description: This signal indicates a difference in the layer names

Python specific notes:
The object exposes a readable attribute 'on_layer_name_differs'. This is the getter.
The object exposes a writable attribute 'on_layer_name_differs'. This is the setter.

on_layout_meta_info_differs

Signature: *[signal]* void **on_layout_meta_info_differs** (string name, variant a, variant b)

Description: This signal indicates that global meta info differs

	Meta information is only compared when WithMetaInfo is added to the compare flags. 'a' and 'b' are the values for the first and second layout. 'nil' is passed to these values to indicate missing meta information on one side. This event has been added in version 0.28.16. **Python specific notes:** The object exposes a readable attribute 'on_layout_meta_info_differs'. This is the getter. The object exposes a writable attribute 'on_layout_meta_info_differs'. This is the setter.
on_path_in_a_only	**Signature**: *[signal]* void **on_path_in_a_only** (const Path anotb, unsigned long prop_id) **Description**: This signal indicates a path that is present in the first layout only **Python specific notes:** The object exposes a readable attribute 'on_path_in_a_only'. This is the getter. The object exposes a writable attribute 'on_path_in_a_only'. This is the setter.
on_path_in_b_only	**Signature**: *[signal]* void **on_path_in_b_only** (const Path bnota, unsigned long prop_id) **Description**: This signal indicates a path that is present in the second layout only **Python specific notes:** The object exposes a readable attribute 'on_path_in_b_only'. This is the getter. The object exposes a writable attribute 'on_path_in_b_only'. This is the setter.
on_per_layer_bbox_differs	**Signature**: *[signal]* void **on_per_layer_bbox_differs** (const Box ba, const Box bb) **Description**: This signal indicates differences in the per-layer bounding boxes of the current cell **Python specific notes:** The object exposes a readable attribute 'on_per_layer_bbox_differs'. This is the getter. The object exposes a writable attribute 'on_per_layer_bbox_differs'. This is the setter.
on_polygon_in_a_only	**Signature**: *[signal]* void **on_polygon_in_a_only** (const Polygon anotb, unsigned long prop_id) **Description**: This signal indicates a polygon that is present in the first layout only **Python specific notes:** The object exposes a readable attribute 'on_polygon_in_a_only'. This is the getter. The object exposes a writable attribute 'on_polygon_in_a_only'. This is the setter.
on_polygon_in_b_only	**Signature**: *[signal]* void **on_polygon_in_b_only** (const Polygon bnota, unsigned long prop_id) **Description**: This signal indicates a polygon that is present in the second layout only **Python specific notes:** The object exposes a readable attribute 'on_polygon_in_b_only'. This is the getter. The object exposes a writable attribute 'on_polygon_in_b_only'. This is the setter.
on_text_in_a_only	**Signature**: *[signal]* void **on_text_in_a_only** (const Text anotb, unsigned long prop_id) **Description**: This signal indicates a text that is present in the first layout only **Python specific notes:** The object exposes a readable attribute 'on_text_in_a_only'. This is the getter. The object exposes a writable attribute 'on_text_in_a_only'. This is the setter.
on_text_in_b_only	**Signature**: *[signal]* void **on_text_in_b_only** (const Text bnota, unsigned long prop_id) **Description**: This signal indicates a text that is present in the second layout only **Python specific notes:** The object exposes a readable attribute 'on_text_in_b_only'. This is the getter.

The object exposes a writable attribute 'on_text_in_b_only'. This is the setter.

4.115. API reference - Class TextGenerator

Notation used in Ruby API documentation

Module: db

Description: A text generator class

A text generator is basically a way to produce human-readable text for labelling layouts. It's similar to the Basic.TEXT PCell, but more convenient to use in a scripting context.

Generators can be constructed from font files (or resources) or one of the registered generators can be used.

To create a generator from a font file proceed this way:

```
gen = RBA::TextGenerator::new
gen.load_from_file("myfont.gds")
region = gen.text("A TEXT", 0.001)
```

This code produces a RBA::Region with a database unit of 0.001 micron. This region can be fed into a Shapes container to place it into a cell for example.

By convention the font files must have two to three layers:

- 1/0 for the actual data
- 2/0 for the borders
- 3/0 for an optional additional background

Currently, all glyphs must be bottom-left aligned at 0, 0. The border must be drawn in at least one glyph cell. The border is taken as the overall bbox of all borders.

The glyph cells must be named with a single character or "nnn" where "d" is the ASCII code of the character (i.e. "032" for space). Allowed ASCII codes are 32 through 127. If a lower-case "a" character is defined, lower-case letters are supported. Otherwise, lowercase letters are mapped to uppercase letters.

Undefined characters are left blank in the output.

A comment cell can be defined ("COMMENT") which must hold one text in layer 1 stating the comment, and additional descriptions such as line width:

- "line_width=<x>": Specifies the intended line width in micron units
- "design_grid=<x>": Specifies the intended design grid in micron units
- any other text: The description string

Generators can be picked form a list of predefined generator. See generators, default_generator and generator_by_name for picking a generator from the list.

This class has been introduced in version 0.25.

Public constructors

new TextGenerator ptr	**new**	Creates a new object of this class

Public methods

void	**_create**	Ensures the C++ object is created
void	**_destroy**	Explicitly destroys the object

[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const TextGenerato other)	Assigns another object to self
[const]	Box	**background**		Gets the background rectangle of each glyph in the generator's database units
[const]	DBox	**dbackground**		Gets the background rectangle in micron units
[const]	double	**dbu**		Gets the basic database unit the design of the glyphs was made
[const]	double	**ddesign_grid**		Gets the design grid of the glyphs in micron units
[const]	string	**description**		Gets the description text of the generator
[const]	int	**design_grid**		Gets the design grid of the glyphs in the generator's database units
[const]	double	**dheight**		Gets the design height of the glyphs in micron units
[const]	double	**dline_width**		Gets the line width of the glyphs in micron units
[const]	new TextGenerator ptr	**dup**		Creates a copy of self
[const]	double	**dwidth**		Gets the design width of the glyphs in micron units
[const]	Region	**glyph**	(char char)	Gets the glyph of the given character as a region
[const]	int	**height**		Gets the design height of the glyphs in the generator's database units
[const]	int	**line_width**		Gets the line width of the glyphs in the generator's database units
	void	**load_from_file**	(string path)	Loads the given file into the generator
	void	**load_from_resource**	(string resource_path)	Loads the given resource data (as layout data) into the generator
[const]	string	**name**		Gets the name of the generator
[const]	Region	**text**	(string text, double target_dbu,	Gets the rendered text as a region

			double mag = 1, bool inv = false, double bias = 0, double char_spacing = 0, double line_spacing = 0)	
[const]	int	**width**		Gets the design height of the glyphs in the generator's database units

Public static methods and constants

	const TextGenerator ptr	**default_generator**		Gets the default text generator (a standard font)
	string[]	**font_paths**		Gets the paths where to look for font files
	const TextGenerator ptr	**generator_by_name**	(string name)	Gets the text generator for a given name
	const TextGenerator ptr[]	**generators**		Gets the generators registered in the system
	void	**set_font_paths**	(string[] paths)	Sets the paths where to look for font files

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const TextGenerator other)

Description: Assigns another object to self

background

Signature: *[const]* Box **background**

Description: Gets the background rectangle of each glyph in the generator's database units

The background rectangle is the one that is used as background for inverted rendering. A version that delivers this value in micrometer units is dbackground.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

dbackground

Signature: *[const]* DBox **dbackground**

Description: Gets the background rectangle in micron units

The background rectangle is the one that is used as background for inverted rendering.

dbu

Signature: *[const]* double **dbu**

Description: Gets the basic database unit the design of the glyphs was made

This database unit the basic resolution of the glyphs.

ddesign_grid

Signature: *[const]* double **ddesign_grid**

Description: Gets the design grid of the glyphs in micron units

The design grid is the basic grid used when designing the glyphs. In most cases this grid is bigger than the database unit.

default_generator

Signature: *[static]* const TextGenerator ptr **default_generator**

Description: Gets the default text generator (a standard font)

This method delivers the default generator or nil if no such generator is installed.

description

Signature: *[const]* string **description**

Description: Gets the description text of the generator

The generator's description text is a human-readable text that is used to identify the generator (aka 'font') in user interfaces.

design_grid

Signature: *[const]* int **design_grid**

Description: Gets the design grid of the glyphs in the generator's database units

The design grid is the basic grid used when designing the glyphs. In most cases this grid is bigger than the database unit. A version that delivers this value in micrometer units is ddesign_grid.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dheight

Signature: *[const]* double **dheight**

Description: Gets the design height of the glyphs in micron units

The height is the height of the rectangle occupied by each character.

dline_width

Signature: *[const]* double **dline_width**

Description: Gets the line width of the glyphs in micron units

The line width is the intended (not necessarily precisely) line width of typical character lines (such as the bar of an 'I').

dup

Signature: *[const]* new TextGenerator ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

dwidth

Signature: *[const]* double **dwidth**

Description: Gets the design width of the glyphs in micron units

The width is the width of the rectangle occupied by each character.

font_paths

Signature: *[static]* string[] **font_paths**

Description: Gets the paths where to look for font files

See set_font_paths for a description of this function.

This method has been introduced in version 0.27.4.

generator_by_name

Signature: *[static]* const TextGenerator ptr **generator_by_name** (string name)

Description: Gets the text generator for a given name

This method delivers the generator with the given name or nil if no such generator is registered.

generators

Signature: *[static]* const TextGenerator ptr[] **generators**

Description: Gets the generators registered in the system

This method delivers a list of generator objects that can be used to create texts.

glyph

Signature: *[const]* Region **glyph** (char char)

Description: Gets the glyph of the given character as a region

The region represents the glyph's outline and is delivered in the generator's database units .A more elaborate way to getting the text's outline is text.

height

Signature: *[const]* int **height**

Description: Gets the design height of the glyphs in the generator's database units

The height is the height of the rectangle occupied by each character. A version that delivers this value in micrometer units is dheight.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

line_width

Signature: *[const]* int **line_width**

Description: Gets the line width of the glyphs in the generator's database units

The line width is the intended (not necessarily precisely) line width of typical character lines (such as the bar of an 'I'). A version that delivers this value in micrometer units is dline_width.

load_from_file

Signature: void **load_from_file** (string path)

Description: Loads the given file into the generator

See the description of the class how the layout data is read.

load_from_resource

Signature: void **load_from_resource** (string resource_path)

Description: Loads the given resource data (as layout data) into the generator

The resource path has to start with a colon, i.e. ':/my/resource.gds'. See the description of the class how the layout data is read.

name

Signature: *[const]* string **name**

Description: Gets the name of the generator

The generator's name is the basic key by which the generator is identified.

new

Signature: *[static]* new TextGenerator ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

set_font_paths

Signature: *[static]* void **set_font_paths** (string[] paths)

Description: Sets the paths where to look for font files

This function sets the paths where to look for font files. After setting such a path, each font found will render a specific generator. The generator can be found under the font file's name. As the text generator is also the basis for the Basic.TEXT PCell, using this function also allows configuring custom fonts for this library cell.

This method has been introduced in version 0.27.4.

text

Signature: *[const]* Region **text** (string text, double target_dbu, double mag = 1, bool inv = false, double bias = 0, double char_spacing = 0, double line_spacing = 0)

Description: Gets the rendered text as a region

text:	The text string
target_dbu:	The database unit for which to produce the text
mag:	The magnification (1.0 for original size)
inv:	inverted rendering: if true, the glyphs are rendered inverse with the background box as the outer bounding box
bias:	An additional bias to be applied (happens before inversion, can be negative)
char_spacing:	Additional space between characters (in micron units)
line_spacing:	Additional space between lines (in micron units)

Various options can be specified to control the appearance of the text. See the description of the parameters. It's important to specify the target database unit in target_dbu to indicate what database unit shall be used to create the output for.

width

Signature: *[const]* int **width**

Description: Gets the design height of the glyphs in the generator's database units

The width is the width of the rectangle occupied by each character. A version that delivers this value in micrometer units is dwidth.

4.116. API reference - Class NetlistObject

Notation used in Ruby API documentation

Module: db

Description: The base class for some netlist objects.

The main purpose of this class is to supply user properties for netlist objects.

This class has been introduced in version 0.26.2

Public constructors

new NetlistObject ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const NetlistObject other)	Assigns another object to self
[const]	new NetlistObject ptr	**dup**		Creates a copy of self
[const]	variant	**property**	(variant key)	Gets the property value for the given key or nil if there is no value with this key.
[const]	variant[]	**property_keys**		Gets the keys for the properties stored in this object.
	void	**set_property**	(variant key, variant value)	Sets the property value for the given key.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead

[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const NetlistObject other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new NetlistObject ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new NetlistObject ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

property

Signature: *[const]* variant **property** (variant key)

Description: Gets the property value for the given key or nil if there is no value with this key.

property_keys

Signature: *[const]* variant[] **property_keys**

Description: Gets the keys for the properties stored in this object.

set_property

Signature: void **set_property** (variant key, variant value)

Description: Sets the property value for the given key.

Use a nil value to erase the property with this key.

4.117. API reference - Class Pin

Notation used in Ruby API documentation

Module: db

Description: A pin of a circuit.

Class hierarchy: Pin » NetlistObject

Pin objects are used to describe the outgoing pins of a circuit. To create a new pin of a circuit, use Circuit#create_pin.

This class has been added in version 0.26.

Public methods

	void	**_assign**	(const Pin other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new Pin ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	string	**expanded_name**		Gets the expanded name of the pin.
[const]	unsigned long	**id**		Gets the ID of the pin.
[const]	string	**name**		Gets the name of the pin.

Detailed description

_assign

Signature: void **_assign** (const Pin other)

Description: Assigns another object to self

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

	Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
_destroyed?	**Signature**: *[const]* bool **_destroyed?** **Description**: Returns a value indicating whether the object was already destroyed This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
_dup	**Signature**: *[const]* new Pin ptr **_dup** **Description**: Creates a copy of self
_is_const_object?	**Signature**: *[const]* bool **_is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference This method returns true, if self is a const reference. In that case, only const methods may be called on self.
_manage	**Signature**: void **_manage** **Description**: Marks the object as managed by the script side. After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required. Usually it's not required to call this method. It has been introduced in version 0.24.
_unmanage	**Signature**: void **_unmanage** **Description**: Marks the object as no longer owned by the script side. Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.
expanded_name	**Signature**: *[const]* string **expanded_name** **Description**: Gets the expanded name of the pin. The expanded name is the name or a generic identifier made from the ID if the name is empty.
id	**Signature**: *[const]* unsigned long **id** **Description**: Gets the ID of the pin.
name	**Signature**: *[const]* string **name** **Description**: Gets the name of the pin.

4.118. API reference - Class DeviceReconnectedTerminal

Notation used in Ruby API documentation

Module: db

Description: Describes a terminal rerouting in combined devices.

Combined devices are implemented as a generalization of the device abstract concept in Device. For combined devices, multiple DeviceAbstract references are present. To support different combination schemes, device-to-abstract routing is supported. Parallel combinations will route all outer terminals to corresponding terminals of all device abstracts (because of terminal swapping these may be different ones).

This object describes one route to an abstract's terminal. The device index is 0 for the main device abstract and 1 for the first combined device abstract.

This class has been introduced in version 0.26.

Public constructors

new DeviceReconnectedTerminal ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const DeviceReconne other)	Assigns another object to self
[const]	unsigned long	**device_index**		The device abstract index getter.
	void	**device_index=**	(unsigned long device_index)	The device abstract index setter.
[const]	new DeviceReconnectedTerminal ptr	**dup**		Creates a copy of self
[const]	unsigned long	**other_terminal_id**		The getter for the abstract's connected terminal.
	void	**other_terminal_id=**	(unsigned int other_terminal_id)	The setter for the abstract's connected terminal.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method

will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const DeviceReconnectedTerminal other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

device_index

Signature: *[const]* unsigned long **device_index**

Description: The device abstract index getter.

See the class description for details.

Python specific notes:
The object exposes a readable attribute 'device_index'. This is the getter.

device_index=

Signature: void **device_index=** (unsigned long device_index)

Description: The device abstract index setter.

See the class description for details.

Python specific notes:
The object exposes a writable attribute 'device_index'. This is the setter.

dup

Signature: *[const]* new DeviceReconnectedTerminal ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

	Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.
new	**Signature**: *[static]* new DeviceReconnectedTerminal ptr **new** **Description**: Creates a new object of this class **Python specific notes:** This method is the default initializer of the object.
other_terminal_id	**Signature**: *[const]* unsigned long **other_terminal_id** **Description**: The getter for the abstract's connected terminal. See the class description for details. **Python specific notes:** The object exposes a readable attribute 'other_terminal_id'. This is the getter.
other_terminal_id=	**Signature**: void **other_terminal_id=** (unsigned int other_terminal_id) **Description**: The setter for the abstract's connected terminal. See the class description for details. **Python specific notes:** The object exposes a writable attribute 'other_terminal_id'. This is the setter.

4.119. API reference - Class DeviceAbstractRef

Notation used in Ruby API documentation

Module: db

Description: Describes an additional device abstract reference for combined devices.

Combined devices are implemented as a generalization of the device abstract concept in Device. For combined devices, multiple DeviceAbstract references are present. This class describes such an additional reference. A reference is a pointer to an abstract plus a transformation by which the abstract is transformed geometrically as compared to the first (initial) abstract.

This class has been introduced in version 0.26.

Public constructors

new DeviceAbstractRef ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const DeviceAbstract other)	Assigns another object to self
[const]	const DeviceAbstract ptr	**device_abstract**		The getter for the device abstract reference.
	void	**device_abstract=**	(const DeviceAbstract ptr device_abstrac	The setter for the device abstract reference.
[const]	new DeviceAbstractRef ptr	**dup**		Creates a copy of self
[const]	DCplxTrans	**trans**		The getter for the relative transformation of the instance.
	void	**trans=**	(const DCplxTrans tr)	The setter for the relative transformation of the instance.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method

will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const DeviceAbstractRef other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

device_abstract

Signature: *[const]* const DeviceAbstract ptr **device_abstract**

Description: The getter for the device abstract reference.

See the class description for details.

Python specific notes:
The object exposes a readable attribute 'device_abstract'. This is the getter.

device_abstract=

Signature: void **device_abstract=** (const DeviceAbstract ptr device_abstract)

Description: The setter for the device abstract reference.

See the class description for details.

Python specific notes:
The object exposes a writable attribute 'device_abstract'. This is the setter.

dup

Signature: *[const]* new DeviceAbstractRef ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new DeviceAbstractRef ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

trans

Signature: *[const]* DCplxTrans **trans**

Description: The getter for the relative transformation of the instance.

See the class description for details.

Python specific notes:
The object exposes a readable attribute 'trans'. This is the getter.

trans=

Signature: void **trans=** (const DCplxTrans tr)

Description: The setter for the relative transformation of the instance.

See the class description for details.

Python specific notes:
The object exposes a writable attribute 'trans'. This is the setter.

4.120. API reference - Class Device

Notation used in Ruby API documentation

Module: db

Description: A device inside a circuit.

Class hierarchy: Device » NetlistObject

Device object represent atomic devices such as resistors, diodes or transistors. The Device class represents a particular device with specific parameters. The type of device is represented by a DeviceClass object. Device objects live in Circuit objects, the device class objects live in the Netlist object.

Devices connect to nets through terminals. Terminals are described by a terminal ID which is essentially the zero-based index of the terminal. Terminal definitions can be obtained from the device class using the DeviceClass#terminal_definitions method.

Devices connect to nets through the Device#connect_terminal method. Device terminals can be disconnected using Device#disconnect_terminal.

Device objects are created inside a circuit with Circuit#create_device.

This class has been added in version 0.26.

Public methods

	void	**_assign**	(const Device other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new Device ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	const Circuit ptr	**circuit**		Gets the circuit the device lives in.
	Circuit ptr	**circuit**		Gets the circuit the device lives in (non-const version).
	void	**connect_terminal**	(unsigned long terminal_id, Net ptr net)	Connects the given terminal to the specified net.
	void	**connect_terminal**	(string terminal_name, Net ptr net)	Connects the given terminal to the specified net.
[const]	const DeviceAbstract ptr	**device_abstract**		Gets the device abstract for this device instance.

[const]	const DeviceClass ptr	**device_class**		Gets the device class the device belongs to.
	void	**disconnect_terminal**	(unsigned long terminal_id)	Disconnects the given terminal from any net.
	void	**disconnect_terminal**	(string terminal_name)	Disconnects the given terminal from any net.
[const,iter]	DeviceAbstractRef	**each_combined_abstra**		Iterates over the combined device specifications.
[const,iter]	DeviceReconnectedTerminal	**each_reconnected_terminal_for**	(unsigned long terminal_id)	Iterates over the reconnected terminal specifications for a given outer terminal.
[const]	string	**expanded_name**		Gets the expanded name of the device.
[const]	unsigned long	**id**		Gets the device ID.
[const]	bool	**is_combined_device?**		Returns true, if the device is a combined device.
[const]	string	**name**		Gets the name of the device.
	void	**name=**	(string name)	Sets the name of the device.
[const]	const Net ptr	**net_for_terminal**	(unsigned long terminal_id)	Gets the net connected to the specified terminal.
	Net ptr	**net_for_terminal**	(unsigned long terminal_id)	Gets the net connected to the specified terminal (non-const version).
[const]	const Net ptr	**net_for_terminal**	(string terminal_name)	Gets the net connected to the specified terminal.
	Net ptr	**net_for_terminal**	(string terminal_name)	Gets the net connected to the specified terminal (non-const version).
[const]	double	**parameter**	(unsigned long param_id)	Gets the parameter value for the given parameter ID.
[const]	double	**parameter**	(string param_name)	Gets the parameter value for the given parameter name.
	void	**set_parameter**	(unsigned long param_id, double value)	Sets the parameter value for the given parameter ID.
	void	**set_parameter**	(string param_name, double value)	Sets the parameter value for the given parameter name.
[const]	DCplxTrans	**trans**		Gets the location of the device.
	void	**trans=**	(const DCplxTrans t)	Sets the location of the device.

Detailed description

_assign	**Signature**: void **_assign** (const Device other) **Description**: Assigns another object to self
_create	**Signature**: void **_create** **Description**: Ensures the C++ object is created Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
_destroy	**Signature**: void **_destroy** **Description**: Explicitly destroys the object Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
_destroyed?	**Signature**: *[const]* bool **_destroyed?** **Description**: Returns a value indicating whether the object was already destroyed This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
_dup	**Signature**: *[const]* new Device ptr **_dup** **Description**: Creates a copy of self
_is_const_object?	**Signature**: *[const]* bool **_is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference This method returns true, if self is a const reference. In that case, only const methods may be called on self.
_manage	**Signature**: void **_manage** **Description**: Marks the object as managed by the script side. After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required. Usually it's not required to call this method. It has been introduced in version 0.24.
_unmanage	**Signature**: void **_unmanage** **Description**: Marks the object as no longer owned by the script side. Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.

circuit

(1) Signature: *[const]* const Circuit ptr **circuit**

Description: Gets the circuit the device lives in.

(2) Signature: Circuit ptr **circuit**

Description: Gets the circuit the device lives in (non-const version).

This constness variant has been introduced in version 0.26.8

connect_terminal

(1) Signature: void **connect_terminal** (unsigned long terminal_id, Net ptr net)

Description: Connects the given terminal to the specified net.

(2) Signature: void **connect_terminal** (string terminal_name, Net ptr net)

Description: Connects the given terminal to the specified net.

This version accepts a terminal name. If the name is not a valid terminal name, an exception is raised. If the terminal has been connected to a global net, it will be disconnected from there.

device_abstract

Signature: *[const]* const DeviceAbstract ptr **device_abstract**

Description: Gets the device abstract for this device instance.

See DeviceAbstract for more details.

Python specific notes:
The object exposes a readable attribute 'device_abstract'. This is the getter.

device_class

Signature: *[const]* const DeviceClass ptr **device_class**

Description: Gets the device class the device belongs to.

disconnect_terminal

(1) Signature: void **disconnect_terminal** (unsigned long terminal_id)

Description: Disconnects the given terminal from any net.

If the terminal has been connected to a global, this connection will be disconnected too.

(2) Signature: void **disconnect_terminal** (string terminal_name)

Description: Disconnects the given terminal from any net.

This version accepts a terminal name. If the name is not a valid terminal name, an exception is raised.

each_combined_abstract

Signature: *[const,iter]* DeviceAbstractRef **each_combined_abstract**

Description: Iterates over the combined device specifications.

This feature applies to combined devices. This iterator will deliver all device abstracts present in addition to the default device abstract.

each_reconnected_terminal_f

Signature: *[const,iter]* DeviceReconnectedTerminal **each_reconnected_terminal_for** (unsigned long terminal_id)

Description: Iterates over the reconnected terminal specifications for a given outer terminal.

This feature applies to combined devices. This iterator will deliver all device-to-abstract terminal reroutings.

expanded_name

Signature: *[const]* string **expanded_name**

Description: Gets the expanded name of the device.

The expanded name takes the name of the device. If the name is empty, the numeric ID will be used to build a name.

id

Signature: *[const]* unsigned long **id**

Description: Gets the device ID.

The ID is a unique integer which identifies the device. It can be used to retrieve the device from the circuit using Circuit#device_by_id. When assigned, the device ID is not 0.

is_combined_device?

Signature: *[const]* bool **is_combined_device?**

Description: Returns true, if the device is a combined device.

Combined devices feature multiple device abstracts and device-to-abstract terminal connections. See each_reconnected_terminal and each_combined_abstract for more details.

name

Signature: *[const]* string **name**

Description: Gets the name of the device.

Python specific notes:
The object exposes a readable attribute 'name'. This is the getter.

name=

Signature: void **name=** (string name)

Description: Sets the name of the device.

Device names are used to name a device inside a netlist file. Device names should be unique within a circuit.

Python specific notes:
The object exposes a writable attribute 'name'. This is the setter.

net_for_terminal

(1) Signature: *[const]* const Net ptr **net_for_terminal** (unsigned long terminal_id)

Description: Gets the net connected to the specified terminal.

If the terminal is not connected, nil is returned for the net.

(2) Signature: Net ptr **net_for_terminal** (unsigned long terminal_id)

Description: Gets the net connected to the specified terminal (non-const version).

If the terminal is not connected, nil is returned for the net.

This constness variant has been introduced in version 0.26.8

(3) Signature: *[const]* const Net ptr **net_for_terminal** (string terminal_name)

Description: Gets the net connected to the specified terminal.

If the terminal is not connected, nil is returned for the net.

This convenience method has been introduced in version 0.27.3.

(4) Signature: Net ptr **net_for_terminal** (string terminal_name)

Description: Gets the net connected to the specified terminal (non-const version).

If the terminal is not connected, nil is returned for the net.

	This convenience method has been introduced in version 0.27.3.
parameter	**(1) Signature**: *[const]* double **parameter** (unsigned long param_id) **Description**: Gets the parameter value for the given parameter ID. **(2) Signature**: *[const]* double **parameter** (string param_name) **Description**: Gets the parameter value for the given parameter name. If the parameter name is not valid, an exception is thrown.
set_parameter	**(1) Signature**: void **set_parameter** (unsigned long param_id, double value) **Description**: Sets the parameter value for the given parameter ID. **(2) Signature**: void **set_parameter** (string param_name, double value) **Description**: Sets the parameter value for the given parameter name. If the parameter name is not valid, an exception is thrown.
trans	**Signature**: *[const]* DCplxTrans **trans** **Description**: Gets the location of the device. See trans= for details about this method. **Python specific notes:** The object exposes a readable attribute 'trans'. This is the getter.
trans=	**Signature**: void **trans=** (const DCplxTrans t) **Description**: Sets the location of the device. The device location is essentially describing the position of the device. The position is typically the center of some recognition shape. In this case the transformation is a plain displacement to the center of this shape. **Python specific notes:** The object exposes a writable attribute 'trans'. This is the setter.

4.121. API reference - Class DeviceAbstract

Notation used in Ruby API documentation

Module: db

Description: A geometrical device abstract

This class represents the geometrical model for the device. It links into the extracted layout to a cell which holds the terminal shapes for the device.

This class has been added in version 0.26.

Public constructors

new DeviceAbstract ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const DeviceAbstra other)	Assigns another object to self
[const]	unsigned int	**cell_index**		Gets the cell index of the device abstract.
[const]	unsigned long	**cluster_id_for_termina**	(unsigned long terminal_id)	Gets the cluster ID for the given terminal.
[const]	const DeviceClass ptr	**device_class**		Gets the device class of the device.
[const]	new DeviceAbstract ptr	**dup**		Creates a copy of self
[const]	string	**name**		Gets the name of the device abstract.
	void	**name=**	(string name)	Sets the name of the device abstract.
[const]	const Netlist ptr	**netlist**		Gets the netlist the device abstract lives in.
	Netlist ptr	**netlist**		Gets the netlist the device abstract lives in (non-const version).

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method

	will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.
assign	**Signature**: void **assign** (const DeviceAbstract other) **Description**: Assigns another object to self
cell_index	**Signature**: *[const]* unsigned int **cell_index** **Description**: Gets the cell index of the device abstract. This is the cell that represents the device.
cluster_id_for_terminal	**Signature**: *[const]* unsigned long **cluster_id_for_terminal** (unsigned long terminal_id) **Description**: Gets the cluster ID for the given terminal. The cluster ID links the terminal to geometrical shapes within the clusters of the cell (see cell_index)
create	**Signature**: void **create** **Description**: Ensures the C++ object is created Use of this method is deprecated. Use _create instead Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
destroy	**Signature**: void **destroy** **Description**: Explicitly destroys the object Use of this method is deprecated. Use _destroy instead Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
destroyed?	**Signature**: *[const]* bool **destroyed?** **Description**: Returns a value indicating whether the object was already destroyed Use of this method is deprecated. Use _destroyed? instead This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
device_class	**Signature**: *[const]* const DeviceClass ptr **device_class** **Description**: Gets the device class of the device.
dup	**Signature**: *[const]* new DeviceAbstract ptr **dup** **Description**: Creates a copy of self **Python specific notes:** This method also implements '__copy__' and '__deepcopy__'.
is_const_object?	**Signature**: *[const]* bool **is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference

	Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.
name	**Signature**: *[const]* string **name** **Description**: Gets the name of the device abstract. **Python specific notes:** The object exposes a readable attribute 'name'. This is the getter.
name=	**Signature**: void **name=** (string name) **Description**: Sets the name of the device abstract. Device names are used to name a device abstract inside a netlist file. Device names should be unique within a netlist. **Python specific notes:** The object exposes a writable attribute 'name'. This is the setter.
netlist	**(1) Signature**: *[const]* const Netlist ptr **netlist** **Description**: Gets the netlist the device abstract lives in. **(2) Signature**: Netlist ptr **netlist** **Description**: Gets the netlist the device abstract lives in (non-const version). This constness variant has been introduced in version 0.26.8
new	**Signature**: *[static]* new DeviceAbstract ptr **new** **Description**: Creates a new object of this class **Python specific notes:** This method is the default initializer of the object.

4.122. API reference - Class SubCircuit

Notation used in Ruby API documentation

Module: db

Description: A subcircuit inside a circuit.

Class hierarchy: SubCircuit » NetlistObject

Circuits may instantiate other circuits as subcircuits similar to cells in layouts. Such an instance is a subcircuit. A subcircuit refers to a circuit implementation (a Circuit object), and presents connections through pins. The pins of a subcircuit can be connected to nets. The subcircuit pins are identical to the outgoing pins of the circuit the subcircuit refers to.

Subcircuits connect to nets through the SubCircuit#connect_pin method. SubCircuit pins can be disconnected using SubCircuit#disconnect_pin.

Subcircuit objects are created inside a circuit with Circuit#create_subcircuit.

This class has been added in version 0.26.

Public methods

	void	**_assign**	(const SubCircuit other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new SubCircuit ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	const Circuit ptr	**circuit**		Gets the circuit the subcircuit lives in.
	Circuit ptr	**circuit**		Gets the circuit the subcircuit lives in (non-const version).
[const]	const Circuit ptr	**circuit_ref**		Gets the circuit referenced by the subcircuit.
	Circuit ptr	**circuit_ref**		Gets the circuit referenced by the subcircuit (non-const version).
	void	**connect_pin**	(unsigned long pin_id, Net ptr net)	Connects the given pin to the specified net.
	void	**connect_pin**	(const Pin ptr pin, Net ptr net)	Connects the given pin to the specified net.

	void	**disconnect_pin**	(unsigned long pin_id)	Disconnects the given pin from any net.
	void	**disconnect_pin**	(const Pin ptr pin)	Disconnects the given pin from any net.
[const]	string	**expanded_name**		Gets the expanded name of the subcircuit.
[const]	unsigned long	**id**		Gets the subcircuit ID.
[const]	string	**name**		Gets the name of the subcircuit.
	void	**name=**	(string name)	Sets the name of the subcircuit.
[const]	const Net ptr	**net_for_pin**	(unsigned long pin_id)	Gets the net connected to the specified pin of the subcircuit.
	Net ptr	**net_for_pin**	(unsigned long pin_id)	Gets the net connected to the specified pin of the subcircuit (non-const version).
[const]	DCplxTrans	**trans**		Gets the physical transformation for the subcircuit.
	void	**trans=**	(const DCplxTrans trans)	Sets the physical transformation for the subcircuit.

Detailed description

_assign	**Signature**: void **_assign** (const SubCircuit other) **Description**: Assigns another object to self
_create	**Signature**: void **_create** **Description**: Ensures the C++ object is created Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
_destroy	**Signature**: void **_destroy** **Description**: Explicitly destroys the object Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
_destroyed?	**Signature**: *[const]* bool **_destroyed?** **Description**: Returns a value indicating whether the object was already destroyed This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
_dup	**Signature**: *[const]* new SubCircuit ptr **_dup** **Description**: Creates a copy of self

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

circuit

(1) Signature: *[const]* const Circuit ptr **circuit**

Description: Gets the circuit the subcircuit lives in.

This is NOT the circuit which is referenced. For getting the circuit that the subcircuit references, use circuit_ref.

(2) Signature: Circuit ptr **circuit**

Description: Gets the circuit the subcircuit lives in (non-const version).

This is NOT the circuit which is referenced. For getting the circuit that the subcircuit references, use circuit_ref.

This constness variant has been introduced in version 0.26.8

circuit_ref

(1) Signature: *[const]* const Circuit ptr **circuit_ref**

Description: Gets the circuit referenced by the subcircuit.

(2) Signature: Circuit ptr **circuit_ref**

Description: Gets the circuit referenced by the subcircuit (non-const version).

This constness variant has been introduced in version 0.26.8

connect_pin

(1) Signature: void **connect_pin** (unsigned long pin_id, Net ptr net)

Description: Connects the given pin to the specified net.

(2) Signature: void **connect_pin** (const Pin ptr pin, Net ptr net)

Description: Connects the given pin to the specified net.

	This version takes a Pin reference instead of a pin ID.
disconnect_pin	**(1) Signature**: void **disconnect_pin** (unsigned long pin_id) **Description**: Disconnects the given pin from any net. **(2) Signature**: void **disconnect_pin** (const Pin ptr pin) **Description**: Disconnects the given pin from any net. This version takes a Pin reference instead of a pin ID.
expanded_name	**Signature**: *[const]* string **expanded_name** **Description**: Gets the expanded name of the subcircuit. The expanded name takes the name of the subcircuit. If the name is empty, the numeric ID will be used to build a name.
id	**Signature**: *[const]* unsigned long **id** **Description**: Gets the subcircuit ID. The ID is a unique integer which identifies the subcircuit. It can be used to retrieve the subcircuit from the circuit using Circuit#subcircuit_by_id. When assigned, the subcircuit ID is not 0.
name	**Signature**: *[const]* string **name** **Description**: Gets the name of the subcircuit. **Python specific notes:** The object exposes a readable attribute 'name'. This is the getter.
name=	**Signature**: void **name=** (string name) **Description**: Sets the name of the subcircuit. SubCircuit names are used to name a subcircuits inside a netlist file. SubCircuit names should be unique within a circuit. **Python specific notes:** The object exposes a writable attribute 'name'. This is the setter.
net_for_pin	**(1) Signature**: *[const]* const Net ptr **net_for_pin** (unsigned long pin_id) **Description**: Gets the net connected to the specified pin of the subcircuit. If the pin is not connected, nil is returned for the net. **(2) Signature**: Net ptr **net_for_pin** (unsigned long pin_id) **Description**: Gets the net connected to the specified pin of the subcircuit (non-const version). If the pin is not connected, nil is returned for the net. This constness variant has been introduced in version 0.26.8
trans	**Signature**: *[const]* DCplxTrans **trans** **Description**: Gets the physical transformation for the subcircuit. This property applies to subcircuits derived from a layout. It specifies the placement of the respective cell. This property has been introduced in version 0.27.

Python specific notes:
The object exposes a readable attribute 'trans'. This is the getter.

trans=

Signature: void **trans=** (const DCplxTrans trans)

Description: Sets the physical transformation for the subcircuit.

See trans for details about this property.

This property has been introduced in version 0.27.

Python specific notes:
The object exposes a writable attribute 'trans'. This is the setter.

4.123. API reference - Class NetTerminalRef

Notation used in Ruby API documentation

Module: db

Description: A connection to a terminal of a device.

This object is used inside a net (see Net) to describe the connections a net makes.

This class has been added in version 0.26.

Public constructors

new NetTerminalRef ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const NetTerm other)	Assigns another object to self
[const]	const Device ptr	**device**		Gets the device reference.
	Device ptr	**device**		Gets the device reference (non-const version).
[const]	const DeviceClass ptr	**device_class**		Gets the class of the device which is addressed.
[const]	new NetTerminalRef ptr	**dup**		Creates a copy of self
[const]	const Net ptr	**net**		Gets the net this terminal reference is attached to.
	Net ptr	**net**		Gets the net this terminal reference is attached to (non-const version).
[const]	const DeviceTerminalDefinition ptr	**terminal_def**		Gets the terminal definition of the terminal that is connected
[const]	unsigned long	**terminal_id**		Gets the ID of the terminal of the device the connection is made to.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method

will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const NetTerminalRef other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

device

(1) Signature: *[const]* const Device ptr **device**

Description: Gets the device reference.

Gets the device object that this connection is made to.

(2) Signature: Device ptr **device**

Description: Gets the device reference (non-const version).

Gets the device object that this connection is made to.

This constness variant has been introduced in version 0.26.8

device_class

Signature: *[const]* const DeviceClass ptr **device_class**

Description: Gets the class of the device which is addressed.

dup

Signature: *[const]* new NetTerminalRef ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

is_const_object?	**Signature**: *[const]* bool **is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.
net	**(1) Signature**: *[const]* const Net ptr **net** **Description**: Gets the net this terminal reference is attached to. **(2) Signature**: Net ptr **net** **Description**: Gets the net this terminal reference is attached to (non-const version). This constness variant has been introduced in version 0.26.8
new	**Signature**: *[static]* new NetTerminalRef ptr **new** **Description**: Creates a new object of this class **Python specific notes:** This method is the default initializer of the object.
terminal_def	**Signature**: *[const]* const DeviceTerminalDefinition ptr **terminal_def** **Description**: Gets the terminal definition of the terminal that is connected
terminal_id	**Signature**: *[const]* unsigned long **terminal_id** **Description**: Gets the ID of the terminal of the device the connection is made to.

4.124. API reference - Class NetPinRef

Notation used in Ruby API documentation

Module: db

Description: A connection to an outgoing pin of the circuit.

This object is used inside a net (see Net) to describe the connections a net makes.

This class has been added in version 0.26.

Public constructors

new NetPinRef ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const NetPinR other)	Assigns another object to self
[const]	new NetPinRef ptr	**dup**		Creates a copy of self
[const]	const Net ptr	**net**		Gets the net this pin reference is attached to.
	Net ptr	**net**		Gets the net this pin reference is attached to (non-const version).
[const]	const Pin ptr	**pin**		Gets the Pin object of the pin the connection is made to.
[const]	unsigned long	**pin_id**		Gets the ID of the pin the connection is made to.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead

[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const NetPinRef other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new NetPinRef ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

net

(1) Signature: *[const]* const Net ptr **net**

Description: Gets the net this pin reference is attached to.

(2) Signature: Net ptr **net**

Description: Gets the net this pin reference is attached to (non-const version).

This constness variant has been introduced in version 0.26.8

new

Signature: *[static]* new NetPinRef ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

pin

Signature: *[const]* const Pin ptr **pin**

Description: Gets the Pin object of the pin the connection is made to.

pin_id

Signature: *[const]* unsigned long **pin_id**

Description: Gets the ID of the pin the connection is made to.

4.125. API reference - Class NetSubcircuitPinRef

Notation used in Ruby API documentation

Module: db

Description: A connection to a pin of a subcircuit.

This object is used inside a net (see Net) to describe the connections a net makes.

This class has been added in version 0.26.

Public constructors

new NetSubcircuitPinRef ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const NetSubci other)	Assigns another object to self
[const]	new NetSubcircuitPinRef ptr	**dup**		Creates a copy of self
[const]	const Net ptr	**net**		Gets the net this pin reference is attached to.
	Net ptr	**net**		Gets the net this pin reference is attached to (non-const version).
[const]	const Pin ptr	**pin**		Gets the Pin object of the pin the connection is made to.
[const]	unsigned long	**pin_id**		Gets the ID of the pin the connection is made to.
[const]	const SubCircuit ptr	**subcircuit**		Gets the subcircuit reference.
	SubCircuit ptr	**subcircuit**		Gets the subcircuit reference (non-const version).

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead

	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const NetSubcircuitPinRef other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new NetSubcircuitPinRef ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

net

(1) Signature: *[const]* const Net ptr **net**

Description: Gets the net this pin reference is attached to.

(2) Signature: Net ptr **net**

Description: Gets the net this pin reference is attached to (non-const version).

This constness variant has been introduced in version 0.26.8

new

Signature: *[static]* new NetSubcircuitPinRef ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

pin

Signature: *[const]* const Pin ptr **pin**

Description: Gets the Pin object of the pin the connection is made to.

pin_id

Signature: *[const]* unsigned long **pin_id**

Description: Gets the ID of the pin the connection is made to.

subcircuit

(1) Signature: *[const]* const SubCircuit ptr **subcircuit**

Description: Gets the subcircuit reference.

This attribute indicates the subcircuit the net attaches to. The subcircuit lives in the same circuit than the net.

(2) Signature: SubCircuit ptr **subcircuit**

Description: Gets the subcircuit reference (non-const version).

This attribute indicates the subcircuit the net attaches to. The subcircuit lives in the same circuit than the net.

This constness variant has been introduced in version 0.26.8

4.126. API reference - Class Net

Notation used in Ruby API documentation

Module: db

Description: A single net.

Class hierarchy: Net » NetlistObject

A net connects multiple pins or terminals together. Pins are either pin or subcircuits of outgoing pins of the circuit the net lives in. Terminals are connections made to specific terminals of devices.

Net objects are created inside a circuit with Circuit#create_net.

To connect a net to an outgoing pin of a circuit, use Circuit#connect_pin, to disconnect a net from an outgoing pin use Circuit#disconnect_pin. To connect a net to a pin of a subcircuit, use SubCircuit#connect_pin, to disconnect a net from a pin of a subcircuit, use SubCircuit#disconnect_pin. To connect a net to a terminal of a device, use Device#connect_terminal, to disconnect a net from a terminal of a device, use Device#disconnect_terminal.

This class has been added in version 0.26.

Public methods

	void	**_assign**	(const Net other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new Net ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	Circuit ptr	**circuit**		Gets the circuit the net lives in.
	void	**clear**		Clears the net.
[const]	unsigned long	**cluster_id**		Gets the cluster ID of the net.
	void	**cluster_id=**	(unsigned long id)	Sets the cluster ID of the net.
[const,iter]	NetPinRef	**each_pin**		Iterates over all outgoing pins the net connects.
[iter]	NetPinRef	**each_pin**		Iterates over all outgoing pins the net connects (non-const version).
[const,iter]	NetSubcircuitPinRef	**each_subcircuit_pin**		Iterates over all subcircuit pins the net connects.

[iter]	NetSubcircuitPinRef	**each_subcircuit_pin**		Iterates over all subcircuit pins the net connects (non-const version).
[const,iter]	NetTerminalRef	**each_terminal**		Iterates over all terminals the net connects.
[iter]	NetTerminalRef	**each_terminal**		Iterates over all terminals the net connects (non-const version).
[const]	string	**expanded_name**		Gets the expanded name of the net.
[const]	bool	**is_floating?**		Returns true, if the net is floating.
[const]	bool	**is_internal?**		Returns true, if the net is an internal net.
[const]	bool	**is_passive?**		Returns true, if the net is passive.
[const]	string	**name**		Gets the name of the net.
	void	**name=**	(string name)	Sets the name of the net.
[const]	unsigned long	**pin_count**		Returns the number of outgoing pins connected by this net.
[const]	string	**qname**		Gets the qualified name.
[const]	unsigned long	**subcircuit_pin_count**		Returns the number of subcircuit pins connected by this net.
[const]	unsigned long	**terminal_count**		Returns the number of terminals connected by this net.
[const]	string	**to_s**		Gets the qualified name.

Detailed description

_assign

Signature: void **_assign** (const Net other)

Description: Assigns another object to self

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_dup

Signature: *[const]* new Net ptr **_dup**

Description: Creates a copy of self

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

circuit

Signature: Circuit ptr **circuit**

Description: Gets the circuit the net lives in.

clear

Signature: void **clear**

Description: Clears the net.

cluster_id

Signature: *[const]* unsigned long **cluster_id**

Description: Gets the cluster ID of the net.

See cluster_id= for details about the cluster ID.

Python specific notes:
The object exposes a readable attribute 'cluster_id'. This is the getter.

cluster_id=

Signature: void **cluster_id=** (unsigned long id)

Description: Sets the cluster ID of the net.

The cluster ID connects the net with a layout cluster. It is set when the net is extracted from a layout.

Python specific notes:
The object exposes a writable attribute 'cluster_id'. This is the setter.

each_pin

(1) Signature: *[const,iter]* NetPinRef **each_pin**

Description: Iterates over all outgoing pins the net connects.

Pin connections are described by NetPinRef objects. Pin connections are connections to outgoing pins of the circuit the net lives in.

(2) Signature: *[iter]* NetPinRef **each_pin**

Description: Iterates over all outgoing pins the net connects (non-const version).

Pin connections are described by NetPinRef objects. Pin connections are connections to outgoing pins of the circuit the net lives in.

This constness variant has been introduced in version 0.26.8

each_subcircuit_pin

(1) Signature: *[const,iter]* NetSubcircuitPinRef **each_subcircuit_pin**

Description: Iterates over all subcircuit pins the net connects.

Subcircuit pin connections are described by NetSubcircuitPinRef objects. These are connections to specific pins of subcircuits.

(2) Signature: *[iter]* NetSubcircuitPinRef **each_subcircuit_pin**

Description: Iterates over all subcircuit pins the net connects (non-const version).

Subcircuit pin connections are described by NetSubcircuitPinRef objects. These are connections to specific pins of subcircuits.

This constness variant has been introduced in version 0.26.8

each_terminal

(1) Signature: *[const,iter]* NetTerminalRef **each_terminal**

Description: Iterates over all terminals the net connects.

Terminals connect devices. Terminal connections are described by NetTerminalRef objects.

(2) Signature: *[iter]* NetTerminalRef **each_terminal**

Description: Iterates over all terminals the net connects (non-const version).

Terminals connect devices. Terminal connections are described by NetTerminalRef objects.

This constness variant has been introduced in version 0.26.8

expanded_name

Signature: *[const]* string **expanded_name**

Description: Gets the expanded name of the net.

The expanded name takes the name of the net. If the name is empty, the cluster ID will be used to build a name.

is_floating?

Signature: *[const]* bool **is_floating?**

Description: Returns true, if the net is floating.

Floating nets are those which don't have any device or subcircuit on it and are not connected through a pin.

is_internal?

Signature: *[const]* bool **is_internal?**

Description: Returns true, if the net is an internal net.

Internal nets are those which connect exactly two terminals and nothing else (pin_count = 0 and terminal_count == 2).

is_passive?

Signature: *[const]* bool **is_passive?**

Description: Returns true, if the net is passive.

Passive nets don't have devices or subcircuits on it. They can be exposed through a pin. is_floating? implies is_passive?.

This method has been introduced in version 0.26.1.

name

Signature: *[const]* string **name**

Description: Gets the name of the net.

See name= for details about the name.

Python specific notes:
The object exposes a readable attribute 'name'. This is the getter.

name=

Signature: void **name=** (string name)

Description: Sets the name of the net.

The name of the net is used for naming the net in schematic files for example. The name of the net has to be unique.

Python specific notes:
The object exposes a writable attribute 'name'. This is the setter.

pin_count

Signature: *[const]* unsigned long **pin_count**

Description: Returns the number of outgoing pins connected by this net.

qname

Signature: *[const]* string **qname**

Description: Gets the qualified name.

The qualified name is like the expanded name, but the circuit's name is preceded (i.e. 'CIRCUIT:NET') if available.

Python specific notes:
This method is also available as 'str(object)'.

subcircuit_pin_count

Signature: *[const]* unsigned long **subcircuit_pin_count**

Description: Returns the number of subcircuit pins connected by this net.

terminal_count

Signature: *[const]* unsigned long **terminal_count**

Description: Returns the number of terminals connected by this net.

to_s

Signature: *[const]* string **to_s**

Description: Gets the qualified name.

The qualified name is like the expanded name, but the circuit's name is preceded (i.e. 'CIRCUIT:NET') if available.

Python specific notes:
This method is also available as 'str(object)'.

4.127. API reference - Class DeviceTerminalDefinition

Notation used in Ruby API documentation

Module: db

Description: A terminal descriptor

This class is used inside the DeviceClass class to describe a terminal of the device.

This class has been added in version 0.26.

Public constructors

new DeviceTerminalDefinition ptr	**new**	(string name, string description =)	Creates a new terminal definition.

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const DeviceTermin other)	Assigns another object to self
[const]	string	**description**		Gets the description of the terminal.
	void	**description=**	(string description)	Sets the description of the terminal.
[const]	new DeviceTerminalDefinition ptr	**dup**		Creates a copy of self
[const]	unsigned long	**id**		Gets the ID of the terminal.
[const]	string	**name**		Gets the name of the terminal.
	void	**name=**	(string name)	Sets the name of the terminal.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead

	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const DeviceTerminalDefinition other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

description

Signature: *[const]* string **description**

Description: Gets the description of the terminal.

Python specific notes:
The object exposes a readable attribute 'description'. This is the getter.

description=

Signature: void **description=** (string description)

Description: Sets the description of the terminal.

Python specific notes:
The object exposes a writable attribute 'description'. This is the setter.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new DeviceTerminalDefinition ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

id

Signature: *[const]* unsigned long **id**

Description: Gets the ID of the terminal.

The ID of the terminal is used in some places to refer to a specific terminal (e.g. in the NetTerminalRef object).

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

	This method returns true, if self is a const reference. In that case, only const methods may be called on self.
name	**Signature**: *[const]* string **name** **Description**: Gets the name of the terminal. **Python specific notes:** The object exposes a readable attribute 'name'. This is the getter.
name=	**Signature**: void **name=** (string name) **Description**: Sets the name of the terminal. **Python specific notes:** The object exposes a writable attribute 'name'. This is the setter.
new	**Signature**: *[static]* new DeviceTerminalDefinition ptr **new** (string name, string description =) **Description**: Creates a new terminal definition. **Python specific notes:** This method is the default initializer of the object.

4.128. API reference - Class DeviceParameterDefinition

Notation used in Ruby API documentation

Module: db

Description: A parameter descriptor

This class is used inside the DeviceClass class to describe a parameter of the device.

This class has been added in version 0.26.

Public constructors

new DeviceParameterDefinition ptr	**new**	(string name, string description = , double default_value = 0, bool is_primary = true, double si_scaling = 1, double geo_scaling_exponent = 0)	Creates a new parameter definition.

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const DeviceParamet other)	Assigns another object to self
[const]	double	**default_value**		Gets the default value of the parameter.
	void	**default_value=**	(double default_value)	Sets the default value of the parameter.
[const]	string	**description**		Gets the description of the parameter.
	void	**description=**	(string description)	Sets the description of the parameter.
[const]	new DeviceParameterDefinition ptr	**dup**		Creates a copy of self
[const]	double	**geo_scaling_exponent**		Gets the geometry scaling exponent.

	void	geo_scaling_exponent=	(double expo)	Sets the geometry scaling exponent.
[const]	unsigned long	id		Gets the ID of the parameter.
	void	is_primary=	(bool primary)	Sets a value indicating whether the parameter is a primary parameter
[const]	bool	is_primary?		Gets a value indicating whether the parameter is a primary parameter
[const]	string	name		Gets the name of the parameter.
	void	name=	(string name)	Sets the name of the parameter.
[const]	double	si_scaling		Gets the scaling factor to SI units.
	void	si_scaling=	(double flag)	Sets the scaling factor to SI units.

Deprecated methods (protected, public, static, non-static and constructors)

	void	create	Use of this method is deprecated. Use _create instead
	void	destroy	Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	is_const_object?	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const DeviceParameterDefinition other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

default_value

Signature: *[const]* double **default_value**

Description: Gets the default value of the parameter.

Python specific notes:
The object exposes a readable attribute 'default_value'. This is the getter.

default_value=

Signature: void **default_value=** (double default_value)

Description: Sets the default value of the parameter.

The default value is used to initialize parameters of Device objects.

Python specific notes:
The object exposes a writable attribute 'default_value'. This is the setter.

description

Signature: *[const]* string **description**

Description: Gets the description of the parameter.

Python specific notes:

The object exposes a readable attribute 'description'. This is the getter.

description=

Signature: void **description=** (string description)

Description: Sets the description of the parameter.

Python specific notes:
The object exposes a writable attribute 'description'. This is the setter.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new DeviceParameterDefinition ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

geo_scaling_exponent

Signature: *[const]* double **geo_scaling_exponent**

Description: Gets the geometry scaling exponent.

This value is used when applying '.options scale' in the SPICE reader for example. It is zero for 'no scaling', 1.0 for linear scaling and 2.0 for quadratic scaling.

This attribute has been added in version 0.28.6.

Python specific notes:
The object exposes a readable attribute 'geo_scaling_exponent'. This is the getter.

geo_scaling_exponent=

Signature: void **geo_scaling_exponent=** (double expo)

Description: Sets the geometry scaling exponent.

See geo_scaling_exponent for details.

This attribute has been added in version 0.28.6.

Python specific notes:
The object exposes a writable attribute 'geo_scaling_exponent'. This is the setter.

id

Signature: *[const]* unsigned long **id**

Description: Gets the ID of the parameter.

The ID of the parameter is used in some places to refer to a specific parameter (e.g. in the NetParameterRef object).

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

is_primary=

Signature: void **is_primary=** (bool primary)

Description: Sets a value indicating whether the parameter is a primary parameter

If this flag is set to true (the default), the parameter is considered a primary parameter. Only primary parameters are compared by default.

Python specific notes:
The object exposes a writable attribute 'is_primary'. This is the setter.

is_primary?

Signature: *[const]* bool **is_primary?**

Description: Gets a value indicating whether the parameter is a primary parameter

See is_primary= for details about this predicate.

Python specific notes:
The object exposes a readable attribute 'is_primary'. This is the getter.

name

Signature: *[const]* string **name**

Description: Gets the name of the parameter.

Python specific notes:
The object exposes a readable attribute 'name'. This is the getter.

name=

Signature: void **name=** (string name)

Description: Sets the name of the parameter.

Python specific notes:
The object exposes a writable attribute 'name'. This is the setter.

new

Signature: *[static]* new DeviceParameterDefinition ptr **new** (string name, string description = , double default_value = 0, bool is_primary = true, double si_scaling = 1, double geo_scaling_exponent = 0)

Description: Creates a new parameter definition.

name:	The name of the parameter
description:	The human-readable description
default_value:	The initial value
is_primary:	True, if the parameter is a primary parameter (see is_primary=)
si_scaling:	The scaling factor to SI units
geo_scaling_exponent:	Indicates how the parameter scales with geometrical scaling (0: no scaling, 1.0: linear, 2.0: quadratic)

Python specific notes:
This method is the default initializer of the object.

si_scaling

Signature: *[const]* double **si_scaling**

Description: Gets the scaling factor to SI units.

For parameters in micrometers - for example W and L of MOS devices - this factor can be set to 1e-6 to reflect the unit.

Python specific notes:
The object exposes a readable attribute 'si_scaling'. This is the getter.

si_scaling=

Signature: void **si_scaling=** (double flag)

Description: Sets the scaling factor to SI units.

This setter has been added in version 0.28.6.

Python specific notes:
The object exposes a writable attribute 'si_scaling'. This is the setter.

4.129. API reference - Class EqualDeviceParameters

Notation used in Ruby API documentation

Module: db

Description: A device parameter equality comparer.

Attach this object to a device class with DeviceClass#equal_parameters= to make the device class use this comparer:

```
# 20nm tolerance for length:
equal_device_parameters = RBA::EqualDeviceParameters::new(RBA::DeviceClassMOS4Transistor::PARAM_L, 0.02, 0.0)
# one percent tolerance for width:
equal_device_parameters += RBA::EqualDeviceParameters::new(RBA::DeviceClassMOS4Transistor::PARAM_W, 0.0,
 0.01)
# applies the compare delegate:
netlist.device_class_by_name("NMOS").equal_parameters = equal_device_parameters
```

You can use this class to specify fuzzy equality criteria for the comparison of device parameters in netlist verification or to confine the equality of devices to certain parameters only.

This class has been added in version 0.26.

Public constructors

new EqualDeviceParameters ptr	**new**	(unsigned long param_id, double absolute = 0, double relative = 0)	Creates a device parameter comparer for a single parameter.

Public methods

[const]	EqualDeviceParameters	**+**	(const EqualDevicePara other)	Combines two parameters for comparison.
[const]	EqualDeviceParameters	**+=**	(const EqualDeviceParameters other)	Combines two parameters for comparison (in-place).
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const EqualDevicePara other)	Assigns another object to self

[const]	new EqualDeviceParameters ptr	**dup**	Creates a copy of self

Public static methods and constants

	new EqualDeviceParameters ptr	**ignore**	(unsigned long param_id)	Creates a device parameter comparer which ignores the parameter.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

+

Signature: *[const]* EqualDeviceParameters **+** (const EqualDeviceParameters other)

Description: Combines two parameters for comparison.

The '+' operator will join the parameter comparers and produce one that checks the combined parameters.

+=

Signature: *[const]* EqualDeviceParameters **+=** (const EqualDeviceParameters other)

Description: Combines two parameters for comparison (in-place).

The '+=' operator will join the parameter comparers and produce one that checks the combined parameters.

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const EqualDeviceParameters other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new EqualDeviceParameters ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

ignore

Signature: *[static]* new EqualDeviceParameters ptr **ignore** (unsigned long param_id)

Description: Creates a device parameter comparer which ignores the parameter.

This specification can be used to make a parameter ignored. Starting with version 0.27.4, all primary parameters are compared. Before 0.27.4, giving a tolerance meant only those parameters are compared. To exclude a primary parameter from the compare, use the 'ignore' specification for that parameter.

This constructor has been introduced in version 0.27.4.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new EqualDeviceParameters ptr **new** (unsigned long param_id, double absolute = 0, double relative = 0)

Description: Creates a device parameter comparer for a single parameter.

'absolute' is the absolute deviation allowed for the parameter values. 'relative' is the relative deviation allowed for the parameter values (a value between 0 and 1).

A value of 0 for both absolute and relative deviation means the parameters have to match exactly.

If 'absolute' and 'relative' are both given, their deviations will add to the allowed difference between two parameter values. The relative deviation will be applied to the mean value of both parameter values. For example, when comparing parameter values of 40 and 60, a relative deviation of 0.35 means an absolute deviation of 17.5 (= 0.35 * average of 40 and 60) which does not make both values match.

Python specific notes:
This method is the default initializer of the object.

4.130. API reference - Class GenericDeviceParameterCompare

Notation used in Ruby API documentation

Module: db

Description: A class implementing the comparison of device parameters.

Class hierarchy: GenericDeviceParameterCompare » EqualDeviceParameters

Reimplement this class to provide a custom device parameter compare scheme. Attach this object to a device class with DeviceClass#equal_parameters= to make the device class use this comparer.

This class is intended for special cases. In most scenarios it is easier to use EqualDeviceParameters instead of implementing a custom comparer class.

This class has been added in version 0.26. The 'equal' method has been dropped in 0.27.1 as it can be expressed as !less(a,b) && ! less(b,a).

Public methods

	void	**_assign**	(const GenericDevice other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new GenericDeviceParame ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[virtual,const	bool	**less**	(const Device device_a, const Device device_b)	Compares the parameters of two devices for a begin less than b. Returns true, if the parameters of device a are considered less than those of device b.The 'less' implementation needs to ensure strict weak ordering. Specifically, less(a,b) == false and less(b,a) implies that a is equal to b and less(a,b) == true implies that less(b,a) is false and vice versa. If not, an internal error will be encountered on netlist compare.

Detailed description

_assign

Signature: void **_assign** (const GenericDeviceParameterCompare other)

Description: Assigns another object to self

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_dup

Signature: *[const]* new GenericDeviceParameterCompare ptr **_dup**

Description: Creates a copy of self

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

less

Signature: *[virtual,const]* bool **less** (const Device device_a, const Device device_b)

Description: Compares the parameters of two devices for a begin less than b. Returns true, if the parameters of device a are considered less than those of device b.The 'less' implementation needs to ensure strict weak ordering. Specifically, less(a,b) == false and less(b,a) implies that a is equal to

b and less(a,b) == true implies that less(b,a) is false and vice versa. If not, an internal error will be encountered on netlist compare.

4.131. API reference - Class GenericDeviceCombiner

Notation used in Ruby API documentation

Module: db

Description: A class implementing the combination of two devices (parallel or serial mode).

Reimplement this class to provide a custom device combiner. Device combination requires 'supports_paralell_combination' or 'supports_serial_combination' to be set to true for the device class. In the netlist device combination step, the algorithm will try to identify devices which can be combined into single devices and use the combiner object to implement the actual joining of such devices.

Attach this object to a device class with DeviceClass#combiner= to make the device class use this combiner.

This class has been added in version 0.27.3.

Public constructors

new GenericDeviceCombiner ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const GenericDevice(other)	Assigns another object to self
[virtual,const]	bool	**combine_devices**	(Device ptr device_a, Device ptr device_b)	Combines two devices if possible.
[const]	new GenericDeviceCombine ptr	**dup**		Creates a copy of self

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead

[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const GenericDeviceCombiner other)

Description: Assigns another object to self

combine_devices

Signature: *[virtual,const]* bool **combine_devices** (Device ptr device_a, Device ptr device_b)

Description: Combines two devices if possible.

This method needs to test, whether the two devices can be combined. Both devices are guaranteed to share the same device class. If they cannot be combined, this method shall do nothing and return false. If they can be combined, this method shall reconnect the nets of the first device and entirely disconnect the nets of the second device. The second device will be deleted afterwards.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new GenericDeviceCombiner ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new GenericDeviceCombiner ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

4.132. API reference - Class DeviceClass

Notation used in Ruby API documentation

Module: db

Description: A class describing a specific type of device.

Device class objects live in the context of a Netlist object. After a device class is created, it must be added to the netlist using Netlist#add. The netlist will own the device class object. When the netlist is destroyed, the device class object will become invalid.

The DeviceClass class is the base class for other device classes.

This class has been added in version 0.26. In version 0.27.3, the 'GenericDeviceClass' has been integrated with DeviceClass and the device class was made writeable in most respects. This enables manipulating built-in device classes.

Public constructors

new DeviceClass ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**add_parameter**	(DeviceParameterD ptr parameter_def)	Adds the given parameter definition to the device class
	void	**add_terminal**	(DeviceTerminalDefinition ptr terminal_def)	Adds the given terminal definition to the device class
	void	**assign**	(const DeviceClass other)	Assigns another object to self
	void	**clear_equivalent_terminal_ids**		Clears all equivalent terminal ids
	void	**clear_parameters**		Clears the list of parameters
	void	**clear_terminals**		Clears the list of terminals
	GenericDeviceCombine ptr	**combiner**		Gets a device combiner or nil if none is registered.

	void	**combiner=**	(GenericDeviceCombiner ptr combiner)	Specifies a device combiner (parallel or serial device combination).
[const]	string	**description**		Gets the description text of the device class.
	void	**description=**	(string description)	Sets the description of the device class.
[const]	new DeviceClass ptr	**dup**		Creates a copy of self
	void	**enable_parameter**	(unsigned long parameter_id, bool enable)	Enables or disables a parameter.
	void	**enable_parameter**	(string parameter_name, bool enable)	Enables or disables a parameter.
	EqualDeviceParameters ptr	**equal_parameters**		Gets the device parameter comparer for netlist verification or nil if no comparer is registered.
	void	**equal_parameters=**	(EqualDeviceParam ptr comparer)	Specifies a device parameter comparer for netlist verification.
	void	**equivalent_terminal_id**	(unsigned long original_id, unsigned long equivalent_id)	Specifies a terminal to be equivalent to another.
[const]	bool	**has_parameter?**	(string name)	Returns true, if the device class has a parameter with the given name.
[const]	bool	**has_terminal?**	(string name)	Returns true, if the device class has a terminal with the given name.
[const]	unsigned long	**id**		Gets the unique ID of the device class
[const]	string	**name**		Gets the name of the device class.
	void	**name=**	(string name)	Sets the name of the device class.
	Netlist ptr	**netlist**		Gets the netlist the device class lives in.
[const]	const DeviceParameterDefini ptr	**parameter_definition**	(unsigned long parameter_id)	Gets the parameter definition object for a given ID.
[const]	const DeviceParameterDefinition ptr	**parameter_definition**	(string parameter_name)	Gets the parameter definition object for a given ID.
[const]	DeviceParameterDefini	**parameter_definitions**		Gets the list of parameter definitions of the device.
[const]	unsigned long	**parameter_id**	(string name)	Returns the parameter ID of the parameter with the given name.

	void	strict=	(bool s)	Sets a value indicating whether this class performs strict terminal mapping
[const]	bool	strict?		Gets a value indicating whether this class performs strict terminal mapping
	void	supports_parallel_comb	(bool f)	Specifies whether the device supports parallel device combination.
	void	supports_serial_combinations=	(bool f)	Specifies whether the device supports serial device combination.
[const]	const DeviceTerminalDefiniti ptr	terminal_definition	(unsigned long terminal_id)	Gets the terminal definition object for a given ID.
[const]	DeviceTerminalDefinition[]	terminal_definitions		Gets the list of terminal definitions of the device.
[const]	unsigned long	terminal_id	(string name)	Returns the terminal ID of the terminal with the given name.

Deprecated methods (protected, public, static, non-static and constructors)

	void	create	Use of this method is deprecated. Use _create instead
	void	destroy	Use of this method is deprecated. Use _destroy instead
[const]	bool	destroyed?	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	is_const_object?	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

add_parameter

Signature: void **add_parameter** (DeviceParameterDefinition ptr parameter_def)

Description: Adds the given parameter definition to the device class

This method will define a new parameter. The new parameter is added at the end of existing parameters. The parameter definition object passed as the argument is modified to contain the new ID of the parameter. The parameter is copied into the device class. Modifying the parameter object later does not have the effect of changing the parameter definition.

This method has been moved from 'GenericDeviceClass' to 'DeviceClass' in version 0.27.3.

add_terminal

Signature: void **add_terminal** (DeviceTerminalDefinition ptr terminal_def)

Description: Adds the given terminal definition to the device class

This method will define a new terminal. The new terminal is added at the end of existing terminals. The terminal definition object passed as the argument is modified to contain the new ID of the terminal.

The terminal is copied into the device class. Modifying the terminal object later does not have the effect of changing the terminal definition.

This method has been moved from 'GenericDeviceClass' to 'DeviceClass' in version 0.27.3.

assign

Signature: void **assign** (const DeviceClass other)

Description: Assigns another object to self

clear_equivalent_terminal_ids

Signature: void **clear_equivalent_terminal_ids**

Description: Clears all equivalent terminal ids

This method has been added in version 0.27.3.

clear_parameters

Signature: void **clear_parameters**

Description: Clears the list of parameters

This method has been added in version 0.27.3.

clear_terminals

Signature: void **clear_terminals**

Description: Clears the list of terminals

This method has been moved from 'GenericDeviceClass' to 'DeviceClass' in version 0.27.3.

combiner

Signature: GenericDeviceCombiner ptr **combiner**

Description: Gets a device combiner or nil if none is registered.

This method has been added in version 0.27.3.

Python specific notes:
The object exposes a readable attribute 'combiner'. This is the getter.

combiner=

Signature: void **combiner=** (GenericDeviceCombiner ptr combiner)

Description: Specifies a device combiner (parallel or serial device combination).

You can assign nil for the combiner to remove it.

In special cases, you can even implement a custom combiner by deriving your own comparer from the GenericDeviceCombiner class.

This method has been added in version 0.27.3.

Python specific notes:
The object exposes a writable attribute 'combiner'. This is the setter.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

description

Signature: *[const]* string **description**

Description: Gets the description text of the device class.

Python specific notes:
The object exposes a readable attribute 'description'. This is the getter.

description=

Signature: void **description=** (string description)

Description: Sets the description of the device class.

Python specific notes:
The object exposes a writable attribute 'description'. This is the setter.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new DeviceClass ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

enable_parameter

(1) Signature: void **enable_parameter** (unsigned long parameter_id, bool enable)

Description: Enables or disables a parameter.

Some parameters are 'secondary' parameters which are extracted but not handled in device compare and are not shown in the netlist browser. For example, the 'W' parameter of the resistor is such a secondary parameter. This method allows turning a parameter in a primary one ('enable') or into a secondary one ('disable').

This method has been introduced in version 0.27.3.

(2) Signature: void **enable_parameter** (string parameter_name, bool enable)

Description: Enables or disables a parameter.

Some parameters are 'secondary' parameters which are extracted but not handled in device compare and are not shown in the netlist browser. For example, the 'W' parameter of the resistor is such a secondary parameter. This method allows turning a parameter in a primary one ('enable') or into a secondary one ('disable').

This version accepts a parameter name.

This method has been introduced in version 0.27.3.

equal_parameters

Signature: EqualDeviceParameters ptr **equal_parameters**

Description: Gets the device parameter comparer for netlist verification or nil if no comparer is registered.

See equal_parameters= for the setter.

This method has been moved from 'GenericDeviceClass' to 'DeviceClass' in version 0.27.3.

Python specific notes:
The object exposes a readable attribute 'equal_parameters'. This is the getter.

equal_parameters=

Signature: void **equal_parameters=** (EqualDeviceParameters ptr comparer)

Description: Specifies a device parameter comparer for netlist verification.

By default, all devices are compared with all parameters. If you want to select only certain parameters for comparison or use a fuzzy compare criterion, use an EqualDeviceParameters object and assign it to the device class of one netlist. You can also chain multiple EqualDeviceParameters objects with the '+' operator for specifying multiple parameters in the equality check.

You can assign nil for the parameter comparer to remove it.

	In special cases, you can even implement a custom compare scheme by deriving your own comparer from the GenericDeviceParameterCompare class. This method has been moved from 'GenericDeviceClass' to 'DeviceClass' in version 0.27.3. **Python specific notes:** The object exposes a writable attribute 'equal_parameters'. This is the setter.
equivalent_terminal_id	**Signature**: void **equivalent_terminal_id** (unsigned long original_id, unsigned long equivalent_id) **Description**: Specifies a terminal to be equivalent to another. Use this method to specify two terminals to be exchangeable. For example to make S and D of a MOS transistor equivalent, call this method with S and D terminal IDs. In netlist matching, S will be translated to D and thus made equivalent to D. Note that terminal equivalence is not effective if the device class operates in strict mode (see DeviceClass#strict=). This method has been moved from 'GenericDeviceClass' to 'DeviceClass' in version 0.27.3.
has_parameter?	**Signature**: *[const]* bool **has_parameter?** (string name) **Description**: Returns true, if the device class has a parameter with the given name.
has_terminal?	**Signature**: *[const]* bool **has_terminal?** (string name) **Description**: Returns true, if the device class has a terminal with the given name.
id	**Signature**: *[const]* unsigned long **id** **Description**: Gets the unique ID of the device class The ID is a unique integer that identifies the device class. Use the ID to check for object identity - i.e. to determine whether two devices share the same device class.
is_const_object?	**Signature**: *[const]* bool **is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.
name	**Signature**: *[const]* string **name** **Description**: Gets the name of the device class. **Python specific notes:** The object exposes a readable attribute 'name'. This is the getter.
name=	**Signature**: void **name=** (string name) **Description**: Sets the name of the device class. **Python specific notes:** The object exposes a writable attribute 'name'. This is the setter.
netlist	**Signature**: Netlist ptr **netlist** **Description**: Gets the netlist the device class lives in.

new

Signature: *[static]* new DeviceClass ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

parameter_definition

(1) Signature: *[const]* const DeviceParameterDefinition ptr **parameter_definition** (unsigned long parameter_id)

Description: Gets the parameter definition object for a given ID.

Parameter definition IDs are used in some places to reference a specific parameter of a device. This method obtains the corresponding definition object.

(2) Signature: *[const]* const DeviceParameterDefinition ptr **parameter_definition** (string parameter_name)

Description: Gets the parameter definition object for a given ID.

Parameter definition IDs are used in some places to reference a specific parameter of a device. This method obtains the corresponding definition object. This version accepts a parameter name.

This method has been introduced in version 0.27.3.

parameter_definitions

Signature: *[const]* DeviceParameterDefinition[] **parameter_definitions**

Description: Gets the list of parameter definitions of the device.

See the DeviceParameterDefinition class description for details.

parameter_id

Signature: *[const]* unsigned long **parameter_id** (string name)

Description: Returns the parameter ID of the parameter with the given name.

An exception is thrown if there is no parameter with the given name. Use has_parameter to check whether the name is a valid parameter name.

strict=

Signature: void **strict=** (bool s)

Description: Sets a value indicating whether this class performs strict terminal mapping

Classes with this flag set never allow terminal swapping, even if the device symmetry supports that. If two classes are involved in a netlist compare, terminal swapping will be disabled if one of the classes is in strict mode.

By default, device classes are not strict and terminal swapping is allowed as far as the device symmetry supports that.

Python specific notes:
The object exposes a writable attribute 'strict'. This is the setter.

strict?

Signature: *[const]* bool **strict?**

Description: Gets a value indicating whether this class performs strict terminal mapping

See strict= for details about this attribute.

Python specific notes:
The object exposes a readable attribute 'strict'. This is the getter.

supports_parallel_combination=

Signature: void **supports_parallel_combination=** (bool f)

Description: Specifies whether the device supports parallel device combination.

Parallel device combination means that all terminals of two combination candidates are connected to the same nets. If the device does not support this combination mode, this predicate can be set

to false. This will make the device extractor skip the combination test in parallel mode and improve performance somewhat.

This method has been moved from 'GenericDeviceClass' to 'DeviceClass' in version 0.27.3.

Python specific notes:
The object exposes a writable attribute 'supports_parallel_combination'. This is the setter.

supports_serial_combination

Signature: void **supports_serial_combination=** (bool f)

Description: Specifies whether the device supports serial device combination.

Serial device combination means that the devices are connected by internal nodes. If the device does not support this combination mode, this predicate can be set to false. This will make the device extractor skip the combination test in serial mode and improve performance somewhat.

This method has been moved from 'GenericDeviceClass' to 'DeviceClass' in version 0.27.3.

Python specific notes:
The object exposes a writable attribute 'supports_serial_combination'. This is the setter.

terminal_definition

Signature: *[const]* const DeviceTerminalDefinition ptr **terminal_definition** (unsigned long terminal_id)

Description: Gets the terminal definition object for a given ID.

Terminal definition IDs are used in some places to reference a specific terminal of a device. This method obtains the corresponding definition object.

terminal_definitions

Signature: *[const]* DeviceTerminalDefinition[] **terminal_definitions**

Description: Gets the list of terminal definitions of the device.

See the DeviceTerminalDefinition class description for details.

terminal_id

Signature: *[const]* unsigned long **terminal_id** (string name)

Description: Returns the terminal ID of the terminal with the given name.

An exception is thrown if there is no terminal with the given name. Use has_terminal to check whether the name is a valid terminal name.

4.133. API reference - Class Circuit

Notation used in Ruby API documentation

Module: db

Description: Circuits are the basic building blocks of the netlist

Class hierarchy: Circuit » NetlistObject

A circuit has pins by which it can connect to the outside. Pins are created using create_pin and are represented by the Pin class.

Furthermore, a circuit manages the components of the netlist. Components are devices (class Device) and subcircuits (class SubCircuit). Devices are basic devices such as resistors or transistors. Subcircuits are other circuits to which nets from this circuit connect. Devices are created using the create_device method. Subcircuits are created using the create_subcircuit method.

Devices are connected through 'terminals', subcircuits are connected through their pins. Terminals and pins are described by integer ID's in the context of most methods.

Finally, the circuit consists of the nets. Nets connect terminals of devices and pins of subcircuits or the circuit itself. Nets are created using create_net and are represented by objects of the Net class. See there for more about nets.

The Circuit object is only valid if the netlist object is alive. Circuits must be added to a netlist using Netlist#add to become part of the netlist.

The Circuit class has been introduced in version 0.26.

Public methods

	void	**_assign**	(const Circuit other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new Circuit ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**blank**		Blanks out the circuit
[const]	DPolygon	**boundary**		Gets the boundary of the circuit
	void	**boundary=**	(const DPolygon boundary)	Sets the boundary of the circuit
[const]	unsigned int	**cell_index**		Gets the cell index of the circuit
	void	**cell_index=**	(unsigned int cell_index)	Sets the cell index
	void	**clear**		Clears the circuit

	void	**combine_devices**		Combines devices where possible
	void	**connect_pin**	(unsigned long pin_id, Net ptr net)	Connects the given pin with the given net.
	void	**connect_pin**	(const Pin ptr pin, Net ptr net)	Connects the given pin with the given net.
	Device ptr	**create_device**	(DeviceClass ptr device_class, string name =)	Creates a new bound Device object inside the circuit
	Net ptr	**create_net**	(string name =)	Creates a new Net object inside the circuit
	Pin ptr	**create_pin**	(string name)	Creates a new Pin object inside the circuit
	SubCircuit ptr	**create_subcircuit**	(Circuit ptr circuit, string name =)	Creates a new bound SubCircuit object inside the circuit
	Device ptr	**device_by_id**	(unsigned long id)	Gets the device object for a given ID.
[const]	const Device ptr	**device_by_id**	(unsigned long id)	Gets the device object for a given ID (const version).
	Device ptr	**device_by_name**	(string name)	Gets the device object for a given name.
[const]	const Device ptr	**device_by_name**	(string name)	Gets the device object for a given name (const version).
	void	**disconnect_pin**	(unsigned long pin_id)	Disconnects the given pin from any net.
	void	**disconnect_pin**	(const Pin ptr pin)	Disconnects the given pin from any net.
[const]	bool	**dont_purge**		Gets a value indicating whether the circuit can be purged on Netlist#purge.
	void	**dont_purge=**	(bool f)	Sets a value indicating whether the circuit can be purged on Netlist#purge.
[iter]	Circuit	**each_child**		Iterates over the child circuits of this circuit
[const,iter]	Circuit	**each_child**		Iterates over the child circuits of this circuit (const version)
[iter]	Device	**each_device**		Iterates over the devices of the circuit
[const,iter]	Device	**each_device**		Iterates over the devices of the circuit (const version)
[iter]	Net	**each_net**		Iterates over the nets of the circuit
[const,iter]	Net	**each_net**		Iterates over the nets of the circuit (const version)
[iter]	Circuit	**each_parent**		Iterates over the parent circuits of this circuit

[const,iter]	Circuit	**each_parent**		Iterates over the parent circuits of this circuit (const version)
[iter]	Pin	**each_pin**		Iterates over the pins of the circuit
[const,iter]	Pin	**each_pin**		Iterates over the pins of the circuit (const version)
[iter]	SubCircuit	**each_ref**		Iterates over the subcircuit objects referencing this circuit
[const,iter]	SubCircuit	**each_ref**		Iterates over the subcircuit objects referencing this circuit (const version)
[iter]	SubCircuit	**each_subcircuit**		Iterates over the subcircuits of the circuit
[const,iter]	SubCircuit	**each_subcircuit**		Iterates over the subcircuits of the circuit (const version)
	void	**flatten_subcircuit**	(SubCircuit ptr subcircuit)	Flattens a subcircuit
[const]	bool	**has_refs?**		Returns a value indicating whether the circuit has references
	void	**join_nets**	(Net ptr net, Net ptr with)	Joins (connects) two nets into one
[const]	string	**name**		Gets the name of the circuit
	void	**name=**	(string name)	Sets the name of the circuit
	Net ptr	**net_by_cluster_id**	(unsigned long cluster_id)	Gets the net object corresponding to a specific cluster ID
	Net ptr	**net_by_name**	(string name)	Gets the net object for a given name.
[const]	const Net ptr	**net_by_name**	(string name)	Gets the net object for a given name (const version).
	Net ptr	**net_for_pin**	(unsigned long pin_id)	Gets the net object attached to a specific pin.
[const]	const Net ptr	**net_for_pin**	(unsigned long pin_id)	Gets the net object attached to a specific pin (const version).
	Net ptr	**net_for_pin**	(const Pin ptr pin)	Gets the net object attached to a specific pin.
[const]	const Net ptr	**net_for_pin**	(const Pin ptr pin)	Gets the net object attached to a specific pin (const version).
	Netlist ptr	**netlist**		Gets the netlist object the circuit lives in
[const]	const Netlist ptr	**netlist**		Gets the netlist object the circuit lives in (const version)
	Net ptr[]	**nets_by_name**	(string name_pattern)	Gets the net objects for a given name filter.

[const]	const Net ptr[]	**nets_by_name**	(string name_pattern)	Gets the net objects for a given name filter (const version).
	Pin ptr	**pin_by_id**	(unsigned long id)	Gets the Pin object corresponding to a specific ID
[const]	const Pin ptr	**pin_by_id**	(unsigned long id)	Gets the Pin object corresponding to a specific ID (const version)
	Pin ptr	**pin_by_name**	(string name)	Gets the Pin object corresponding to a specific name
[const]	const Pin ptr	**pin_by_name**	(string name)	Gets the Pin object corresponding to a specific name (const version)
[const]	unsigned long	**pin_count**		Gets the number of pins in the circuit
	void	**purge_nets**		Purges floating nets.
	void	**purge_nets_keep_pins**		Purges floating nets but keep pins.
	void	**remove_device**	(Device ptr device)	Removes the given device from the circuit
	void	**remove_net**	(Net ptr net)	Removes the given net from the circuit
	void	**remove_pin**	(unsigned long id)	Removes the pin with the given ID from the circuit
	void	**remove_subcircuit**	(SubCircuit ptr subcircuit)	Removes the given subcircuit from the circuit
	void	**rename_pin**	(unsigned long id, string new_name)	Renames the pin with the given ID to 'new_name'
	SubCircuit ptr	**subcircuit_by_id**	(unsigned long id)	Gets the subcircuit object for a given ID.
[const]	const SubCircuit ptr	**subcircuit_by_id**	(unsigned long id)	Gets the subcircuit object for a given ID (const version).
	SubCircuit ptr	**subcircuit_by_name**	(string name)	Gets the subcircuit object for a given name.
[const]	const SubCircuit ptr	**subcircuit_by_name**	(string name)	Gets the subcircuit object for a given name (const version).

Detailed description

_assign

Signature: void **_assign** (const Circuit other)

Description: Assigns another object to self

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_dup

Signature: *[const]* new Circuit ptr **_dup**

Description: Creates a copy of self

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

blank

Signature: void **blank**

Description: Blanks out the circuit

This method will remove all the innards of the circuit and just leave the pins. The pins won't be connected to inside nets anymore, but the circuit can still be called by subcircuit references. This method will eventually create a 'circuit abstract' (or black box). It will set the dont_purge flag to mark this circuit as 'intentionally empty'.

boundary

Signature: *[const]* DPolygon **boundary**

Description: Gets the boundary of the circuit

Python specific notes:

The object exposes a readable attribute 'boundary'. This is the getter.

boundary=

Signature: void **boundary=** (const DPolygon boundary)

Description: Sets the boundary of the circuit

Python specific notes:
The object exposes a writable attribute 'boundary'. This is the setter.

cell_index

Signature: *[const]* unsigned int **cell_index**

Description: Gets the cell index of the circuit

See cell_index= for details.

Python specific notes:
The object exposes a readable attribute 'cell_index'. This is the getter.

cell_index=

Signature: void **cell_index=** (unsigned int cell_index)

Description: Sets the cell index

The cell index relates a circuit with a cell from a layout. It's intended to hold a cell index number if the netlist was extracted from a layout.

Python specific notes:
The object exposes a writable attribute 'cell_index'. This is the setter.

clear

Signature: void **clear**

Description: Clears the circuit

This method removes all objects and clears the other attributes.

combine_devices

Signature: void **combine_devices**

Description: Combines devices where possible

This method will combine devices that can be combined according to their device classes 'combine_devices' method. For example, serial or parallel resistors can be combined into a single resistor.

connect_pin

(1) Signature: void **connect_pin** (unsigned long pin_id, Net ptr net)

Description: Connects the given pin with the given net.

The net must be one inside the circuit. Any previous connected is resolved before this connection is made. A pin can only be connected to one net at a time.

(2) Signature: void **connect_pin** (const Pin ptr pin, Net ptr net)

Description: Connects the given pin with the given net.

The net and the pin must be objects from inside the circuit. Any previous connected is resolved before this connection is made. A pin can only be connected to one net at a time.

create_device

Signature: Device ptr **create_device** (DeviceClass ptr device_class, string name =)

Description: Creates a new bound Device object inside the circuit

This object describes a device of the circuit. The device is already attached to the device class. The name is optional and is used to identify the device in a netlist file.

For more details see the Device class.

create_net

Signature: Net ptr **create_net** (string name =)

Description: Creates a new Net object inside the circuit

This object will describe a net of the circuit. The nets are basically connections between the different components of the circuit (subcircuits, devices and pins).

A net needs to be filled with references to connect to specific objects. See the Net class for more details.

create_pin

Signature: Pin ptr **create_pin** (string name)

Description: Creates a new Pin object inside the circuit

This object will describe a pin of the circuit. A circuit connects to the outside through such a pin. The pin is added after all existing pins. For more details see the Pin class.

Starting with version 0.26.8, this method returns a reference to a Pin object rather than a copy.

create_subcircuit

Signature: SubCircuit ptr **create_subcircuit** (Circuit ptr circuit, string name =)

Description: Creates a new bound SubCircuit object inside the circuit

This object describes an instance of another circuit inside the circuit. The subcircuit is already attached to the other circuit. The name is optional and is used to identify the subcircuit in a netlist file.

For more details see the SubCircuit class.

device_by_id

(1) Signature: Device ptr **device_by_id** (unsigned long id)

Description: Gets the device object for a given ID.

If the ID is not a valid device ID, nil is returned.

(2) Signature: *[const]* const Device ptr **device_by_id** (unsigned long id)

Description: Gets the device object for a given ID (const version).

If the ID is not a valid device ID, nil is returned.

This constness variant has been introduced in version 0.26.8

device_by_name

(1) Signature: Device ptr **device_by_name** (string name)

Description: Gets the device object for a given name.

If the ID is not a valid device name, nil is returned.

(2) Signature: *[const]* const Device ptr **device_by_name** (string name)

Description: Gets the device object for a given name (const version).

If the ID is not a valid device name, nil is returned.

This constness variant has been introduced in version 0.26.8

disconnect_pin

(1) Signature: void **disconnect_pin** (unsigned long pin_id)

Description: Disconnects the given pin from any net.

(2) Signature: void **disconnect_pin** (const Pin ptr pin)

Description: Disconnects the given pin from any net.

dont_purge

Signature: *[const]* bool **dont_purge**

Description: Gets a value indicating whether the circuit can be purged on Netlist#purge.

Python specific notes:
The object exposes a readable attribute 'dont_purge'. This is the getter.

dont_purge=

Signature: void **dont_purge=** (bool f)

Description: Sets a value indicating whether the circuit can be purged on Netlist#purge.

If this attribute is set to true, Netlist#purge will never delete this circuit. This flag therefore marks this circuit as 'precious'.

Python specific notes:
The object exposes a writable attribute 'dont_purge'. This is the setter.

each_child

(1) Signature: *[iter]* Circuit **each_child**

Description: Iterates over the child circuits of this circuit

Child circuits are the ones that are referenced from this circuit via subcircuits.

(2) Signature: *[const,iter]* Circuit **each_child**

Description: Iterates over the child circuits of this circuit (const version)

Child circuits are the ones that are referenced from this circuit via subcircuits.

This constness variant has been introduced in version 0.26.8

each_device

(1) Signature: *[iter]* Device **each_device**

Description: Iterates over the devices of the circuit

(2) Signature: *[const,iter]* Device **each_device**

Description: Iterates over the devices of the circuit (const version)

This constness variant has been introduced in version 0.26.8

each_net

(1) Signature: *[iter]* Net **each_net**

Description: Iterates over the nets of the circuit

(2) Signature: *[const,iter]* Net **each_net**

Description: Iterates over the nets of the circuit (const version)

This constness variant has been introduced in version 0.26.8

each_parent

(1) Signature: *[iter]* Circuit **each_parent**

Description: Iterates over the parent circuits of this circuit

Child circuits are the ones that are referencing this circuit via subcircuits.

(2) Signature: *[const,iter]* Circuit **each_parent**

Description: Iterates over the parent circuits of this circuit (const version)

Child circuits are the ones that are referencing this circuit via subcircuits.

This constness variant has been introduced in version 0.26.8

each_pin

(1) Signature: *[iter]* Pin **each_pin**
Description: Iterates over the pins of the circuit

(2) Signature: *[const,iter]* Pin **each_pin**
Description: Iterates over the pins of the circuit (const version)

This constness variant has been introduced in version 0.26.8

each_ref

(1) Signature: *[iter]* SubCircuit **each_ref**
Description: Iterates over the subcircuit objects referencing this circuit

(2) Signature: *[const,iter]* SubCircuit **each_ref**
Description: Iterates over the subcircuit objects referencing this circuit (const version)

This constness variant has been introduced in version 0.26.8

each_subcircuit

(1) Signature: *[iter]* SubCircuit **each_subcircuit**
Description: Iterates over the subcircuits of the circuit

(2) Signature: *[const,iter]* SubCircuit **each_subcircuit**
Description: Iterates over the subcircuits of the circuit (const version)

This constness variant has been introduced in version 0.26.8

flatten_subcircuit

Signature: void **flatten_subcircuit** (SubCircuit ptr subcircuit)
Description: Flattens a subcircuit

This method will substitute the given subcircuit by its contents. The subcircuit is removed after this.

has_refs?

Signature: *[const]* bool **has_refs?**
Description: Returns a value indicating whether the circuit has references

A circuit has references if there is at least one subcircuit referring to it.

join_nets

Signature: void **join_nets** (Net ptr net, Net ptr with)
Description: Joins (connects) two nets into one

This method will connect the 'with' net with 'net' and remove 'with'.

This method has been introduced in version 0.26.4. Starting with version 0.28.13, net names will be formed from both input names, combining them with as a comma-separated list.

name

Signature: *[const]* string **name**
Description: Gets the name of the circuit

Python specific notes:
The object exposes a readable attribute 'name'. This is the getter.

name=

Signature: void **name=** (string name)
Description: Sets the name of the circuit

Python specific notes:

	The object exposes a writable attribute 'name'. This is the setter.
net_by_cluster_id	**Signature**: Net ptr **net_by_cluster_id** (unsigned long cluster_id) **Description**: Gets the net object corresponding to a specific cluster ID If the ID is not a valid pin cluster ID, nil is returned.
net_by_name	**(1) Signature**: Net ptr **net_by_name** (string name) **Description**: Gets the net object for a given name. If the ID is not a valid net name, nil is returned. **(2) Signature**: *[const]* const Net ptr **net_by_name** (string name) **Description**: Gets the net object for a given name (const version). If the ID is not a valid net name, nil is returned. This constness variant has been introduced in version 0.26.8
net_for_pin	**(1) Signature**: Net ptr **net_for_pin** (unsigned long pin_id) **Description**: Gets the net object attached to a specific pin. This is the net object inside the circuit which attaches to the given outward-bound pin. This method returns nil if the pin is not connected or the pin ID is invalid. **(2) Signature**: *[const]* const Net ptr **net_for_pin** (unsigned long pin_id) **Description**: Gets the net object attached to a specific pin (const version). This is the net object inside the circuit which attaches to the given outward-bound pin. This method returns nil if the pin is not connected or the pin ID is invalid. This constness variant has been introduced in version 0.26.8 **(3) Signature**: Net ptr **net_for_pin** (const Pin ptr pin) **Description**: Gets the net object attached to a specific pin. This is the net object inside the circuit which attaches to the given outward-bound pin. This method returns nil if the pin is not connected or the pin object is nil. **(4) Signature**: *[const]* const Net ptr **net_for_pin** (const Pin ptr pin) **Description**: Gets the net object attached to a specific pin (const version). This is the net object inside the circuit which attaches to the given outward-bound pin. This method returns nil if the pin is not connected or the pin object is nil. This constness variant has been introduced in version 0.26.8
netlist	**(1) Signature**: Netlist ptr **netlist** **Description**: Gets the netlist object the circuit lives in **(2) Signature**: *[const]* const Netlist ptr **netlist** **Description**: Gets the netlist object the circuit lives in (const version) This constness variant has been introduced in version 0.26.8

nets_by_name

(1) Signature: Net ptr[] **nets_by_name** (string name_pattern)

Description: Gets the net objects for a given name filter.

The name filter is a glob pattern. This method will return all Net objects matching the glob pattern.

This method has been introduced in version 0.27.3.

(2) Signature: *[const]* const Net ptr[] **nets_by_name** (string name_pattern)

Description: Gets the net objects for a given name filter (const version).

The name filter is a glob pattern. This method will return all Net objects matching the glob pattern.

This constness variant has been introduced in version 0.27.3

pin_by_id

(1) Signature: Pin ptr **pin_by_id** (unsigned long id)

Description: Gets the Pin object corresponding to a specific ID

If the ID is not a valid pin ID, nil is returned.

(2) Signature: *[const]* const Pin ptr **pin_by_id** (unsigned long id)

Description: Gets the Pin object corresponding to a specific ID (const version)

If the ID is not a valid pin ID, nil is returned.

This constness variant has been introduced in version 0.26.8

pin_by_name

(1) Signature: Pin ptr **pin_by_name** (string name)

Description: Gets the Pin object corresponding to a specific name

If the ID is not a valid pin name, nil is returned.

(2) Signature: *[const]* const Pin ptr **pin_by_name** (string name)

Description: Gets the Pin object corresponding to a specific name (const version)

If the ID is not a valid pin name, nil is returned.

This constness variant has been introduced in version 0.26.8

pin_count

Signature: *[const]* unsigned long **pin_count**

Description: Gets the number of pins in the circuit

purge_nets

Signature: void **purge_nets**

Description: Purges floating nets.

Floating nets are nets with no device or subcircuit attached to. Such floating nets are removed in this step. If these nets are connected outward to a circuit pin, this circuit pin is also removed.

purge_nets_keep_pins

Signature: void **purge_nets_keep_pins**

Description: Purges floating nets but keep pins.

This method will remove floating nets like purge_nets, but if these nets are attached to a pin, the pin will be left disconnected from any net.

This method has been introduced in version 0.26.2.

remove_device	**Signature**: void **remove_device** (Device ptr device) **Description**: Removes the given device from the circuit
remove_net	**Signature**: void **remove_net** (Net ptr net) **Description**: Removes the given net from the circuit
remove_pin	**Signature**: void **remove_pin** (unsigned long id) **Description**: Removes the pin with the given ID from the circuit This method has been introduced in version 0.26.2.
remove_subcircuit	**Signature**: void **remove_subcircuit** (SubCircuit ptr subcircuit) **Description**: Removes the given subcircuit from the circuit
rename_pin	**Signature**: void **rename_pin** (unsigned long id, string new_name) **Description**: Renames the pin with the given ID to 'new_name' This method has been introduced in version 0.26.8.
subcircuit_by_id	**(1) Signature**: SubCircuit ptr **subcircuit_by_id** (unsigned long id) **Description**: Gets the subcircuit object for a given ID. If the ID is not a valid subcircuit ID, nil is returned. **(2) Signature**: *[const]* const SubCircuit ptr **subcircuit_by_id** (unsigned long id) **Description**: Gets the subcircuit object for a given ID (const version). If the ID is not a valid subcircuit ID, nil is returned. This constness variant has been introduced in version 0.26.8
subcircuit_by_name	**(1) Signature**: SubCircuit ptr **subcircuit_by_name** (string name) **Description**: Gets the subcircuit object for a given name. If the ID is not a valid subcircuit name, nil is returned. **(2) Signature**: *[const]* const SubCircuit ptr **subcircuit_by_name** (string name) **Description**: Gets the subcircuit object for a given name (const version). If the ID is not a valid subcircuit name, nil is returned. This constness variant has been introduced in version 0.26.8

4.134. API reference - Class Netlist

Notation used in Ruby API documentation

Module: db

Description: The netlist top-level class

A netlist is a hierarchical structure of circuits. At least one circuit is the top-level circuit, other circuits may be referenced as subcircuits. Circuits are created with create_circuit and are represented by objects of the Circuit class.

Beside circuits, the netlist manages device classes. Device classes describe specific types of devices. Device classes are represented by objects of the DeviceClass class and are created using create_device_class.

The netlist class has been introduced with version 0.26.

Public constructors

new Netlist ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**add**	(Circuit ptr circuit)	Adds the circuit to the netlist
	void	**add**	(DeviceClass ptr device_class)	Adds the device class to the netlist
	void	**assign**	(const Netlist other)	Assigns another object to self
	void	**blank_circuit**	(string pattern)	Blanks circuits matching a certain pattern
	void	**case_sensitive=**	(bool cs)	Sets a value indicating whether the netlist names are case sensitive
	Circuit ptr	**circuit_by_cell_index**	(unsigned int cell_index)	Gets the circuit object for a given cell index.
[const]	const Circuit ptr	**circuit_by_cell_index**	(unsigned int cell_index)	Gets the circuit object for a given cell index (const version).
	Circuit ptr	**circuit_by_name**	(string name)	Gets the circuit object for a given name.

[const]	const Circuit ptr	**circuit_by_name**	(string name)	Gets the circuit object for a given name (const version).
	Circuit ptr[]	**circuits_by_name**	(string name_pattern)	Gets the circuit objects for a given name filter.
[const]	const Circuit ptr[]	**circuits_by_name**	(string name_pattern)	Gets the circuit objects for a given name filter (const version).
	void	**combine_devices**		Combines devices where possible
	DeviceClass ptr	**device_class_by_name**	(string name)	Gets the device class for a given name.
[const]	const DeviceClass ptr	**device_class_by_name**	(string name)	Gets the device class for a given name (const version).
[const]	new Netlist ptr	**dup**		Creates a copy of self
[iter]	Circuit	**each_circuit**		Iterates over the circuits of the netlist
[const,iter]	Circuit	**each_circuit**		Iterates over the circuits of the netlist (const version)
[iter]	Circuit	**each_circuit_bottom_up**		Iterates over the circuits bottom-up
[const,iter]	Circuit	**each_circuit_bottom_up**		Iterates over the circuits bottom-up (const version)
[iter]	Circuit	**each_circuit_top_down**		Iterates over the circuits top-down
[const,iter]	Circuit	**each_circuit_top_down**		Iterates over the circuits top-down (const version)
[iter]	DeviceClass	**each_device_class**		Iterates over the device classes of the netlist
[const,iter]	DeviceClass	**each_device_class**		Iterates over the device classes of the netlist (const version)
	void	**flatten**		Flattens all circuits of the netlist
	void	**flatten_circuit**	(Circuit ptr circuit)	Flattens a subcircuit
	void	**flatten_circuit**	(string pattern)	Flattens circuits matching a certain pattern
	void	**flatten_circuits**	(Circuit ptr[] circuits)	Flattens all given circuits of the netlist
	void	**from_s**	(string str)	Reads the netlist from a string representation.
[const]	bool	**is_case_sensitive?**		Returns a value indicating whether the netlist names are case sensitive
	void	**make_top_level_pins**		Creates pins for top-level circuits.
	Net ptr[]	**nets_by_name**	(string name_pattern)	Gets the net objects for a given name filter.

[const]	const Net ptr[]	**nets_by_name**	(string name_pattern)	Gets the net objects for a given name filter (const version).
	void	**purge**		Purge unused nets, circuits and subcircuits.
	void	**purge_circuit**	(Circuit ptr circuit)	Removes the given circuit object and all child circuits which are not used otherwise from the netlist
	void	**purge_nets**		Purges floating nets.
	void	**read**	(string file, NetlistReader ptr reader)	Writes the netlist to the given file using the given reader object to parse the file
	void	**remove**	(Circuit ptr circuit)	Removes the given circuit object from the netlist
	void	**remove**	(DeviceClass ptr device_class)	Removes the given device class object from the netlist
	void	**simplify**		Convenience method that combines the simplification.
[const]	string	**to_s**		Converts the netlist to a string representation.
[const]	unsigned long	**top_circuit_count**		Gets the number of top circuits.
[const]	void	**write**	(string file, NetlistWriter ptr writer, string description =)	Writes the netlist to the given file using the given writer object to format the file

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void _**create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

add

(1) Signature: void **add** (Circuit ptr circuit)

Description: Adds the circuit to the netlist

This method will add the given circuit object to the netlist. After the circuit has been added, it will be owned by the netlist.

(2) Signature: void **add** (DeviceClass ptr device_class)

Description: Adds the device class to the netlist

This method will add the given device class object to the netlist. After the device class has been added, it will be owned by the netlist.

assign

Signature: void **assign** (const Netlist other)

Description: Assigns another object to self

blank_circuit

Signature: void **blank_circuit** (string pattern)

Description: Blanks circuits matching a certain pattern

This method will erase everything from inside the circuits matching the given pattern. It will only leave pins which are not connected to any net. Hence, this method forms 'abstract' or black-box circuits which can be instantiated through subcircuits like the former ones, but are empty shells. The name pattern is a glob expression. For example, 'blank_circuit("np*")' will blank out all circuits with names starting with 'np'.

For more details see Circuit#blank which is the corresponding method on the actual object.

case_sensitive=

Signature: void **case_sensitive=** (bool cs)

Description: Sets a value indicating whether the netlist names are case sensitive

This method has been added in version 0.27.3.

Python specific notes:
The object exposes a writable attribute 'case_sensitive'. This is the setter.

circuit_by_cell_index

(1) Signature: Circuit ptr **circuit_by_cell_index** (unsigned int cell_index)

Description: Gets the circuit object for a given cell index.

If the cell index is not valid or no circuit is registered with this index, nil is returned.

(2) Signature: *[const]* const Circuit ptr **circuit_by_cell_index** (unsigned int cell_index)

Description: Gets the circuit object for a given cell index (const version).

If the cell index is not valid or no circuit is registered with this index, nil is returned.

This constness variant has been introduced in version 0.26.8.

circuit_by_name

(1) Signature: Circuit ptr **circuit_by_name** (string name)

Description: Gets the circuit object for a given name.

If the name is not a valid circuit name, nil is returned.

(2) Signature: *[const]* const Circuit ptr **circuit_by_name** (string name)

Description: Gets the circuit object for a given name (const version).

If the name is not a valid circuit name, nil is returned.

This constness variant has been introduced in version 0.26.8.

circuits_by_name

(1) Signature: Circuit ptr[] **circuits_by_name** (string name_pattern)

Description: Gets the circuit objects for a given name filter.

The name filter is a glob pattern. This method will return all Circuit objects matching the glob pattern.

This method has been introduced in version 0.26.4.

(2) Signature: *[const]* const Circuit ptr[] **circuits_by_name** (string name_pattern)

Description: Gets the circuit objects for a given name filter (const version).

The name filter is a glob pattern. This method will return all Circuit objects matching the glob pattern.

This constness variant has been introduced in version 0.26.8.

combine_devices

Signature: void **combine_devices**

Description: Combines devices where possible

This method will combine devices that can be combined according to their device classes 'combine_devices' method. For example, serial or parallel resistors can be combined into a single resistor.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

device_class_by_name

(1) Signature: DeviceClass ptr **device_class_by_name** (string name)

Description: Gets the device class for a given name.

If the name is not a valid device class name, nil is returned.

(2) Signature: *[const]* const DeviceClass ptr **device_class_by_name** (string name)

Description: Gets the device class for a given name (const version).

If the name is not a valid device class name, nil is returned.

This constness variant has been introduced in version 0.26.8.

dup

Signature: *[const]* new Netlist ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

each_circuit

(1) Signature: *[iter]* Circuit **each_circuit**

Description: Iterates over the circuits of the netlist

(2) Signature: *[const,iter]* Circuit **each_circuit**

Description: Iterates over the circuits of the netlist (const version)

This constness variant has been introduced in version 0.26.8.

each_circuit_bottom_up

(1) Signature: *[iter]* Circuit **each_circuit_bottom_up**

Description: Iterates over the circuits bottom-up

Iterating bottom-up means the parent circuits come after the child circuits. This is the basically the reverse order as delivered by each_circuit_top_down.

(2) Signature: *[const,iter]* Circuit **each_circuit_bottom_up**

Description: Iterates over the circuits bottom-up (const version)

Iterating bottom-up means the parent circuits come after the child circuits. This is the basically the reverse order as delivered by each_circuit_top_down.

This constness variant has been introduced in version 0.26.8.

each_circuit_top_down

(1) Signature: *[iter]* Circuit **each_circuit_top_down**

Description: Iterates over the circuits top-down

Iterating top-down means the parent circuits come before the child circuits. The first top_circuit_count circuits are top circuits - i.e. those which are not referenced by other circuits.

(2) Signature: *[const,iter]* Circuit **each_circuit_top_down**

Description: Iterates over the circuits top-down (const version)

Iterating top-down means the parent circuits come before the child circuits. The first top_circuit_count circuits are top circuits - i.e. those which are not referenced by other circuits.

This constness variant has been introduced in version 0.26.8.

each_device_class

(1) Signature: *[iter]* DeviceClass **each_device_class**

Description: Iterates over the device classes of the netlist

(2) Signature: *[const,iter]* DeviceClass **each_device_class**

Description: Iterates over the device classes of the netlist (const version)

This constness variant has been introduced in version 0.26.8.

flatten

Signature: void **flatten**

Description: Flattens all circuits of the netlist

After calling this method, only the top circuits will remain.

flatten_circuit

(1) Signature: void **flatten_circuit** (Circuit ptr circuit)

Description: Flattens a subcircuit

This method will substitute all instances (subcircuits) of the given circuit by its contents. After this, the circuit is removed.

(2) Signature: void **flatten_circuit** (string pattern)

Description: Flattens circuits matching a certain pattern

This method will substitute all instances (subcircuits) of all circuits with names matching the given name pattern. The name pattern is a glob expression. For example, 'flatten_circuit("np*")' will flatten all circuits with names starting with 'np'.

flatten_circuits

Signature: void **flatten_circuits** (Circuit ptr[] circuits)

Description: Flattens all given circuits of the netlist

This method is equivalent to calling flatten_circuit for all given circuits, but more efficient.

This method has been introduced in version 0.26.1

from_s

Signature: void **from_s** (string str)

Description: Reads the netlist from a string representation.

This method is intended for test purposes mainly. It turns a string returned by to_s back into a netlist. Note that the device classes must be created before as they are not persisted inside the string.

is_case_sensitive?

Signature: *[const]* bool **is_case_sensitive?**

Description: Returns a value indicating whether the netlist names are case sensitive

This method has been added in version 0.27.3.

Python specific notes:
The object exposes a readable attribute 'case_sensitive'. This is the getter.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

make_top_level_pins

Signature: void **make_top_level_pins**

Description: Creates pins for top-level circuits.

This method will turn all named nets of top-level circuits (such that are not referenced by subcircuits) into pins. This method can be used before purge to avoid that purge will remove nets which are directly connecting to subcircuits.

nets_by_name

(1) Signature: Net ptr[] **nets_by_name** (string name_pattern)

Description: Gets the net objects for a given name filter.

The name filter is a glob pattern. This method will return all Net objects matching the glob pattern.

This method has been introduced in version 0.28.4.

(2) Signature: *[const]* const Net ptr[] **nets_by_name** (string name_pattern)

Description: Gets the net objects for a given name filter (const version).

The name filter is a glob pattern. This method will return all Net objects matching the glob pattern.

This constness variant has been introduced in version 0.28.4.

new

Signature: *[static]* new Netlist ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

purge

Signature: void **purge**

Description: Purge unused nets, circuits and subcircuits.

This method will purge all nets which return floating == true. Circuits which don't have any nets (or only floating ones) and removed. Their subcircuits are disconnected. This method respects the Circuit#dont_purge attribute and will never delete circuits with this flag set.

purge_circuit

Signature: void **purge_circuit** (Circuit ptr circuit)

Description: Removes the given circuit object and all child circuits which are not used otherwise from the netlist

After the circuit has been removed, the object becomes invalid and cannot be used further. A circuit with references (see has_refs?) should not be removed as the subcircuits calling it would afterwards point to nothing.

purge_nets

Signature: void **purge_nets**

Description: Purges floating nets.

Floating nets can be created as effect of reconnections of devices or pins. This method will eliminate all nets that make less than two connections.

read

Signature: void **read** (string file, NetlistReader ptr reader)

Description: Writes the netlist to the given file using the given reader object to parse the file

See NetlistSpiceReader for an example for a parser.

remove

(1) Signature: void **remove** (Circuit ptr circuit)

Description: Removes the given circuit object from the netlist

After the circuit has been removed, the object becomes invalid and cannot be used further. A circuit with references (see has_refs?) should not be removed as the subcircuits calling it would afterwards point to nothing.

(2) Signature: void **remove** (DeviceClass ptr device_class)

Description: Removes the given device class object from the netlist

After the object has been removed, it becomes invalid and cannot be used further. Use this method with care as it may corrupt the internal structure of the netlist. Only use this method when device refers to this device class.

simplify

Signature: void **simplify**

Description: Convenience method that combines the simplification.

This method is a convenience method that runs make_top_level_pins, purge, combine_devices and purge_nets.

to_s

Signature: *[const]* string **to_s**

Description: Converts the netlist to a string representation.

This method is intended for test purposes mainly.

Python specific notes:
This method is also available as 'str(object)'.

top_circuit_count

Signature: *[const]* unsigned long **top_circuit_count**

Description: Gets the number of top circuits.

Top circuits are those which are not referenced by other circuits via subcircuits. A well-formed netlist has a single top circuit.

write

Signature: *[const]* void **write** (string file, NetlistWriter ptr writer, string description =)

Description: Writes the netlist to the given file using the given writer object to format the file

See NetlistSpiceWriter for an example for a formatter. The description is an arbitrary text which will be put into the file somewhere at the beginning.

4.135. API reference - Class NetlistSpiceWriterDelegate

Notation used in Ruby API documentation

Module: db

Description: Provides a delegate for the SPICE writer for doing special formatting for devices

Supply a customized class to provide a specialized writing scheme for devices. You need a customized class if you want to implement special devices or you want to use subcircuits rather than the built-in devices.

See NetlistSpiceWriter for more details.

This class has been introduced in version 0.26.

Public constructors

new NetlistSpiceWriterDelegate ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const NetlistSpiceWriterD other)	Assigns another object to self
[const]	new NetlistSpiceWriterDelegate ptr	**dup**		Creates a copy of self
[const]	void	**emit_comment**	(string comment)	Writes the given comment into the file
[const]	void	**emit_line**	(string line)	Writes the given line into the file
[const]	string	**format_name**	(string name)	Formats the given name in a SPICE-compatible way
[const]	string	**net_to_string**	(const Net ptr net)	Gets the node ID for the given net
[virtual,const]	void	**write_device**	(Device device)	Inserts a text for the given device

[virtual,const]	void	**write_device_intro**	(DeviceClass device_class)	Inserts a text for the given device class
[virtual,const]	void	**write_header**		Writes the text at the beginning of the SPICE netlist

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const NetlistSpiceWriterDelegate other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new NetlistSpiceWriterDelegate ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

emit_comment

Signature: *[const]* void **emit_comment** (string comment)

Description: Writes the given comment into the file

emit_line

Signature: *[const]* void **emit_line** (string line)

Description: Writes the given line into the file

format_name

Signature: *[const]* string **format_name** (string name)

Description: Formats the given name in a SPICE-compatible way

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

net_to_string

Signature: *[const]* string **net_to_string** (const Net ptr net)

Description: Gets the node ID for the given net

The node ID is a numeric string instead of the full name of the net. Numeric IDs are used within SPICE netlist because they are usually shorter.

new

Signature: *[static]* new NetlistSpiceWriterDelegate ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

write_device

Signature: *[virtual,const]* void **write_device** (Device device)

Description: Inserts a text for the given device

Reimplement this method to write the given device in the desired way. The default implementation will utilize the device class information to write native SPICE elements for the devices.

write_device_intro

Signature: *[virtual,const]* void **write_device_intro** (DeviceClass device_class)

Description: Inserts a text for the given device class

Reimplement this method to insert your own text at the beginning of the file for the given device class

write_header

Signature: *[virtual,const]* void **write_header**

Description: Writes the text at the beginning of the SPICE netlist

Reimplement this method to insert your own text at the beginning of the file

4.136. API reference - Class NetlistWriter

Notation used in Ruby API documentation

Module: db

Description: Base class for netlist writers

This class is provided as a base class for netlist writers. It is not intended for reimplementation on script level, but used internally as an interface.

This class has been introduced in version 0.26.

Public constructors

new NetlistWriter ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference
	void	**_manage**	Marks the object as managed by the script side.
	void	**_unmanage**	Marks the object as no longer owned by the script side.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new NetlistWriter ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

4.137. API reference - Class NetlistSpiceWriter

Notation used in Ruby API documentation

Module: db

Description: Implements a netlist writer for the SPICE format.

Class hierarchy: NetlistSpiceWriter » NetlistWriter

Provide a delegate for customizing the way devices are written.

Use the SPICE writer like this:

```
writer = RBA::NetlistSpiceWriter::new
netlist.write(path, writer)
```

You can give a custom description for the headline:

```
writer = RBA::NetlistSpiceWriter::new
netlist.write(path, writer, "A custom description")
```

To customize the output, you can use a device writer delegate. The delegate is an object of a class derived from NetlistSpiceWriterDelegate which reimplements several methods to customize the following parts:

- A global header (NetlistSpiceWriterDelegate#write_header): this method is called to print the part right after the headline
- A per-device class header (NetlistSpiceWriterDelegate#write_device_intro): this method is called for every device class and may print device-class specific headers (e.g. model definitions)
- Per-device output: this method (NetlistSpiceWriterDelegate#write_device): this method is called for every device and may print the device statement(s) in a specific way.

The delegate must use NetlistSpiceWriterDelegate#emit_line to print a line, NetlistSpiceWriterDelegate#emit_comment to print a comment etc. For more method see NetlistSpiceWriterDelegate.

A sample with a delegate is this:

```
class MyDelegate < RBA::NetlistSpiceWriterDelegate

  def write_header
    emit_line("*** My special header")
  end

  def write_device_intro(cls)
    emit_comment("My intro for class " + cls.name)
  end

  def write_device(dev)
    if dev.device_class.name != "MYDEVICE"
      emit_comment("Terminal #1: " + net_to_string(dev.net_for_terminal(0)))
      emit_comment("Terminal #2: " + net_to_string(dev.net_for_terminal(1)))
      super(dev)
      emit_comment("After device " + dev.expanded_name)
    else
      super(dev)
    end
  end

end
```

```
# write the netlist with delegate:
writer = RBA::NetlistSpiceWriter::new(MyDelegate::new)
netlist.write(path, writer)
```

This class has been introduced in version 0.26.

Public constructors

new NetlistSpiceWriter ptr	**new**		Creates a new writer without delegate.
new NetlistSpiceWriter ptr	**new**	(NetlistSpiceWriterDelegate ptr delegate)	Creates a new writer with a delegate.

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const NetlistSpice other)	Assigns another object to self
[const]	new NetlistSpiceWriter ptr	**dup**		Creates a copy of self
	void	**use_net_names=**	(bool f)	Sets a value indicating whether to use net names (true) or net numbers (false).
[const]	bool	**use_net_names?**		Gets a value indicating whether to use net names (true) or net numbers (false).
	void	**with_comments=**	(bool f)	Sets a value indicating whether to embed comments for position etc. (true) or not (false).
[const]	bool	**with_comments?**		Gets a value indicating whether to embed comments for position etc. (true) or not (false).

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

	Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
_destroy	**Signature**: void **_destroy** **Description**: Explicitly destroys the object Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
_destroyed?	**Signature**: *[const]* bool **_destroyed?** **Description**: Returns a value indicating whether the object was already destroyed This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
_is_const_object?	**Signature**: *[const]* bool **_is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference This method returns true, if self is a const reference. In that case, only const methods may be called on self.
_manage	**Signature**: void **_manage** **Description**: Marks the object as managed by the script side. After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required. Usually it's not required to call this method. It has been introduced in version 0.24.
_unmanage	**Signature**: void **_unmanage** **Description**: Marks the object as no longer owned by the script side. Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.
assign	**Signature**: void **assign** (const NetlistSpiceWriter other) **Description**: Assigns another object to self
dup	**Signature**: *[const]* new NetlistSpiceWriter ptr **dup** **Description**: Creates a copy of self **Python specific notes:** This method also implements '__copy__' and '__deepcopy__'.
new	**(1) Signature**: *[static]* new NetlistSpiceWriter ptr **new** **Description**: Creates a new writer without delegate.

	Python specific notes: This method is the default initializer of the object. **(2) Signature**: *[static]* new NetlistSpiceWriter ptr **new** (NetlistSpiceWriterDelegate ptr delegate) **Description**: Creates a new writer with a delegate. **Python specific notes:** This method is the default initializer of the object.
use_net_names=	**Signature**: void **use_net_names=** (bool f) **Description**: Sets a value indicating whether to use net names (true) or net numbers (false). The default is to use net numbers. **Python specific notes:** The object exposes a writable attribute 'use_net_names'. This is the setter.
use_net_names?	**Signature**: *[const]* bool **use_net_names?** **Description**: Gets a value indicating whether to use net names (true) or net numbers (false). **Python specific notes:** The object exposes a readable attribute 'use_net_names'. This is the getter.
with_comments=	**Signature**: void **with_comments=** (bool f) **Description**: Sets a value indicating whether to embed comments for position etc. (true) or not (false). The default is to embed comments. **Python specific notes:** The object exposes a writable attribute 'with_comments'. This is the setter.
with_comments?	**Signature**: *[const]* bool **with_comments?** **Description**: Gets a value indicating whether to embed comments for position etc. (true) or not (false). **Python specific notes:** The object exposes a readable attribute 'with_comments'. This is the getter.

4.138. API reference - Class NetlistReader

Notation used in Ruby API documentation

Module: db

Description: Base class for netlist readers

This class is provided as a base class for netlist readers. It is not intended for reimplementation on script level, but used internally as an interface.

This class has been introduced in version 0.26.

Public constructors

new NetlistReader ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference
	void	**_manage**	Marks the object as managed by the script side.
	void	**_unmanage**	Marks the object as no longer owned by the script side.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

	Use of this method is deprecated. Use _destroyed? instead This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
is_const_object?	**Signature**: *[const]* bool **is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.
new	**Signature**: *[static]* new NetlistReader ptr **new** **Description**: Creates a new object of this class **Python specific notes:** This method is the default initializer of the object.

4.139. API reference - Class ParseElementComponentsData

Notation used in Ruby API documentation

Module: db

Description: Supplies the return value for \NetlistSpiceReaderDelegate#parse_element_components.

This is a structure with two members: 'strings' for the string arguments and 'parameters' for the named arguments.

This helper class has been introduced in version 0.27.1. Starting with version 0.28.6, named parameters can be string types too.

Public constructors

new ParseElementComponentsData ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const ParseElementC other)	Assigns another object to self
[const]	new ParseElementComponentsData ptr	**dup**		Creates a copy of self
[const]	map<string,variant>	**parameters**		Gets the (named) parameters
	void	**parameters=**	(map<string,variant> dict)	Sets the (named) parameters
[const]	string[]	**strings**		Gets the (unnamed) string parameters
	void	**strings=**	(string[] list)	Sets the (unnamed) string parameters

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead

[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const ParseElementComponentsData other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new ParseElementComponentsData ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new ParseElementComponentsData ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

parameters

Signature: *[const]* map<string,variant> **parameters**

Description: Gets the (named) parameters

Named parameters are typically (but not neccessarily) numerical, like 'w=0.15u'.

Python specific notes:
The object exposes a readable attribute 'parameters'. This is the getter.

parameters=

Signature: void **parameters=** (map<string,variant> dict)

Description: Sets the (named) parameters

Python specific notes:
The object exposes a writable attribute 'parameters'. This is the setter.

strings

Signature: *[const]* string[] **strings**

Description: Gets the (unnamed) string parameters

These parameters are typically net names or model name.

Python specific notes:
The object exposes a readable attribute 'strings'. This is the getter.

strings=

Signature: void **strings=** (string[] list)

Description: Sets the (unnamed) string parameters

Python specific notes:
The object exposes a writable attribute 'strings'. This is the setter.

4.140. API reference - Class ParseElementData

Notation used in Ruby API documentation

Module: db

Description: Supplies the return value for \NetlistSpiceReaderDelegate#parse_element.

This is a structure with four members: 'model_name' for the model name, 'value' for the default numerical value, 'net_names' for the net names and 'parameters' for the named parameters.

This helper class has been introduced in version 0.27.1. Starting with version 0.28.6, named parameters can be string types too.

Public constructors

new ParseElementData ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const ParseElementD other)	Assigns another object to self
[const]	new ParseElementData ptr	**dup**		Creates a copy of self
[const]	string	**model_name**		Gets the model name
	void	**model_name=**	(string m)	Sets the model name
[const]	string[]	**net_names**		Gets the net names
	void	**net_names=**	(string[] list)	Sets the net names
[const]	map<string,variant>	**parameters**		Gets the (named) parameters
	void	**parameters=**	(map<string,variant> dict)	Sets the (named) parameters
[const]	double	**value**		Gets the value
	void	**value=**	(double v)	Sets the value

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method

will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const ParseElementData other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new ParseElementData ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

model_name

Signature: *[const]* string **model_name**

Description: Gets the model name

Python specific notes:
The object exposes a readable attribute 'model_name'. This is the getter.

model_name=

Signature: void **model_name=** (string m)

Description: Sets the model name

Python specific notes:

	The object exposes a writable attribute 'model_name'. This is the setter.
net_names	**Signature**: *[const]* string[] **net_names** **Description**: Gets the net names **Python specific notes:** The object exposes a readable attribute 'net_names'. This is the getter.
net_names=	**Signature**: void **net_names=** (string[] list) **Description**: Sets the net names **Python specific notes:** The object exposes a writable attribute 'net_names'. This is the setter.
new	**Signature**: *[static]* new ParseElementData ptr **new** **Description**: Creates a new object of this class **Python specific notes:** This method is the default initializer of the object.
parameters	**Signature**: *[const]* map<string,variant> **parameters** **Description**: Gets the (named) parameters **Python specific notes:** The object exposes a readable attribute 'parameters'. This is the getter.
parameters=	**Signature**: void **parameters=** (map<string,variant> dict) **Description**: Sets the (named) parameters **Python specific notes:** The object exposes a writable attribute 'parameters'. This is the setter.
value	**Signature**: *[const]* double **value** **Description**: Gets the value **Python specific notes:** The object exposes a readable attribute 'value'. This is the getter.
value=	**Signature**: void **value=** (double v) **Description**: Sets the value **Python specific notes:** The object exposes a writable attribute 'value'. This is the setter.

4.141. API reference - Class NetlistSpiceReaderDelegate

Notation used in Ruby API documentation

Module: db

Description: Provides a delegate for the SPICE reader for translating device statements

Supply a customized class to provide a specialized reading scheme for devices. You need a customized class if you want to implement device reading from model subcircuits or to translate device parameters.

See NetlistSpiceReader for more details.

This class has been introduced in version 0.26.

Public constructors

new NetlistSpiceReaderDelegate ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	void	**apply_parameter_scal**	(Device ptr device)	Applies parameter scaling to the given device
	void	**assign**	(const NetlistSpiceReaderDelegate other)	Assigns another object to self
[virtual]	bool	**control_statement**	(string line)	Receives control statements not understood by the standard reader
[const]	new NetlistSpiceReaderDelegate ptr	**dup**		Creates a copy of self
[virtual]	bool	**element**	(Circuit ptr circuit, string element, string name, string model, double value, Net ptr[] nets, map<string,variant> parameters)	Makes a device from an element line

	void	**error**	(string msg)	Issues an error with the given message.
[virtual]	void	**finish**	(Netlist ptr netlist)	This method is called when the reader is done reading a netlist successfully
[const]	double	**get_scale**		Gets the scale factor set with '.options scale=...'
[virtual]	ParseElementData	**parse_element**	(string s, string element)	Parses an element card
	ParseElementComponentsData	**parse_element_components**	(string s, map<string,variant> variables = {})	Parses a string into string and parameter components.
[virtual]	void	**start**	(Netlist ptr netlist)	This method is called when the reader starts reading a netlist
[virtual]	string	**translate_net_name**	(string net_name)	Translates a net name from the raw net name to the true net name
	variant	**value_from_string**	(string s, map<string,variant> variables = {})	Translates a string into a value
[const]	map<string,variant>	**variables**		Gets the variables defined inside the SPICE file during execution of 'parse_element'
[virtual]	bool	**wants_subcircuit**	(string circuit_name)	Returns true, if the delegate wants subcircuit elements with this name

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

apply_parameter_scaling

Signature: *[const]* void **apply_parameter_scaling** (Device ptr device)

Description: Applies parameter scaling to the given device

Applies SI scaling (according to the parameter's si_scaling attribute) and geometry scaling (according to the parameter's geo_scale_exponent attribute) to the device parameters. Use this method of finish the device when you have created a custom device yourself.

The geometry scale is taken from the '.options scale=...' control statement.

This method has been introduced in version 0.28.6.

assign

Signature: void **assign** (const NetlistSpiceReaderDelegate other)

Description: Assigns another object to self

control_statement

Signature: *[virtual]* bool **control_statement** (string line)

Description: Receives control statements not understood by the standard reader

When the reader encounters a control statement not understood by the parser, it will pass the line to the delegate using this method. The delegate can decide if it wants to read this statement. It should return true in this case.

This method has been introduced in version 0.27.1

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new NetlistSpiceReaderDelegate ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

element

Signature: *[virtual]* bool **element** (Circuit ptr circuit, string element, string name, string model, double value, Net ptr[] nets, map<string,variant> parameters)

Description: Makes a device from an element line

circuit:	The circuit that is currently read.
element:	The upper-case element code ("M", "R", ...).
name:	The element's name.
model:	The upper-case model name (may be empty).
value:	The default value (e.g. resistance for resistors) and may be zero.
nets:	The nets given in the element line.
parameters:	The parameters of the element statement (parameter names are upper case).

The default implementation will create corresponding devices for some known elements using the Spice writer's parameter conventions.

The method must return true, if the element was was understood and false otherwise.

Starting with version 0.28.6, the parameter values can be strings too.

error

Signature: void **error** (string msg)

Description: Issues an error with the given message.

Use this method to generate an error.

finish

Signature: *[virtual]* void **finish** (Netlist ptr netlist)

Description: This method is called when the reader is done reading a netlist successfully

get_scale

Signature: *[const]* double **get_scale**

Description: Gets the scale factor set with '.options scale=...'

This method has been introduced in version 0.28.6.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new NetlistSpiceReaderDelegate ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

parse_element

Signature: *[virtual]* ParseElementData **parse_element** (string s, string element)

Description: Parses an element card

s:	The specification part of the element line (the part after element code and name).
element:	The upper-case element code ("M", "R", ...).
Returns:	A ParseElementData object with the parts of the element.

This method receives a string with the element specification and the element code. It is supposed to parse the element line and return a model name, a value, a list of net names and a parameter value dictionary.

'parse_element' is called on every element card. The results of this call go into the element method to actually create the device. This method can be reimplemented to support other flavors of SPICE.

This method has been introduced in version 0.27.1

parse_element_components

Signature: ParseElementComponentsData **parse_element_components** (string s, map<string,variant> variables = {})

Description: Parses a string into string and parameter components.

This method is provided to simplify the implementation of 'parse_element'. It takes a string and splits it into string arguments and parameter values. For example, 'a b c=6' renders two string arguments in 'nn' and one parameter ('C'->6.0). It returns data ParseElementComponentsData object with the strings and parameters. The parameter names are already translated to upper case.

The variables dictionary defines named variables with the given values.

This method has been introduced in version 0.27.1. The variables argument has been added in version 0.28.6.

start

Signature: *[virtual]* void **start** (Netlist ptr netlist)

Description: This method is called when the reader starts reading a netlist

translate_net_name

Signature: *[virtual]* string **translate_net_name** (string net_name)

Description: Translates a net name from the raw net name to the true net name

The default implementation will replace backslash sequences by the corresponding character. 'translate_net_name' is called before a net name is turned into a net object. The method can be reimplemented to supply a different translation scheme for net names. For example, to translate special characters.

This method has been introduced in version 0.27.1

value_from_string

Signature: variant **value_from_string** (string s, map<string,variant> variables = {})

Description: Translates a string into a value

This function simplifies the implementation of SPICE readers by providing a translation of a unit-annotated string into double values. For example, '1k' is translated to 1000.0. In addition, simple formula evaluation is supported, e.g '(1+3)*2' is translated into 8.0.

The variables dictionary defines named variables with the given values.

This method has been introduced in version 0.27.1. The variables argument has been added in version 0.28.6.

variables

Signature: *[const]* map<string,variant> **variables**

Description: Gets the variables defined inside the SPICE file during execution of 'parse_element'

In order to evaluate formulas, this method allows accessing the variables that are present during the execution of the SPICE reader.

This method has been introduced in version 0.28.6.

wants_subcircuit

Signature: *[virtual]* bool **wants_subcircuit** (string circuit_name)

Description: Returns true, if the delegate wants subcircuit elements with this name

The name is always upper case.

4.142. API reference - Class NetlistSpiceReader

Notation used in Ruby API documentation

Module: db

Description: Implements a netlist Reader for the SPICE format.

Class hierarchy: NetlistSpiceReader » NetlistReader

Use the SPICE reader like this:

```
reader = RBA::NetlistSpiceReader::new
netlist = RBA::Netlist::new
netlist.read(path, reader)
```

The translation of SPICE elements can be tailored by providing a NetlistSpiceReaderDelegate class. This allows translating of device parameters and mapping of some subcircuits to devices.

The following example is a delegate that turns subcircuits called HVNMOS and HVPMOS into MOS4 devices with the parameters scaled by 1.5:

```
class MyDelegate < RBA::NetlistSpiceReaderDelegate

  # says we want to catch these subcircuits as devices
  def wants_subcircuit(name)
    name == "HVNMOS" || name == "HVPMOS"
  end

  # translate the element
  def element(circuit, el, name, model, value, nets, params)

    if el != "X"
      # all other elements are left to the standard implementation
      return super
    end

    if nets.size != 4
      error("Subcircuit #{model} needs four nodes")
    end

    # provide a device class
    cls = circuit.netlist.device_class_by_name(model)
    if ! cls
      cls = RBA::DeviceClassMOS4Transistor::new
      cls.name = model
      circuit.netlist.add(cls)
    end

    # create a device
    device = circuit.create_device(cls, name)

    # and configure the device
    [ "S", "G", "D", "B" ].each_with_index do |t,index|
      device.connect_terminal(t, nets[index])
    end
    params.each do |p,value|
      device.set_parameter(p, value * 1.5)
    end

  end

end
```

```
# usage:

mydelegate = MyDelegate::new
reader = RBA::NetlistSpiceReader::new(mydelegate)

nl = RBA::Netlist::new
nl.read(input_file, reader)
```

A somewhat contrived example for using the delegate to translate net names is this:

```
class MyDelegate < RBA::NetlistSpiceReaderDelegate

  # translates 'VDD' to 'VXX' and leave all other net names as is:
  alias translate_net_name_org translate_net_name
  def translate_net_name(n)
    return n == "VDD" ? "VXX" : translate_net_name_org(n)}
  end

end
```

This class has been introduced in version 0.26. It has been extended in version 0.27.1.

Public constructors

new NetlistSpiceReader ptr	**new**		Creates a new reader.
new NetlistSpiceReader ptr	**new**	(NetlistSpiceReaderDelegate ptr delegate)	Creates a new reader with a delegate.

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference
	void	**_manage**	Marks the object as managed by the script side.
	void	**_unmanage**	Marks the object as no longer owned by the script side.

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

new

(1) Signature: *[static]* new NetlistSpiceReader ptr **new**

Description: Creates a new reader.

Python specific notes:
This method is the default initializer of the object.

(2) Signature: *[static]* new NetlistSpiceReader ptr **new** (NetlistSpiceReaderDelegate ptr delegate)

Description: Creates a new reader with a delegate.

Python specific notes:
This method is the default initializer of the object.

4.143. API reference - Class DeviceClassResistor

Notation used in Ruby API documentation

Module: db

Description: A device class for a resistor.

Class hierarchy: DeviceClassResistor » DeviceClass

This class describes a resistor. Resistors are defined by their combination behavior and the basic parameter 'R' which is the resistance in Ohm.

A resistor has two terminals, A and B. The parameters of a resistor are R (the value in Ohms), L and W (length and width in micrometers) and A and P (area and perimeter in square micrometers and micrometers respectively).

This class has been introduced in version 0.26.

Public methods

	void	**_assign**	(const DeviceClas other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new DeviceClassResistor ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.

Public static methods and constants

[static,const]	unsigned long	**PARAM_A**	A constant giving the parameter ID for parameter A
[static,const]	unsigned long	**PARAM_L**	A constant giving the parameter ID for parameter L
[static,const]	unsigned long	**PARAM_P**	A constant giving the parameter ID for parameter P
[static,const]	unsigned long	**PARAM_R**	A constant giving the parameter ID for parameter R
[static,const]	unsigned long	**PARAM_W**	A constant giving the parameter ID for parameter W

[static,const]	unsigned long	**TERMINAL_A**	A constant giving the terminal ID for terminal A
[static,const]	unsigned long	**TERMINAL_B**	A constant giving the terminal ID for terminal B

Detailed description

PARAM_A

Signature: *[static,const]* unsigned long **PARAM_A**

Description: A constant giving the parameter ID for parameter A

Python specific notes:
The object exposes a readable attribute 'PARAM_A'. This is the getter.

PARAM_L

Signature: *[static,const]* unsigned long **PARAM_L**

Description: A constant giving the parameter ID for parameter L

Python specific notes:
The object exposes a readable attribute 'PARAM_L'. This is the getter.

PARAM_P

Signature: *[static,const]* unsigned long **PARAM_P**

Description: A constant giving the parameter ID for parameter P

Python specific notes:
The object exposes a readable attribute 'PARAM_P'. This is the getter.

PARAM_R

Signature: *[static,const]* unsigned long **PARAM_R**

Description: A constant giving the parameter ID for parameter R

Python specific notes:
The object exposes a readable attribute 'PARAM_R'. This is the getter.

PARAM_W

Signature: *[static,const]* unsigned long **PARAM_W**

Description: A constant giving the parameter ID for parameter W

Python specific notes:
The object exposes a readable attribute 'PARAM_W'. This is the getter.

TERMINAL_A

Signature: *[static,const]* unsigned long **TERMINAL_A**

Description: A constant giving the terminal ID for terminal A

Python specific notes:
The object exposes a readable attribute 'TERMINAL_A'. This is the getter.

TERMINAL_B

Signature: *[static,const]* unsigned long **TERMINAL_B**

Description: A constant giving the terminal ID for terminal B

Python specific notes:
The object exposes a readable attribute 'TERMINAL_B'. This is the getter.

_assign

Signature: void **_assign** (const DeviceClassResistor other)

Description: Assigns another object to self

_create

Signature: void **_create**

Description: Ensures the C++ object is created

	Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
_destroy	**Signature**: void **_destroy** **Description**: Explicitly destroys the object Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
_destroyed?	**Signature**: *[const]* bool **_destroyed?** **Description**: Returns a value indicating whether the object was already destroyed This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
_dup	**Signature**: *[const]* new DeviceClassResistor ptr **_dup** **Description**: Creates a copy of self
_is_const_object?	**Signature**: *[const]* bool **_is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference This method returns true, if self is a const reference. In that case, only const methods may be called on self.
_manage	**Signature**: void **_manage** **Description**: Marks the object as managed by the script side. After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required. Usually it's not required to call this method. It has been introduced in version 0.24.
_unmanage	**Signature**: void **_unmanage** **Description**: Marks the object as no longer owned by the script side. Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.

4.144. API reference - Class DeviceClassResistorWithBulk

Notation used in Ruby API documentation

Module: db

Description: A device class for a resistor with a bulk terminal (substrate, well).

Class hierarchy: DeviceClassResistorWithBulk » DeviceClassResistor » DeviceClass

This class is similar to DeviceClassResistor, but provides an additional terminal (BULK) for the well or substrate the resistor is embedded in.

The additional terminal is 'W' for the well/substrate terminal.

This class has been introduced in version 0.26.

Public methods

	void	**_assign**	(const DeviceClass other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new DeviceClassResistorWith ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.

Public static methods and constants

[static,const]	unsigned long	**TERMINAL_W**	A constant giving the terminal ID for terminal W (well, bulk)

Detailed description

TERMINAL_W

Signature: *[static,const]* unsigned long **TERMINAL_W**

Description: A constant giving the terminal ID for terminal W (well, bulk)

Python specific notes:
The object exposes a readable attribute 'TERMINAL_W'. This is the getter.

_assign

Signature: void **_assign** (const DeviceClassResistorWithBulk other)

Description: Assigns another object to self

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_dup

Signature: *[const]* new DeviceClassResistorWithBulk ptr **_dup**

Description: Creates a copy of self

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

4.145. API reference - Class DeviceClassCapacitor

Notation used in Ruby API documentation

Module: db

Description: A device class for a capacitor.

Class hierarchy: DeviceClassCapacitor » DeviceClass

This describes a capacitor. Capacitors are defined by their combination behavior and the basic parameter 'C' which is the capacitance in Farad.

A capacitor has two terminals, A and B. The parameters of a capacitor are C (the value in Farad) and A and P (area and perimeter in square micrometers and micrometers respectively).

This class has been introduced in version 0.26.

Public methods

	void	**_assign**	(const DeviceClas other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new DeviceClassCapacitor ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.

Public static methods and constants

[static,const]	unsigned long	**PARAM_A**	A constant giving the parameter ID for parameter A
[static,const]	unsigned long	**PARAM_C**	A constant giving the parameter ID for parameter C
[static,const]	unsigned long	**PARAM_P**	A constant giving the parameter ID for parameter P
[static,const]	unsigned long	**TERMINAL_A**	A constant giving the terminal ID for terminal A
[static,const]	unsigned long	**TERMINAL_B**	A constant giving the terminal ID for terminal B

Detailed description

PARAM_A	**Signature**: *[static,const]* unsigned long **PARAM_A** **Description**: A constant giving the parameter ID for parameter A **Python specific notes:** The object exposes a readable attribute 'PARAM_A'. This is the getter.
PARAM_C	**Signature**: *[static,const]* unsigned long **PARAM_C** **Description**: A constant giving the parameter ID for parameter C **Python specific notes:** The object exposes a readable attribute 'PARAM_C'. This is the getter.
PARAM_P	**Signature**: *[static,const]* unsigned long **PARAM_P** **Description**: A constant giving the parameter ID for parameter P **Python specific notes:** The object exposes a readable attribute 'PARAM_P'. This is the getter.
TERMINAL_A	**Signature**: *[static,const]* unsigned long **TERMINAL_A** **Description**: A constant giving the terminal ID for terminal A **Python specific notes:** The object exposes a readable attribute 'TERMINAL_A'. This is the getter.
TERMINAL_B	**Signature**: *[static,const]* unsigned long **TERMINAL_B** **Description**: A constant giving the terminal ID for terminal B **Python specific notes:** The object exposes a readable attribute 'TERMINAL_B'. This is the getter.
_assign	**Signature**: void **_assign** (const DeviceClassCapacitor other) **Description**: Assigns another object to self
_create	**Signature**: void **_create** **Description**: Ensures the C++ object is created Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.

4.146. API reference - Class DeviceClassCapacitorWithBulk

Notation used in Ruby API documentation

Module: db

Description: A device class for a capacitor with a bulk terminal (substrate, well).

Class hierarchy: DeviceClassCapacitorWithBulk » DeviceClassCapacitor » DeviceClass

This class is similar to DeviceClassCapacitor, but provides an additional terminal (BULK) for the well or substrate the capacitor is embedded in.

The additional terminal is 'W' for the well/substrate terminal.

This class has been introduced in version 0.26.

Public methods

	void	**_assign**	(const DeviceClass other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new DeviceClassCapacitorWit ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.

Public static methods and constants

[static,const]	unsigned long	**TERMINAL_W**	A constant giving the terminal ID for terminal W (well, bulk)

Detailed description

TERMINAL_W

Signature: *[static,const]* unsigned long **TERMINAL_W**

Description: A constant giving the terminal ID for terminal W (well, bulk)

Python specific notes:
The object exposes a readable attribute 'TERMINAL_W'. This is the getter.

_assign

Signature: void **_assign** (const DeviceClassCapacitorWithBulk other)

Description: Assigns another object to self

_create	**Signature**: void **_create** **Description**: Ensures the C++ object is created Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
_destroy	**Signature**: void **_destroy** **Description**: Explicitly destroys the object Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
_destroyed?	**Signature**: *[const]* bool **_destroyed?** **Description**: Returns a value indicating whether the object was already destroyed This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
_dup	**Signature**: *[const]* new DeviceClassCapacitorWithBulk ptr **_dup** **Description**: Creates a copy of self
_is_const_object?	**Signature**: *[const]* bool **_is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference This method returns true, if self is a const reference. In that case, only const methods may be called on self.
_manage	**Signature**: void **_manage** **Description**: Marks the object as managed by the script side. After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required. Usually it's not required to call this method. It has been introduced in version 0.24.
_unmanage	**Signature**: void **_unmanage** **Description**: Marks the object as no longer owned by the script side. Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.

4.147. API reference - Class DeviceClassInductor

Notation used in Ruby API documentation

Module: db

Description: A device class for an inductor.

Class hierarchy: DeviceClassInductor » DeviceClass

This class describes an inductor. Inductors are defined by their combination behavior and the basic parameter 'L' which is the inductance in Henry.

An inductor has two terminals, A and B.

This class has been introduced in version 0.26.

Public methods

	void	**_assign**	(const DeviceClas other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new DeviceClassInductor ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.

Public static methods and constants

[static,const]	unsigned long	**PARAM_L**	A constant giving the parameter ID for parameter L
[static,const]	unsigned long	**TERMINAL_A**	A constant giving the terminal ID for terminal A
[static,const]	unsigned long	**TERMINAL_B**	A constant giving the terminal ID for terminal B

Detailed description

PARAM_L

Signature: *[static,const]* unsigned long **PARAM_L**

Description: A constant giving the parameter ID for parameter L

Python specific notes:

	The object exposes a readable attribute 'PARAM_L'. This is the getter.
TERMINAL_A	**Signature**: *[static,const]* unsigned long **TERMINAL_A** **Description**: A constant giving the terminal ID for terminal A **Python specific notes:** The object exposes a readable attribute 'TERMINAL_A'. This is the getter.
TERMINAL_B	**Signature**: *[static,const]* unsigned long **TERMINAL_B** **Description**: A constant giving the terminal ID for terminal B **Python specific notes:** The object exposes a readable attribute 'TERMINAL_B'. This is the getter.
_assign	**Signature**: void **_assign** (const DeviceClassInductor other) **Description**: Assigns another object to self
_create	**Signature**: void **_create** **Description**: Ensures the C++ object is created Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
_destroy	**Signature**: void **_destroy** **Description**: Explicitly destroys the object Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
_destroyed?	**Signature**: *[const]* bool **_destroyed?** **Description**: Returns a value indicating whether the object was already destroyed This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
_dup	**Signature**: *[const]* new DeviceClassInductor ptr **_dup** **Description**: Creates a copy of self
_is_const_object?	**Signature**: *[const]* bool **_is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference This method returns true, if self is a const reference. In that case, only const methods may be called on self.
_manage	**Signature**: void **_manage** **Description**: Marks the object as managed by the script side. After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

4.148. API reference - Class DeviceClassDiode

Notation used in Ruby API documentation

Module: db

Description: A device class for a diode.

Class hierarchy: DeviceClassDiode » DeviceClass

This class describes a diode. A diode has two terminals, A (anode) and C (cathode). It has two parameters: The diode area in square micrometers (A) and the diode area perimeter in micrometers (P).

Diodes only combine when parallel and in the same direction. In this case, their areas and perimeters are added. This class has been introduced in version 0.26.

Public methods

	void	**_assign**	(const DeviceClas other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new DeviceClassDiode ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.

Public static methods and constants

[static,const]	unsigned long	**PARAM_A**	A constant giving the parameter ID for parameter A
[static,const]	unsigned long	**PARAM_P**	A constant giving the parameter ID for parameter P
[static,const]	unsigned long	**TERMINAL_A**	A constant giving the terminal ID for terminal A
[static,const]	unsigned long	**TERMINAL_C**	A constant giving the terminal ID for terminal C

Detailed description

PARAM_A

Signature: *[static,const]* unsigned long **PARAM_A**

Description: A constant giving the parameter ID for parameter A

Python specific notes:
The object exposes a readable attribute 'PARAM_A'. This is the getter.

PARAM_P

Signature: *[static,const]* unsigned long **PARAM_P**

Description: A constant giving the parameter ID for parameter P

Python specific notes:
The object exposes a readable attribute 'PARAM_P'. This is the getter.

TERMINAL_A

Signature: *[static,const]* unsigned long **TERMINAL_A**

Description: A constant giving the terminal ID for terminal A

Python specific notes:
The object exposes a readable attribute 'TERMINAL_A'. This is the getter.

TERMINAL_C

Signature: *[static,const]* unsigned long **TERMINAL_C**

Description: A constant giving the terminal ID for terminal C

Python specific notes:
The object exposes a readable attribute 'TERMINAL_C'. This is the getter.

_assign

Signature: void **_assign** (const DeviceClassDiode other)

Description: Assigns another object to self

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_dup

Signature: *[const]* new DeviceClassDiode ptr **_dup**

Description: Creates a copy of self

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

4.149. API reference - Class DeviceClassBJT3Transistor

Notation used in Ruby API documentation

Module: db

Description: A device class for a bipolar transistor.

Class hierarchy: DeviceClassBJT3Transistor » DeviceClass

This class describes a bipolar transistor. Bipolar transistors have tree terminals: the collector (C), the base (B) and the emitter (E). Multi-emitter transistors are resolved in individual devices. The parameters are AE, AB and AC for the emitter, base and collector areas in square micrometers and PE, PB and PC for the emitter, base and collector perimeters in micrometers. In addition, the emitter count (NE) is given. The emitter count is 1 always for a transistor extracted initially. Upon combination of devices, the emitter counts are added, thus forming multi-emitter devices.

This class has been introduced in version 0.26.

Public methods

	void	**_assign**	(const DeviceClass other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new DeviceClassBJT3Transis ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.

Public static methods and constants

[static,const]	unsigned long	**PARAM_AB**	A constant giving the parameter ID for parameter AB (base area)
[static,const]	unsigned long	**PARAM_AC**	A constant giving the parameter ID for parameter AC (collector area)
[static,const]	unsigned long	**PARAM_AE**	A constant giving the parameter ID for parameter AE (emitter area)
[static,const]	unsigned long	**PARAM_NE**	A constant giving the parameter ID for parameter NE (emitter count)
[static,const]	unsigned long	**PARAM_PB**	A constant giving the parameter ID for parameter PB (base perimeter)

[static,const]	unsigned long	**PARAM_PC**	A constant giving the parameter ID for parameter PC (collector perimeter)
[static,const]	unsigned long	**PARAM_PE**	A constant giving the parameter ID for parameter PE (emitter perimeter)
[static,const]	unsigned long	**TERMINAL_B**	A constant giving the terminal ID for terminal B (base)
[static,const]	unsigned long	**TERMINAL_C**	A constant giving the terminal ID for terminal C (collector)
[static,const]	unsigned long	**TERMINAL_E**	A constant giving the terminal ID for terminal E (emitter)

Detailed description

PARAM_AB

Signature: *[static,const]* unsigned long **PARAM_AB**

Description: A constant giving the parameter ID for parameter AB (base area)

Python specific notes:
The object exposes a readable attribute 'PARAM_AB'. This is the getter.

PARAM_AC

Signature: *[static,const]* unsigned long **PARAM_AC**

Description: A constant giving the parameter ID for parameter AC (collector area)

Python specific notes:
The object exposes a readable attribute 'PARAM_AC'. This is the getter.

PARAM_AE

Signature: *[static,const]* unsigned long **PARAM_AE**

Description: A constant giving the parameter ID for parameter AE (emitter area)

Python specific notes:
The object exposes a readable attribute 'PARAM_AE'. This is the getter.

PARAM_NE

Signature: *[static,const]* unsigned long **PARAM_NE**

Description: A constant giving the parameter ID for parameter NE (emitter count)

Python specific notes:
The object exposes a readable attribute 'PARAM_NE'. This is the getter.

PARAM_PB

Signature: *[static,const]* unsigned long **PARAM_PB**

Description: A constant giving the parameter ID for parameter PB (base perimeter)

Python specific notes:
The object exposes a readable attribute 'PARAM_PB'. This is the getter.

PARAM_PC

Signature: *[static,const]* unsigned long **PARAM_PC**

Description: A constant giving the parameter ID for parameter PC (collector perimeter)

Python specific notes:
The object exposes a readable attribute 'PARAM_PC'. This is the getter.

PARAM_PE

Signature: *[static,const]* unsigned long **PARAM_PE**

Description: A constant giving the parameter ID for parameter PE (emitter perimeter)

	Python specific notes: The object exposes a readable attribute 'PARAM_PE'. This is the getter.
TERMINAL_B	**Signature**: *[static,const]* unsigned long **TERMINAL_B** **Description**: A constant giving the terminal ID for terminal B (base) **Python specific notes:** The object exposes a readable attribute 'TERMINAL_B'. This is the getter.
TERMINAL_C	**Signature**: *[static,const]* unsigned long **TERMINAL_C** **Description**: A constant giving the terminal ID for terminal C (collector) **Python specific notes:** The object exposes a readable attribute 'TERMINAL_C'. This is the getter.
TERMINAL_E	**Signature**: *[static,const]* unsigned long **TERMINAL_E** **Description**: A constant giving the terminal ID for terminal E (emitter) **Python specific notes:** The object exposes a readable attribute 'TERMINAL_E'. This is the getter.
_assign	**Signature**: void **_assign** (const DeviceClassBJT3Transistor other) **Description**: Assigns another object to self
_create	**Signature**: void **_create** **Description**: Ensures the C++ object is created Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
_destroy	**Signature**: void **_destroy** **Description**: Explicitly destroys the object Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
_destroyed?	**Signature**: *[const]* bool **_destroyed?** **Description**: Returns a value indicating whether the object was already destroyed This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
_dup	**Signature**: *[const]* new DeviceClassBJT3Transistor ptr **_dup** **Description**: Creates a copy of self
_is_const_object?	**Signature**: *[const]* bool **_is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

4.150. API reference - Class DeviceClassBJT4Transistor

Notation used in Ruby API documentation

Module: db

Description: A device class for a 4-terminal bipolar transistor.

Class hierarchy: DeviceClassBJT4Transistor » DeviceClassBJT3Transistor » DeviceClass

This class describes a bipolar transistor with a substrate terminal. A device class for a bipolar transistor without a substrate terminal is DeviceClassBJT3Transistor. The additional terminal is 'S' for the substrate terminal. BJT4 transistors combine in parallel if both substrate terminals are connected to the same net.

This class has been introduced in version 0.26.

Public methods

	void	**_assign**	(const DeviceClass other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new DeviceClassBJT4Transis ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.

Public static methods and constants

[static,const]	unsigned long	**TERMINAL_S**	A constant giving the terminal ID for terminal S

Detailed description

TERMINAL_S

Signature: *[static,const]* unsigned long **TERMINAL_S**

Description: A constant giving the terminal ID for terminal S

Python specific notes:
The object exposes a readable attribute 'TERMINAL_S'. This is the getter.

_assign

Signature: void **_assign** (const DeviceClassBJT4Transistor other)

Description: Assigns another object to self

_create	**Signature**: void **_create** **Description**: Ensures the C++ object is created Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
_destroy	**Signature**: void **_destroy** **Description**: Explicitly destroys the object Explicitly destroys the object on C++ side if it was owned by the script interpreter. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.

4.151. API reference - Class DeviceClassMOS3Transistor

Notation used in Ruby API documentation

Module: db

Description: A device class for a 3-terminal MOS transistor.

Class hierarchy: DeviceClassMOS3Transistor » DeviceClass

This class describes a MOS transistor without a bulk terminal. A device class for a MOS transistor with a bulk terminal is DeviceClassMOS4Transistor. MOS transistors are defined by their combination behavior and the basic parameters.

The parameters are L, W, AS, AD, PS and PD for the gate length and width in micrometers, source and drain area in square micrometers and the source and drain perimeter in micrometers.

The terminals are S, G and D for source, gate and drain.

MOS transistors combine in parallel mode, when both gate lengths are identical and their gates are connected (source and drain can be swapped). In this case, their widths and source and drain areas are added.

This class has been introduced in version 0.26.

Public methods

	void	**_assign**	(const DeviceClassM other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new DeviceClassMOS3Trar ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
[const]	void	**join_split_gates**	(Circuit ptr circuit)	Joins source/drain nets from 'split gate' transistor strings on the given circuit

Public static methods and constants

[static,const]	unsigned long	**PARAM_AD**	A constant giving the parameter ID for parameter AD
[static,const]	unsigned long	**PARAM_AS**	A constant giving the parameter ID for parameter AS
[static,const]	unsigned long	**PARAM_L**	A constant giving the parameter ID for parameter L

[static,const]	unsigned long	**PARAM_PD**	A constant giving the parameter ID for parameter PD
[static,const]	unsigned long	**PARAM_PS**	A constant giving the parameter ID for parameter PS
[static,const]	unsigned long	**PARAM_W**	A constant giving the parameter ID for parameter W
[static,const]	unsigned long	**TERMINAL_D**	A constant giving the terminal ID for terminal D
[static,const]	unsigned long	**TERMINAL_G**	A constant giving the terminal ID for terminal G
[static,const]	unsigned long	**TERMINAL_S**	A constant giving the terminal ID for terminal S

Detailed description

PARAM_AD

Signature: *[static,const]* unsigned long **PARAM_AD**

Description: A constant giving the parameter ID for parameter AD

Python specific notes:
The object exposes a readable attribute 'PARAM_AD'. This is the getter.

PARAM_AS

Signature: *[static,const]* unsigned long **PARAM_AS**

Description: A constant giving the parameter ID for parameter AS

Python specific notes:
The object exposes a readable attribute 'PARAM_AS'. This is the getter.

PARAM_L

Signature: *[static,const]* unsigned long **PARAM_L**

Description: A constant giving the parameter ID for parameter L

Python specific notes:
The object exposes a readable attribute 'PARAM_L'. This is the getter.

PARAM_PD

Signature: *[static,const]* unsigned long **PARAM_PD**

Description: A constant giving the parameter ID for parameter PD

Python specific notes:
The object exposes a readable attribute 'PARAM_PD'. This is the getter.

PARAM_PS

Signature: *[static,const]* unsigned long **PARAM_PS**

Description: A constant giving the parameter ID for parameter PS

Python specific notes:
The object exposes a readable attribute 'PARAM_PS'. This is the getter.

PARAM_W

Signature: *[static,const]* unsigned long **PARAM_W**

Description: A constant giving the parameter ID for parameter W

Python specific notes:
The object exposes a readable attribute 'PARAM_W'. This is the getter.

TERMINAL_D

Signature: *[static,const]* unsigned long **TERMINAL_D**

Description: A constant giving the terminal ID for terminal D

Python specific notes:
The object exposes a readable attribute 'TERMINAL_D'. This is the getter.

TERMINAL_G

Signature: *[static,const]* unsigned long **TERMINAL_G**

Description: A constant giving the terminal ID for terminal G

Python specific notes:
The object exposes a readable attribute 'TERMINAL_G'. This is the getter.

TERMINAL_S

Signature: *[static,const]* unsigned long **TERMINAL_S**

Description: A constant giving the terminal ID for terminal S

Python specific notes:
The object exposes a readable attribute 'TERMINAL_S'. This is the getter.

_assign

Signature: void **_assign** (const DeviceClassMOS3Transistor other)

Description: Assigns another object to self

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_dup

Signature: *[const]* new DeviceClassMOS3Transistor ptr **_dup**

Description: Creates a copy of self

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

	Usually it's not required to call this method. It has been introduced in version 0.24.
_unmanage	**Signature**: void **_unmanage** **Description**: Marks the object as no longer owned by the script side. Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.
join_split_gates	**Signature**: *[const]* void **join_split_gates** (Circuit ptr circuit) **Description**: Joins source/drain nets from 'split gate' transistor strings on the given circuit This method has been introduced in version 0.27.9

4.152. API reference - Class DeviceClassMOS4Transistor

Notation used in Ruby API documentation

Module: db

Description: A device class for a 4-terminal MOS transistor.

Class hierarchy: DeviceClassMOS4Transistor » DeviceClassMOS3Transistor » DeviceClass

This class describes a MOS transistor with a bulk terminal. A device class for a MOS transistor without a bulk terminal is DeviceClassMOS3Transistor. MOS transistors are defined by their combination behavior and the basic parameters.

The additional terminal is 'B' for the bulk terminal. MOS4 transistors combine in parallel if both bulk terminals are connected to the same net.

This class has been introduced in version 0.26.

Public methods

	void	**_assign**	(const DeviceClass other)	Assigns another object to self
	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	new DeviceClassMOS4Trans ptr	**_dup**		Creates a copy of self
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.

Public static methods and constants

[static,const]	unsigned long	**TERMINAL_B**	A constant giving the terminal ID for terminal B

Detailed description

TERMINAL_B

Signature: *[static,const]* unsigned long **TERMINAL_B**

Description: A constant giving the terminal ID for terminal B

Python specific notes:
The object exposes a readable attribute 'TERMINAL_B'. This is the getter.

_assign

Signature: void **_assign** (const DeviceClassMOS4Transistor other)

Description: Assigns another object to self

_create	**Signature**: void **_create** **Description**: Ensures the C++ object is created Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.
_destroy	**Signature**: void **_destroy** **Description**: Explicitly destroys the object Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
_destroyed?	**Signature**: *[const]* bool **_destroyed?** **Description**: Returns a value indicating whether the object was already destroyed This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
_dup	**Signature**: *[const]* new DeviceClassMOS4Transistor ptr **_dup** **Description**: Creates a copy of self
_is_const_object?	**Signature**: *[const]* bool **_is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference This method returns true, if self is a const reference. In that case, only const methods may be called on self.
_manage	**Signature**: void **_manage** **Description**: Marks the object as managed by the script side. After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required. Usually it's not required to call this method. It has been introduced in version 0.24.
_unmanage	**Signature**: void **_unmanage** **Description**: Marks the object as no longer owned by the script side. Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur. Usually it's not required to call this method. It has been introduced in version 0.24.

4.153. API reference - Class DeviceClassFactory

Notation used in Ruby API documentation

Module: db

Description: A factory for creating specific device classes for the standard device extractors

Use a reimplementation of this class to provide a device class generator for built-in device extractors such as DeviceExtractorMOS3Transistor. The constructor of this extractor has a 'factory' parameter which takes an object of DeviceClassFactory type.

If such an object is provided, this factory is used to create the actual device class. The following code shows an example:

```
class MyClass < RBA::DeviceClassMOS3Transistor
  ... overrides some methods ...
end

class MyFactory < RBA::DeviceClassFactory
  def create_class
    MyClass.new
  end
end

extractor = RBA::DeviceExtractorMOS3Transistor::new("NMOS", false, MyFactory.new)
```

When using a factory with a device extractor, make sure it creates a corresponding device class, e.g. for the DeviceExtractorMOS3Transistor extractor create a device class derived from DeviceClassMOS3Transistor.

This class has been introduced in version 0.27.3.

Public constructors

new DeviceClassFactory ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const DeviceCla other)	Assigns another object to self
[virtual,const]	new DeviceClass ptr	**create_class**		Creates the DeviceClass object

[const]	new DeviceClassFactory ptr	**dup**	Creates a copy of self

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const DeviceClassFactory other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

create_class

Signature: *[virtual,const]* new DeviceClass ptr **create_class**

Description: Creates the DeviceClass object

Reimplement this method to create the desired device class.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new DeviceClassFactory ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

new

Signature: *[static]* new DeviceClassFactory ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

4.154. API reference - Class NetlistDeviceExtractorLayerDefinition

Notation used in Ruby API documentation

Module: db

Description: Describes a layer used in the device extraction

This read-only structure is used to describe a layer in the device extraction. Every device has specific layers used in the device extraction process. Layer definitions can be retrieved using NetlistDeviceExtractor#each_layer.

This class has been introduced in version 0.26.

Public constructors

new NetlistDeviceExtractorLayerDefinition ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const NetlistDevi other)	Assigns another object to self
[const]	string	**description**		Gets the description of the layer.
[const]	new NetlistDeviceExtractorLay ptr	**dup**		Creates a copy of self
[const]	unsigned long	**fallback_index**		Gets the index of the fallback layer.
[const]	unsigned long	**index**		Gets the index of the layer.
[const]	string	**name**		Gets the name of the layer.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead

[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const NetlistDeviceExtractorLayerDefinition other)

Description: Assigns another object to self

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

description

Signature: *[const]* string **description**

Description: Gets the description of the layer.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

dup

Signature: *[const]* new NetlistDeviceExtractorLayerDefinition ptr **dup**

Description: Creates a copy of self

Python specific notes:
This method also implements '__copy__' and '__deepcopy__'.

fallback_index

Signature: *[const]* unsigned long **fallback_index**

Description: Gets the index of the fallback layer.

This is the index of the layer to be used when this layer isn't specified for input or (more important) output.

index

Signature: *[const]* unsigned long **index**

Description: Gets the index of the layer.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

name

Signature: *[const]* string **name**

Description: Gets the name of the layer.

new

Signature: *[static]* new NetlistDeviceExtractorLayerDefinition ptr **new**

Description: Creates a new object of this class

Python specific notes:
This method is the default initializer of the object.

4.155. API reference - Class DeviceExtractorBase

Notation used in Ruby API documentation

Module: db

Description: The base class for all device extractors.

This is an abstract base class for device extractors. See GenericDeviceExtractor for a generic class which you can reimplement to supply your own customized device extractor. In many cases using one of the preconfigured specific device extractors may be useful already and it's not required to implement a custom one. For an example about a preconfigured device extractor see DeviceExtractorMOS3Transistor.

This class cannot and should not be instantiated explicitly. Use one of the subclasses instead.

This class has been introduced in version 0.26.

Public constructors

new DeviceExtractorBase ptr	**new**	Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	DeviceClass ptr	**device_class**		Gets the device class used during extraction
[const,iter]	NetlistDeviceExtractorLayerDefinition	**each_layer_definition**		Iterates over all layer definitions.
[iter]	LogEntryData	**each_log_entry**		Iterates over all log entries collected in the device extractor.Starting with version 0.28.13, the preferred name of the method is 'each_log_entry' as log entries have been generalized to become warnings too.
[const]	string	**name**		Gets the name of the device extractor and the device class.
	void	**name=**	(string name)	Sets the name of the device extractor and the device class.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead

[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[iter]	LogEntryData	**each_error**	Use of this method is deprecated. Use each_log_entry instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

destroyed?

Signature: *[const]* bool **destroyed?**

Description: Returns a value indicating whether the object was already destroyed

Use of this method is deprecated. Use _destroyed? instead

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

device_class

Signature: DeviceClass ptr **device_class**

Description: Gets the device class used during extraction

The attribute will hold the actual device class used in the device extraction. It is valid only after 'extract_devices'.

This method has been added in version 0.27.3.

each_error

Signature: *[iter]* LogEntryData **each_error**

Description: Iterates over all log entries collected in the device extractor.Starting with version 0.28.13, the preferred name of the method is 'each_log_entry' as log entries have been generalized to become warnings too.

Use of this method is deprecated. Use each_log_entry instead

each_layer_definition

Signature: *[const,iter]* NetlistDeviceExtractorLayerDefinition **each_layer_definition**

Description: Iterates over all layer definitions.

each_log_entry

Signature: *[iter]* LogEntryData **each_log_entry**

Description: Iterates over all log entries collected in the device extractor.Starting with version 0.28.13, the preferred name of the method is 'each_log_entry' as log entries have been generalized to become warnings too.

is_const_object?

Signature: *[const]* bool **is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

Use of this method is deprecated. Use _is_const_object? instead

	This method returns true, if self is a const reference. In that case, only const methods may be called on self.
name	**Signature**: *[const]* string **name** **Description**: Gets the name of the device extractor and the device class. **Python specific notes:** The object exposes a readable attribute 'name'. This is the getter.
name=	**Signature**: void **name=** (string name) **Description**: Sets the name of the device extractor and the device class. **Python specific notes:** The object exposes a writable attribute 'name'. This is the setter.
new	**Signature**: *[static]* new DeviceExtractorBase ptr **new** **Description**: Creates a new object of this class **Python specific notes:** This method is the default initializer of the object.

4.156. API reference - Class GenericDeviceExtractor

Notation used in Ruby API documentation

Module: db

Description: The basic class for implementing custom device extractors.

Class hierarchy: GenericDeviceExtractor » DeviceExtractorBase

This class serves as a base class for implementing customized device extractors. This class does not provide any extraction functionality, so you have to implement every detail.

Device extraction requires a few definitions. The definitions are made in the reimplementation of the setup method. Required definitions to be made are:

- The name of the extractor. This will also be the name of the device class produced by the extractor. The name is set using name=.
- The device class of the devices to produce. The device class is registered using register_device_class.
- The layers used for the device extraction. These are input layers for the extraction as well as output layers for defining the terminals. Terminals are the points at which the nets connect to the devices. Layers are defined using define_layer. Initially, layers are abstract definitions with a name and a description. Concrete layers will be given when defining the connectivity.

When the device extraction is started, the device extraction algorithm will first ask the device extractor for the 'connectivity'. This is not a connectivity in a sense of electrical connections. The connectivity defines are logical compound that makes up the device. 'Connected' shapes are collected and presented to the device extractor. The connectivity is obtained by calling get_connectivity. This method must be implemented to produce the connectivity.

Finally, the individual devices need to be extracted. Each cluster of connected shapes is presented to the device extractor. A cluster may include more than one device. It's the device extractor's responsibility to extract the devices from this cluster and deliver the devices through create_device. In addition, terminals have to be defined, so the net extractor can connect to the devices. Terminal definitions are made through define_terminal. The device extraction is implemented in the extract_devices method.

If errors occur during device extraction, the error method may be used to issue such errors. Errors reported this way are kept in the error log.

This class has been introduced in version 0.26.

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	Device ptr	**create_device**		Creates a device.
[const]	double	**dbu**		Gets the database unit
	NetlistDeviceExtrac	**define_layer**	(string name, string description)	Defines a layer.

	NetlistDeviceExtractorLayerDefinition	**define_layer**	(string name, unsigned long fallback, string description)	Defines a layer with a fallback layer.
	void	**define_terminal**	(Device ptr device, unsigned long terminal_id, unsigned long layer_index, const Polygon shape)	Defines a device terminal.
	void	**define_terminal**	(Device ptr device, unsigned long terminal_id, unsigned long layer_index, const Box shape)	Defines a device terminal.
	void	**define_terminal**	(Device ptr device, unsigned long terminal_id, unsigned long layer_index, const Point point)	Defines a device terminal.
	void	**define_terminal**	(Device ptr device, string terminal_name, string layer_name, const Polygon shape)	Defines a device terminal using names for terminal and layer.
	void	**define_terminal**	(Device ptr device, string terminal_name, string layer_name, const Box shape)	Defines a device terminal using names for terminal and layer.
	void	**define_terminal**	(Device ptr device, string terminal_name, string layer_name, const Point point)	Defines a device terminal using names for terminal and layer.
	void	**error**	(string message)	Issues an error with the given message
	void	**error**	(string message, const DPolygon geometry)	Issues an error with the given message and micrometer-units polygon geometry
	void	**error**	(string message, const Polygon geometry)	Issues an error with the given message and database-unit polygon geometry
	void	**error**	(string category_name, string category_description, string message)	Issues an error with the given category name and description, message
	void	**error**	(string category_name, string category_description, string message, const DPolygon geometry)	Issues an error with the given category name and description, message and micrometer-units polygon geometry
	void	**error**	(string category_name, string category_description, string message, const Polygon geometry)	Issues an error with the given category name and description, message and database-unit polygon geometry
[virtual]	void	**extract_devices**	(Region[] layer_geometry)	Extracts the devices from the given shape cluster.

[virtual,const]	Connectivity	**get_connectivity**	(const Layout layout, unsigned int[] layers)	Gets the connectivity object used to extract the device geometry.
	void	**register_device_cla**	(DeviceClass ptr device_class)	Registers a device class.
[const]	double	**sdbu**		Gets the scaled database unit
[virtual]	void	**setup**		Sets up the extractor.
	void	**warn**	(string message)	Issues a warning with the given message
	void	**warn**	(string message, const DPolygon geometry)	Issues a warning with the given message and micrometer-units polygon geometry
	void	**warn**	(string message, const Polygon geometry)	Issues a warning with the given message and database-unit polygon geometry
	void	**warn**	(string category_name, string category_description, string message)	Issues a warning with the given category name and description, message
	void	**warn**	(string category_name, string category_description, string message, const DPolygon geometry)	Issues a warning with the given category name and description, message and micrometer-units polygon geometry
	void	**warn**	(string category_name, string category_description, string message, const Polygon geometry)	Issues a warning with the given category name and description, message and database-unit polygon geometry

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

create_device

Signature: Device ptr **create_device**

Description: Creates a device.

The device object returned can be configured by the caller, e.g. set parameters. It will be owned by the netlist and must not be deleted by the caller.

dbu

Signature: *[const]* double **dbu**

Description: Gets the database unit

define_layer

Signature: NetlistDeviceExtractorLayerDefinition **define_layer** (string name, string description)

Description: Defines a layer.

Returns: The layer descriptor object created for this layer (use 'index' to get the layer's index)

Each call will define one more layer for the device extraction. This method shall be used inside the implementation of setup to define the device layers. The actual geometries are later available to extract_devices in the order the layers are defined.

define_opt_layer

Signature: NetlistDeviceExtractorLayerDefinition **define_opt_layer** (string name, unsigned long fallback, string description)

Description: Defines a layer with a fallback layer.

Returns: The layer descriptor object created for this layer (use 'index' to get the layer's index)

As define_layer, this method allows specification of device extraction layer. In addition to define_layout, it features a fallback layer. If in the device extraction statement, the primary layer is not given, the fallback layer will be used. Hence, this layer is optional. The fallback layer is given by its index and must be defined before the layer using the fallback layer is defined. For the index, 0 is the first layer defined, 1 the second and so forth.

define_terminal

(1) Signature: void **define_terminal** (Device ptr device, unsigned long terminal_id, unsigned long layer_index, const Polygon shape)

Description: Defines a device terminal.

This method will define a terminal to the given device and the given terminal ID. The terminal will be placed on the layer given by "layer_index". The layer index is the index of the layer during layer definition. The first layer is 0, the second layer 1 etc.

This version produces a terminal with a shape given by the polygon. Note that the polygon is specified in database units.

(2) Signature: void **define_terminal** (Device ptr device, unsigned long terminal_id, unsigned long layer_index, const Box shape)

Description: Defines a device terminal.

This method will define a terminal to the given device and the given terminal ID. The terminal will be placed on the layer given by "layer_index". The layer index is the index of the layer during layer definition. The first layer is 0, the second layer 1 etc.

This version produces a terminal with a shape given by the box. Note that the box is specified in database units.

(3) Signature: void **define_terminal** (Device ptr device, unsigned long terminal_id, unsigned long layer_index, const Point point)

Description: Defines a device terminal.

This method will define a terminal to the given device and the given terminal ID. The terminal will be placed on the layer given by "layer_index". The layer index is the index of the layer during layer definition. The first layer is 0, the second layer 1 etc.

This version produces a point-like terminal. Note that the point is specified in database units.

(4) Signature: void **define_terminal** (Device ptr device, string terminal_name, string layer_name, const Polygon shape)

Description: Defines a device terminal using names for terminal and layer.

This convenience version of the ID-based define_terminal methods allows using names for terminal and layer. It has been introduced in version 0.28.

(5) Signature: void **define_terminal** (Device ptr device, string terminal_name, string layer_name, const Box shape)

Description: Defines a device terminal using names for terminal and layer.

This convenience version of the ID-based define_terminal methods allows using names for terminal and layer. It has been introduced in version 0.28.

(6) Signature: void **define_terminal** (Device ptr device, string terminal_name, string layer_name, const Point point)

Description: Defines a device terminal using names for terminal and layer.

This convenience version of the ID-based define_terminal methods allows using names for terminal and layer. It has been introduced in version 0.28.

error

(1) Signature: void **error** (string message)

Description: Issues an error with the given message

(2) Signature: void **error** (string message, const DPolygon geometry)

Description: Issues an error with the given message and micrometer-units polygon geometry

(3) Signature: void **error** (string message, const Polygon geometry)

Description: Issues an error with the given message and database-unit polygon geometry

(4) Signature: void **error** (string category_name, string category_description, string message)

Description: Issues an error with the given category name and description, message

(5) Signature: void **error** (string category_name, string category_description, string message, const DPolygon geometry)

Description: Issues an error with the given category name and description, message and micrometer-units polygon geometry

(6) Signature: void **error** (string category_name, string category_description, string message, const Polygon geometry)

Description: Issues an error with the given category name and description, message and database-unit polygon geometry

extract_devices

Signature: *[virtual]* void **extract_devices** (Region[] layer_geometry)

Description: Extracts the devices from the given shape cluster.

The shape cluster is a set of geometries belonging together in terms of the connectivity defined by "get_connectivity". The cluster might cover multiple devices, so the implementation needs to consider this case. The geometries are already merged.

The implementation of this method shall use "create_device" to create new devices based on the geometry found. It shall use "define_terminal" to define terminals by which the nets extracted in the network extraction step connect to the new devices.

get_connectivity

Signature: *[virtual,const]* Connectivity **get_connectivity** (const Layout layout, unsigned int[] layers)

Description: Gets the connectivity object used to extract the device geometry.

This method shall raise an error, if the input layer are not properly defined (e.g. too few etc.)

This is not a connectivity definition in the electrical sense, but defines the cluster of shapes which generates a specific device. In this case, 'connectivity' means 'definition of shapes that need to touch to form the device'.

The 'layers' argument specifies the actual layer layouts for the logical device layers (see define_layer). The list of layers corresponds to the number of layers defined. Use the layer indexes from this list to build the connectivity with Connectivity#connect. Note, that in order to capture a connected cluster of shapes on the same layer you'll need to include a self-connection like 'connectivity.connect(layers[0], layers[0])'.

register_device_class

Signature: void **register_device_class** (DeviceClass ptr device_class)

Description: Registers a device class.

The device class object will become owned by the netlist and must not be deleted by the caller. The name of the device class will be changed to the name given to the device extractor. This method shall be used inside the implementation of setup to register the device classes.

sdbu

Signature: *[const]* double **sdbu**

Description: Gets the scaled database unit

Use this unit to compute device properties. It is the database unit multiplied with the device scaling factor.

setup

Signature: *[virtual]* void **setup**

Description: Sets up the extractor.

This method is supposed to set up the device extractor. This involves three basic steps: defining the name, the device class and setting up the device layers.

Use name= to give the extractor and its device class a name. Use register_device_class to register the device class you need. Defined the layers by calling define_layer once or several times.

warn

(1) Signature: void **warn** (string message)

Description: Issues a warning with the given message

Warnings have been introduced in version 0.28.13.

(2) Signature: void **warn** (string message, const DPolygon geometry)

Description: Issues a warning with the given message and micrometer-units polygon geometry

Warnings have been introduced in version 0.28.13.

(3) Signature: void **warn** (string message, const Polygon geometry)

Description: Issues a warning with the given message and database-unit polygon geometry

Warnings have been introduced in version 0.28.13.

(4) Signature: void **warn** (string category_name, string category_description, string message)

Description: Issues a warning with the given category name and description, message

Warnings have been introduced in version 0.28.13.

(5) Signature: void **warn** (string category_name, string category_description, string message, const DPolygon geometry)

Description: Issues a warning with the given category name and description, message and micrometer-units polygon geometry

Warnings have been introduced in version 0.28.13.

(6) Signature: void **warn** (string category_name, string category_description, string message, const Polygon geometry)

Description: Issues a warning with the given category name and description, message and database-unit polygon geometry

Warnings have been introduced in version 0.28.13.

4.157. API reference - Class DeviceExtractorMOS3Transistor

Notation used in Ruby API documentation

Module: db

Description: A device extractor for a three-terminal MOS transistor

Class hierarchy: DeviceExtractorMOS3Transistor » DeviceExtractorBase

This class supplies the generic extractor for a MOS device. The device is defined by two basic input layers: the diffusion area (source and drain) and the gate area. It requires a third layer (poly) to put the gate terminals on. The separation between poly and allows separating the device recognition layer (gate) from the conductive layer.

The device class produced by this extractor is DeviceClassMOS3Transistor.

The extractor delivers six parameters:

- 'L' - the gate length in micrometer units
- 'W' - the gate width in micrometer units
- 'AS' and 'AD' - the source and drain region areas in square micrometers
- 'PS' and 'PD' - the source and drain region perimeters in micrometer units

The device layer names are:

- In strict mode: 'S' (source), 'D' (drain) and 'G' (gate).
- In non-strict mode: 'SD' (source and drain) and 'G' (gate).

The terminals are output on these layers:

- 'tS' - source. Default output is 'S' (strict mode) or 'SD' (otherwise).
- 'tD' - drain. Default output is 'D' (strict mode) or 'SD' (otherwise).
- 'tG' - gate. Default output is 'G'.

The source/drain (diffusion) area is distributed on the number of gates connecting to the particular source or drain area.

This class is a closed one and methods cannot be reimplemented. To reimplement specific methods, see DeviceExtractor.

This class has been introduced in version 0.26.

Public constructors

new DeviceExtractorMOS3Transistor ptr	**new**	(string name, bool strict = false, DeviceClassFactory ptr factory = none)	Creates a new device extractor with the given name.

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed

[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference
	void	**_manage**	Marks the object as managed by the script side.
	void	**_unmanage**	Marks the object as no longer owned by the script side.
[const]	bool	**strict?**	Returns a value indicating whether extraction happens in strict mode.

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

new

Signature: *[static]* new DeviceExtractorMOS3Transistor ptr **new** (string name, bool strict = false, DeviceClassFactory ptr factory = none)

Description: Creates a new device extractor with the given name.

If strict is true, the MOS device extraction will happen in strict mode. That is, source and drain are not interchangeable.

For the 'factory' parameter see DeviceClassFactory. It has been added in version 0.27.3.

Python specific notes:
This method is the default initializer of the object.

strict?

Signature: *[const]* bool **strict?**

Description: Returns a value indicating whether extraction happens in strict mode.

4.158. API reference - Class DeviceExtractorMOS4Transistor

Notation used in Ruby API documentation

Module: db

Description: A device extractor for a four-terminal MOS transistor

Class hierarchy: DeviceExtractorMOS4Transistor » DeviceExtractorBase

This class supplies the generic extractor for a MOS device. It is based on the DeviceExtractorMOS3Transistor class with the extension of a bulk terminal and corresponding bulk terminal output (annotation) layer.

The parameters of a MOS4 device are the same than for MOS3 devices. For the device layers the bulk layer is added.

- 'B' (bulk) - currently this layer is not used and can be empty.

The bulk terminals are output on this layer:

- 'tB' - bulk terminal (a copy of the gate shape). Default output is 'B'.

The bulk terminal layer can be empty. In this case, it needs to be connected to a global net to establish the net connection.

The device class produced by this extractor is DeviceClassMOS4Transistor.

This class is a closed one and methods cannot be reimplemented. To reimplement specific methods, see DeviceExtractor.

This class has been introduced in version 0.26.

Public constructors

new DeviceExtractorMOS4Transistor ptr	**new**	(string name, bool strict = false, DeviceClassFactory ptr factory = none)	Creates a new device extractor with the given name

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference
	void	**_manage**	Marks the object as managed by the script side.
	void	**_unmanage**	Marks the object as no longer owned by the script side.

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

new

Signature: *[static]* new DeviceExtractorMOS4Transistor ptr **new** (string name, bool strict = false, DeviceClassFactory ptr factory = none)

Description: Creates a new device extractor with the given name

For the 'factory' parameter see DeviceClassFactory. It has been added in version 0.27.3.

Python specific notes:
This method is the default initializer of the object.

4.159. API reference - Class DeviceExtractorResistor

Notation used in Ruby API documentation

Module: db

Description: A device extractor for a two-terminal resistor

Class hierarchy: DeviceExtractorResistor » DeviceExtractorBase

This class supplies the generic extractor for a resistor device. The device is defined by two geometry layers: the resistor 'wire' and two contacts per wire. The contacts should be attached to the ends of the wire. The wire length and width is computed from the edge lengths between the contacts and along the contacts respectively.

This simple computation is precise only when the resistor shape is a rectangle.

Using the given sheet resistance, the resistance value is computed by 'R = L / W * sheet_rho'.

The device class produced by this extractor is DeviceClassResistor. The extractor produces three parameters:

- 'R' - the resistance in Ohm
- 'A' - the resistor's area in square micrometer units
- 'P' - the resistor's perimeter in micrometer units

The device layer names are:

- 'R' - resistor path. This is the geometry that defines the resistor's current path.
- 'C' - contacts. These areas form the contact regions at the ends of the resistor path.

The terminals are output on these layers:

- 'tA', 'tB' - the two terminals of the resistor.

This class is a closed one and methods cannot be reimplemented. To reimplement specific methods, see DeviceExtractor.

This class has been introduced in version 0.26.

Public constructors

new DeviceExtractorResistor ptr	**new**	(string name, double sheet_rho, DeviceClassFactory ptr factory = none)	Creates a new device extractor with the given name

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference
	void	**_manage**	Marks the object as managed by the script side.
	void	**_unmanage**	Marks the object as no longer owned by the script side.

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

new

Signature: *[static]* new DeviceExtractorResistor ptr **new** (string name, double sheet_rho, DeviceClassFactory ptr factory = none)

Description: Creates a new device extractor with the given name

For the 'factory' parameter see DeviceClassFactory. It has been added in version 0.27.3.

Python specific notes:

This method is the default initializer of the object.

4.160. API reference - Class DeviceExtractorResistorWithBulk

Notation used in Ruby API documentation

Module: db

Description: A device extractor for a resistor with a bulk terminal

Class hierarchy: DeviceExtractorResistorWithBulk » DeviceExtractorBase

This class supplies the generic extractor for a resistor device including a bulk terminal. The device is defined the same way than devices are defined for DeviceExtractorResistor.

The device class produced by this extractor is DeviceClassResistorWithBulk. The extractor produces three parameters:

- 'R' - the resistance in Ohm
- 'A' - the resistor's area in square micrometer units
- 'P' - the resistor's perimeter in micrometer units

The device layer names are:

- 'R' - resistor path. This is the geometry that defines the resistor's current path.
- 'C' - contacts. These areas form the contact regions at the ends of the resistor path.
- 'W' - well, bulk. Currently this layer is ignored for the extraction and can be empty.

The terminals are output on these layers:

- 'tA', 'tB' - the two terminals of the resistor.
- 'tW' - the bulk terminal (copy of the resistor area).

The bulk terminal layer can be an empty layer representing the substrate. In this case, it needs to be connected globally.

This class is a closed one and methods cannot be reimplemented. To reimplement specific methods, see DeviceExtractor.

This class has been introduced in version 0.26.

Public constructors

new DeviceExtractorResistorWithBulk ptr	**new**	(string name, double sheet_rho, DeviceClassFactory ptr factory = none)	Creates a new device extractor with the given name

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference
	void	**_manage**	Marks the object as managed by the script side.
	void	**_unmanage**	Marks the object as no longer owned by the script side.

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

new

Signature: *[static]* new DeviceExtractorResistorWithBulk ptr **new** (string name, double sheet_rho, DeviceClassFactory ptr factory = none)

Description: Creates a new device extractor with the given name

For the 'factory' parameter see DeviceClassFactory. It has been added in version 0.27.3.

Python specific notes:

This method is the default initializer of the object.

4.161. API reference - Class DeviceExtractorCapacitor

Notation used in Ruby API documentation

Module: db

Description: A device extractor for a two-terminal capacitor

Class hierarchy: DeviceExtractorCapacitor » DeviceExtractorBase

This class supplies the generic extractor for a capacitor device. The device is defined by two geometry layers forming the 'plates' of the capacitor. The capacitance is computed from the overlapping area of the plates using 'C = A * area_cap' (area_cap is the capacitance per square micrometer area).

Although 'area_cap' can be given in any unit, Farad should be preferred as this is the convention used for output into a netlist.

The device class produced by this extractor is DeviceClassCapacitor. The extractor produces three parameters:

- 'C' - the capacitance
- 'A' - the capacitor's area in square micrometer units
- 'P' - the capacitor's perimeter in micrometer units

The device layer names are:

- 'P1', 'P2' - the two plates.

The terminals are output on these layers:

- 'tA', 'tB' - the two terminals. Defaults to 'P1' and 'P2'.

This class is a closed one and methods cannot be reimplemented. To reimplement specific methods, see DeviceExtractor.

This class has been introduced in version 0.26.

Public constructors

new DeviceExtractorCapacitor ptr	**new**	(string name, double area_cap, DeviceClassFactory ptr factory = none)	Creates a new device extractor with the given name

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference
	void	**_manage**	Marks the object as managed by the script side.
	void	**_unmanage**	Marks the object as no longer owned by the script side.

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

new

Signature: *[static]* new DeviceExtractorCapacitor ptr **new** (string name, double area_cap, DeviceClassFactory ptr factory = none)

Description: Creates a new device extractor with the given name

For the 'factory' parameter see DeviceClassFactory. It has been added in version 0.27.3.

Python specific notes:

This method is the default initializer of the object.

4.162. API reference - Class DeviceExtractorCapacitorWithBulk

Notation used in Ruby API documentation

Module: db

Description: A device extractor for a capacitor with a bulk terminal

Class hierarchy: DeviceExtractorCapacitorWithBulk » DeviceExtractorBase

This class supplies the generic extractor for a capacitor device including a bulk terminal. The device is defined the same way than devices are defined for DeviceExtractorCapacitor.

The device class produced by this extractor is DeviceClassCapacitorWithBulk. The extractor produces three parameters:

- 'C' - the capacitance
- 'A' - the capacitor's area in square micrometer units
- 'P' - the capacitor's perimeter in micrometer units

The device layer names are:

- 'P1', 'P2' - the two plates.
- 'W' - well, bulk. Currently this layer is ignored for the extraction and can be empty.

The terminals are output on these layers:

- 'tA', 'tB' - the two terminals. Defaults to 'P1' and 'P2'.
- 'tW' - the bulk terminal (copy of the resistor area).

The bulk terminal layer can be an empty layer representing the substrate. In this case, it needs to be connected globally.

This class is a closed one and methods cannot be reimplemented. To reimplement specific methods, see DeviceExtractor.

This class has been introduced in version 0.26.

Public constructors

new DeviceExtractorCapacitorWithBulk ptr	**new**	(string name, double sheet_rho, DeviceClassFactory ptr factory = none)	Creates a new device extractor with the given name

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference
	void	**_manage**	Marks the object as managed by the script side.
	void	**_unmanage**	Marks the object as no longer owned by the script side.

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

new

Signature: *[static]* new DeviceExtractorCapacitorWithBulk ptr **new** (string name, double sheet_rho, DeviceClassFactory ptr factory = none)

Description: Creates a new device extractor with the given name

For the 'factory' parameter see DeviceClassFactory. It has been added in version 0.27.3.

Python specific notes:

This method is the default initializer of the object.

4.163. API reference - Class DeviceExtractorBJT3Transistor

Notation used in Ruby API documentation

Module: db

Description: A device extractor for a bipolar transistor (BJT)

Class hierarchy: DeviceExtractorBJT3Transistor » DeviceExtractorBase

This class supplies the generic extractor for a bipolar transistor device.

Extraction of vertical and lateral transistors is supported through a generic geometry model: The basic area is the base area. A marker shape must be provided for this area. The emitter of the transistor is defined by emitter layer shapes inside the base area. Multiple emitter shapes can be present. In this case, multiple transistor devices sharing the same base and collector are generated. Finally, a collector layer can be given. If non-empty, the parts inside the base region will define the collector terminals. If empty, the collector is formed by the substrate. In this case, the base region will be output to the 'tC' terminal output layer. This layer then needs to be connected to a global net to form the net connection.

The device class produced by this extractor is DeviceClassBJT3Transistor. The extractor delivers these parameters:

- 'AE', 'AB' and 'AC' - the emitter, base and collector areas in square micrometer units
- 'PE', 'PB' and 'PC' - the emitter, base and collector perimeters in micrometer units
- 'NE' - emitter count (initially 1 but increases when devices are combined)

The device layer names are:

- 'E' - emitter.
- 'B' - base.
- 'C' - collector.

The terminals are output on these layers:

- 'tE' - emitter. Default output is 'E'.
- 'tB' - base. Default output is 'B'.
- 'tC' - collector. Default output is 'C'.

This class is a closed one and methods cannot be reimplemented. To reimplement specific methods, see DeviceExtractor.

This class has been introduced in version 0.26.

Public constructors

new DeviceExtractorBJT3Transistor ptr	**new**	(string name, DeviceClassFactory ptr factory = none)	Creates a new device extractor with the given name

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed

[const]	bool	_is_const_object?	Returns a value indicating whether the reference is a const reference
	void	_manage	Marks the object as managed by the script side.
	void	_unmanage	Marks the object as no longer owned by the script side.

Detailed description

_create

Signature: void _**create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void _**destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool _**destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool _**is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void _**manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void _**unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

new

Signature: *[static]* new DeviceExtractorBJT3Transistor ptr **new** (string name, DeviceClassFactory ptr factory = none)

Description: Creates a new device extractor with the given name

For the 'factory' parameter see DeviceClassFactory. It has been added in version 0.27.3.

Python specific notes:
This method is the default initializer of the object.

4.164. API reference - Class DeviceExtractorBJT4Transistor

Notation used in Ruby API documentation

Module: db

Description: A device extractor for a four-terminal bipolar transistor (BJT)

Class hierarchy: DeviceExtractorBJT4Transistor » DeviceExtractorBJT3Transistor » DeviceExtractorBase

This class supplies the generic extractor for a bipolar transistor device. It is based on the DeviceExtractorBJT3Transistor class with the extension of a substrate terminal and corresponding substrate terminal output (annotation) layer.

Two new layers are introduced:

- 'S' - the bulk (substrate) layer. Currently this layer is ignored and can be empty.
- 'tS' - the bulk terminal output layer (defaults to 'S').

The bulk terminal layer ('tS') can be an empty layer representing the wafer substrate. In this use mode the substrate terminal shapes will be produced on the 'tS' layer. This layer then needs to be connected to a global net to establish the net connection.

The device class produced by this extractor is DeviceClassBJT4Transistor. The This class is a closed one and methods cannot be reimplemented. To reimplement specific methods, see DeviceExtractor.

This class has been introduced in version 0.26.

Public constructors

new DeviceExtractorBJT4Transistor ptr	**new**	(string name, DeviceClassFactory ptr factory = none)	Creates a new device extractor with the given name

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference
	void	**_manage**	Marks the object as managed by the script side.
	void	**_unmanage**	Marks the object as no longer owned by the script side.

Detailed description

_create

Signature: void _create

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

new

Signature: *[static]* new DeviceExtractorBJT4Transistor ptr **new** (string name, DeviceClassFactory ptr factory = none)

Description: Creates a new device extractor with the given name

For the 'factory' parameter see DeviceClassFactory. It has been added in version 0.27.3.

Python specific notes:
This method is the default initializer of the object.

4.165. API reference - Class DeviceExtractorDiode

Notation used in Ruby API documentation

Module: db

Description: A device extractor for a planar diode

Class hierarchy: DeviceExtractorDiode » DeviceExtractorBase

This class supplies the generic extractor for a planar diode. The diode is defined by two layers whose overlap area forms the diode. The p-type layer forms the anode, the n-type layer the cathode.

The device class produced by this extractor is DeviceClassDiode. The extractor extracts the two parameters of this class:

- 'A' - the diode area in square micrometer units.
- 'P' - the diode perimeter in micrometer units.

The device layers are:

- 'P' - the p doped area.
- 'N' - the n doped area.

The diode region is defined by the overlap of p and n regions.

The terminal output layers are:

- 'tA' - anode. Defaults to 'P'.
- 'tC' - cathode. Defaults to 'N'.

This class is a closed one and methods cannot be reimplemented. To reimplement specific methods, see DeviceExtractor.

This class has been introduced in version 0.26.

Public constructors

new DeviceExtractorDiode ptr	**new**	(string name, DeviceClassFactory ptr factory = none)	Creates a new device extractor with the given name

Public methods

	void	**_create**	Ensures the C++ object is created
	void	**_destroy**	Explicitly destroys the object
[const]	bool	**_destroyed?**	Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**	Returns a value indicating whether the reference is a const reference
	void	**_manage**	Marks the object as managed by the script side.
	void	**_unmanage**	Marks the object as no longer owned by the script side.

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

new

Signature: *[static]* new DeviceExtractorDiode ptr **new** (string name, DeviceClassFactory ptr factory = none)

Description: Creates a new device extractor with the given name

For the 'factory' parameter see DeviceClassFactory. It has been added in version 0.27.3.

Python specific notes:

This method is the default initializer of the object.

4.166. API reference - Class Connectivity

Notation used in Ruby API documentation

Module: db

Description: This class specifies connections between different layers.

Connections are build using connect. There are basically two flavours of connections: intra-layer and inter-layer.

Intra-layer connections make nets begin propagated along different shapes on the same net. Without the intra-layer connections, nets are not propagated over shape boundaries. As this is usually intended, intra-layer connections should always be specified for each layer.

Inter-layer connections connect shapes on different layers. Shapes which touch across layers will be connected if their layers are specified as being connected through inter-layer connect.

All layers are specified in terms of layer indexes. Layer indexes are layout layer indexes (see Layout class).

The connectivity object also manages the global nets. Global nets are substrate for example and they are propagated automatically from subcircuits to circuits. Global nets are defined by name and are managed through IDs. To get the name for a given ID, use global_net_name. Starting with version 0.29, soft connections are supported. Soft connections attach to high-ohmic substrate or diffusion layers (the 'lower' layer) are upon netlist extraction it will be checked that no wiring is routed over such connections. See soft_connect and soft_global_connect for details.

This class has been introduced in version 0.26.

Public constructors

new Connectivity ptr	**new**		Creates a new object of this class

Public methods

	void	**_create**		Ensures the C++ object is created
	void	**_destroy**		Explicitly destroys the object
[const]	bool	**_destroyed?**		Returns a value indicating whether the object was already destroyed
[const]	bool	**_is_const_object?**		Returns a value indicating whether the reference is a const reference
	void	**_manage**		Marks the object as managed by the script side.
	void	**_unmanage**		Marks the object as no longer owned by the script side.
	void	**assign**	(const Connectivity other)	Assigns another object to self
	void	**connect**	(unsigned int layer)	Specifies intra-layer connectivity.
	void	**connect**	(unsigned int layer_a, unsigned int layer_b)	Specifies inter-layer connectivity.
	unsigned long	**connect_global**	(unsigned int layer, string global_net_name)	Connects the given layer to the global net given by name.

[const]	new Connectivity ptr	**dup**		Creates a copy of self
	unsigned long	**global_net_id**	(string global_net_name)	Gets the ID for a given global net name.
[const]	string	**global_net_name**	(unsigned long global_net_id)	Gets the name for a given global net ID.
	void	**soft_connect**	(unsigned int layer_a, unsigned int layer_b)	Specifies a soft connection between layer_a and layer_b.
	unsigned long	**soft_connect_global**	(unsigned int layer, string global_net_name)	Soft-connects the given layer to the global net given by name.

Deprecated methods (protected, public, static, non-static and constructors)

	void	**create**	Use of this method is deprecated. Use _create instead
	void	**destroy**	Use of this method is deprecated. Use _destroy instead
[const]	bool	**destroyed?**	Use of this method is deprecated. Use _destroyed? instead
[const]	bool	**is_const_object?**	Use of this method is deprecated. Use _is_const_object? instead

Detailed description

_create

Signature: void **_create**

Description: Ensures the C++ object is created

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

_destroy

Signature: void **_destroy**

Description: Explicitly destroys the object

Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.

_destroyed?

Signature: *[const]* bool **_destroyed?**

Description: Returns a value indicating whether the object was already destroyed

This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.

_is_const_object?

Signature: *[const]* bool **_is_const_object?**

Description: Returns a value indicating whether the reference is a const reference

This method returns true, if self is a const reference. In that case, only const methods may be called on self.

_manage

Signature: void **_manage**

Description: Marks the object as managed by the script side.

After calling this method on an object, the script side will be responsible for the management of the object. This method may be called if an object is returned from a C++ function and the object is known not to be owned by any C++ instance. If necessary, the script side may delete the object if the script's reference is no longer required.

Usually it's not required to call this method. It has been introduced in version 0.24.

_unmanage

Signature: void **_unmanage**

Description: Marks the object as no longer owned by the script side.

Calling this method will make this object no longer owned by the script's memory management. Instead, the object must be managed in some other way. Usually this method may be called if it is known that some C++ object holds and manages this object. Technically speaking, this method will turn the script's reference into a weak reference. After the script engine decides to delete the reference, the object itself will still exist. If the object is not managed otherwise, memory leaks will occur.

Usually it's not required to call this method. It has been introduced in version 0.24.

assign

Signature: void **assign** (const Connectivity other)

Description: Assigns another object to self

connect

(1) Signature: void **connect** (unsigned int layer)

Description: Specifies intra-layer connectivity.

This method specifies a hard connection between shapes on the given layer. Without specifying such a connection, shapes on that layer do not form connection regions.

(2) Signature: void **connect** (unsigned int layer_a, unsigned int layer_b)

Description: Specifies inter-layer connectivity.

This method specifies a hard connection between shapes on layer_a and layer_b.

connect_global

Signature: unsigned long **connect_global** (unsigned int layer, string global_net_name)

Description: Connects the given layer to the global net given by name.

Returns the ID of the global net.

create

Signature: void **create**

Description: Ensures the C++ object is created

Use of this method is deprecated. Use _create instead

Use this method to ensure the C++ object is created, for example to ensure that resources are allocated. Usually C++ objects are created on demand and not necessarily when the script object is created.

destroy

Signature: void **destroy**

Description: Explicitly destroys the object

Use of this method is deprecated. Use _destroy instead

	Explicitly destroys the object on C++ side if it was owned by the script interpreter. Subsequent access to this object will throw an exception. If the object is not owned by the script, this method will do nothing.
destroyed?	**Signature**: *[const]* bool **destroyed?** **Description**: Returns a value indicating whether the object was already destroyed Use of this method is deprecated. Use _destroyed? instead This method returns true, if the object was destroyed, either explicitly or by the C++ side. The latter may happen, if the object is owned by a C++ object which got destroyed itself.
dup	**Signature**: *[const]* new Connectivity ptr **dup** **Description**: Creates a copy of self **Python specific notes:** This method also implements '__copy__' and '__deepcopy__'.
global_net_id	**Signature**: unsigned long **global_net_id** (string global_net_name) **Description**: Gets the ID for a given global net name.
global_net_name	**Signature**: *[const]* string **global_net_name** (unsigned long global_net_id) **Description**: Gets the name for a given global net ID.
is_const_object?	**Signature**: *[const]* bool **is_const_object?** **Description**: Returns a value indicating whether the reference is a const reference Use of this method is deprecated. Use _is_const_object? instead This method returns true, if self is a const reference. In that case, only const methods may be called on self.
new	**Signature**: *[static]* new Connectivity ptr **new** **Description**: Creates a new object of this class **Python specific notes:** This method is the default initializer of the object.
soft_connect	**Signature**: void **soft_connect** (unsigned int layer_a, unsigned int layer_b) **Description**: Specifies a soft connection between layer_a and layer_b. **layer_a**: The 'upper' layer **layer_b**: The 'lower' layer Soft connections are made between a lower and an upper layer. The lower layer conceptually is a high-ohmic (i.e. substrate, diffusion) region that is not intended for signal wiring. The netlist extraction will check that no routing happens over such regions. Soft connections have in introduced in version 0.29.
soft_connect_global	**Signature**: unsigned long **soft_connect_global** (unsigned int layer, string global_net_name) **Description**: Soft-connects the given layer to the global net given by name. Returns the ID of the global net. See soft_connect for a description of the soft connection feature. The global net is always the 'lower' (i.e. high-ohmic, substrate) part of the soft connection.

Soft connections have in introduced in version 0.29.

4.167. API reference - Class LayoutToNetlist

Notation used in Ruby API documentation

Module: db

Description: A generic framework for extracting netlists from layouts

Sub-classes: BuildNetHierarchyMode

This class wraps various concepts from db::NetlistExtractor and db::NetlistDeviceExtractor and more. It is supposed to provide a framework for extracting a netlist from a layout.

The use model of this class consists of five steps which need to be executed in this order.

- Configuration: in this step, the LayoutToNetlist object is created and if required, configured. Methods to be used in this step are threads=, area_ratio= or max_vertex_count=. The constructor for the LayoutToNetlist object receives a RecursiveShapeIterator object which basically supplies the hierarchy and the layout taken as input.
- Preparation In this step, the device recognition and extraction layers are drawn from the framework. Derived can now be computed using boolean operations. Methods to use in this step are make_layer and its variants. Layer preparation is not necessarily required to happen before all other steps. Layers can be computed shortly before they are required.
- Following the preparation, the devices can be extracted using extract_devices. This method needs to be called for each device extractor required. Each time, a device extractor needs to be given plus a map of device layers. The device layers are device extractor specific. Either original or derived layers may be specified here. Layer preparation may happen between calls to extract_devices.
- Once the devices are derived, the netlist connectivity can be defined and the netlist extracted. The connectivity is defined with connect and its flavours. The actual netlist extraction happens with extract_netlist.
- After netlist extraction, the information is ready to be retrieved. The produced netlist is available with netlist. The Shapes of a specific net are available with shapes_of_net. probe_net allows finding a net by probing a specific location.

You can also use the extractor with an existing DeepShapeStore object or even flat data. In this case, preparation means importing existing regions with the register method. If you want to use the LayoutToNetlist object with flat data, use the 'LayoutToNetlist(topcell, dbu)' constructor. If you want to use it with hierarchical data and an existing DeepShapeStore object, use the 'LayoutToNetlist(dss)' constructor.

This class has been introduced in version 0.26.

Public constructors

new LayoutToNetlist ptr	**new**	(const RecursiveShapeIterator iter)	Creates a new extractor connected to an original layout
new LayoutToNetlist ptr	**new**		Creates a new and empty extractor object
new LayoutToNetlist ptr	**new**	(DeepShapeStore ptr dss)	Creates a new extractor object reusing an existing DeepShapeStore object
new LayoutToNetlist ptr	**new**	(DeepShapeStore ptr dss, unsigned int layout_index)	Creates a new extractor object reusing an existing DeepShapeStore object
new LayoutToNetlist ptr	**new**	(string topcell_name, double dbu)	Creates a new extractor object with a flat DSS

Public methods

void	**_create**	Ensures the C++ object is created
void	**_destroy**	Explicitly destroys the object

[const]	bool	_destroyed?		Returns a value indicating whether the object was already destroyed
[const]	bool	_is_const_object?		Returns a value indicating whether the reference is a const reference
	void	_manage		Marks the object as managed by the script side.
	void	_unmanage		Marks the object as no longer owned by the script side.
	Region	antenna_check	(const Region gate, const Region metal, double ratio, variant[] diodes = [], Texts ptr texts = nil)	Runs an antenna check on the extracted clusters
	Region	antenna_check	(const Region gate, double gate_perimeter_factor, const Region metal, double metal_perimeter_factor, double ratio, variant[] diodes = [], Texts ptr texts = nil)	Runs an antenna check on the extracted clusters taking the perimeter into account
	Region	antenna_check	(const Region gate, double gate_area_factor, double gate_perimeter_factor, const Region metal, double metal_area_factor, double metal_perimeter_factor, double ratio, variant[] diodes = [], Texts ptr texts = nil)	Runs an antenna check on the extracted clusters taking the perimeter into account and providing an area factor
[const]	double	area_ratio		Gets the area_ratio parameter for the hierarchical network processor
	void	area_ratio=	(double r)	Sets the area_ratio parameter for the hierarchical network processor
[const]	void	build_all_nets	(const CellMapping cmap, Layout target, map<unsigned int,const Region ptr> lmap, variant net_cell_name_prefix = nil, variant netname_prop = nil, LayoutToNetlist::BuildNetHierarchyMode hier_mode = BNH_Flatten, variant circuit_cell_name_prefix = nil,	Builds a full hierarchical representation of the nets

			variant device_cell_name_prefix = nil)	
[const]	void	**build_net**	(const Net net, Layout target, Cell target_cell, map<unsigned int,const Region ptr> lmap, variant netname_prop = nil, LayoutToNetlist::BuildNetHier hier_mode = BNH_Flatten, variant circuit_cell_name_prefix = nil, variant device_cell_name_prefix = nil)	Builds a net representation in the given layout and cell
[const]	void	**build_nets**	(const Net ptr[] nets, const CellMapping cmap, Layout target, map<unsigned int,const Region ptr> lmap, variant net_cell_name_prefix = nil, variant netname_prop = nil, LayoutToNetlist::BuildNetHierarchyMode hier_mode = BNH_Flatten, variant circuit_cell_name_prefix = nil, variant device_cell_name_prefix = nil)	Like build_all_nets, but with the ability to select some nets.
	CellMapping	**cell_mapping_into**	(Layout layout, Cell cell, bool with_device_cells = false)	Creates a cell mapping for copying shapes from the internal layout to the given target layout.
	CellMapping	**cell_mapping_into**	(Layout layout, Cell cell, const Net ptr[] nets, bool with_device_cells = false)	Creates a cell mapping for copying shapes from the internal layout to the given target layout.
	void	**check_extraction_erro**		Raises an exception if extraction errors are present
	void	**clear_join_net_names**		Clears all implicit net joining expressions.
	void	**clear_join_nets**		Clears all explicit net joining expressions.
	void	**connect**	(const Region l)	Defines an intra-layer connection for the given layer.

	void	**connect**	(const Region a, const Region b)	Defines an inter-layer connection for the given layers.
	void	**connect**	(const Region a, const Texts b)	Defines an inter-layer connection for the given layers.
	void	**connect**	(const Texts a, const Region b)	Defines an inter-layer connection for the given layers.
	unsigned long	**connect_global**	(const Region l, string global_net_name)	Defines a connection of the given layer with a global net.
	unsigned long	**connect_global**	(const Texts l, string global_net_name)	Defines a connection of the given text layer with a global net.
	CellMapping	**const_cell_mapping_into**	(const Layout layout, const Cell cell)	Creates a cell mapping for copying shapes from the internal layout to the given target layout.
[const]	string	**description**		Gets the description of the database
	void	**description=**	(string description)	Sets the description of the database
[const]	double	**device_scaling**		Gets the device scaling factor
	void	**device_scaling=**	(double f)	Sets the device scaling factor
	DeepShapeStore	**dss**		Gets a reference to the internal DSS object.
[const,iter]	LogEntryData	**each_log_entry**		Iterates over all log entries collected during device and netlist extraction.
	void	**extract_devices**	(DeviceExtractorBase extractor, map<string,ShapeCollection ptr> layers)	Extracts devices
	void	**extract_netlist**		Runs the netlist extraction
[const]	string	**filename**		Gets the file name of the database
[const]	string	**generator**		Gets the generator string.
	void	**generator=**	(string generator)	Sets the generator string.
[const]	string	**global_net_name**	(unsigned long global_net_id)	Gets the global net name for the given global net ID.
